Zonal Necrosis of the Liver.—Dr. E. L. OPIE of Baltimore read this paper and stated that the hepatic lobule could be divided into three zones, each of which might be the seat of coagulation necrosis affecting the parenchymatous cells. In fourteen instances the lesion formed a circular bandlike zone situated between the center and the periphery of the lobule, while in other cases similar necrosis had been limited either to the central or to the peripheral zone unaffected in the former cases. Such necrosis depended upon the presence in the blood of toxic substances usually produced by pyogenic bacteria, and the distribution of the lesion was the result of peculiar conditions of circulation within the lobule. By experimental injections it had been possible to demonstrate in lower animals the presence of a mid-zone which differed from other parts of the lobule. Zonal necrosis was frequently associated with fatty degeneration and was closely related to acute yellow atrophy of the liver. The results obtained were from the use of some granular material or stain, and he came to the conclusion that both the hepatic artery and the portal vein entered the lobule and soon joined a short distance from the periphery. The granular material was left throughout the lobule. But if the hepatic artery was ligated and then the granular material injected through the portal vein, it would lodge entirely in the periphery of the lobule, and this proved to him that the hepatic artery was an important factor in driving the portal blood through the lobule. When an ammoniacal solution of carmine was injected into the portal vein and the animal allowed to live about fifteen minutes this substance was found to be accumulated between the peripheral and central zone. In 500 autopsies 12 cases of central necrosis were found, and all were associated with some circulatory disturbance, but doubtless there was an etiological factor in some form of infection with the streptococcus aureus; in the cases the necrosis was entirely limited to this area, and all cases were associated with pregnancy. In 3 cases there was this condition in contact with the portal spaces and associated with eclampsia. In the 500 cases the mid-zone lesion was present in 9, and he had collected 5 more from the literature, making 14 altogether. In these cases the mid-zone necrosis was well marked. In most cases there was associated a fatty degeneration. Of these 14 cases 6 occurred with peritonitis, and the bacterial examination showed the streptococcus aureus in 3 of them. In 3 other cases lesions of the gastrointestinal tract were the predominate features.

Exhibitions of Specimen of a Malignant Adenoma of the Liver.—Dr. GEORGE L. PEABODY of New York demonstrated such a liver showing large malignant adenoma in a case of trophic, probably syphilitic, cirrhosis. Death was from exhaustion preceded by hemorrhage from the

tumor into the peritoneum. The patient from whom it was removed was a Greek, thirty-eight years old, who was admitted to New York Hospital October 5. He denied syphilis and alcoholism, although he drank beer. His illness lasted but a short time prior to his admission. He complained only of ascites and the accompanying interference with respiration. None of the solid viscera could be made out. He was tapped and 7½ litres of a bloody serum withdrawn. In this serum there were 697,000 red cells to the cm. and the smear looked like the ordinary blood smears. This tapping relieved him but a few days when he was in a similar condition. After the first tapping the spleen and liver were not palpable, but on percussion they could be made out and shown to be quite small. The patient failed rapidly and died about one month after he entered the hospital. The peritoneum was found to contain 3½ liters of bloody fluid, and its source was found to be from an irregular mass, 7 cm. in diameter from the upper surface of the right lobe of the liver. Some of the lymph glands in the mesentery and the bronchial lymph nodes were enlarged. The lungs contained very small infarctions. The mouth of one of the main hepatic veins had projecting from it a villous mass about 1½ cm. in diameter. The splenic vein was thrombosed. The liver itself was very much reduced in size and altered in shape. The extreme measurements gave 15 in the vertical, 14 in the transverse and 10 in the antero-posterior directions. There was a marked atrophic cirrhosis of that organ and, upon its surface, many cicatricial contractions. There was no quadrate lobe at all. There was one projecting mass, covered over by Glisson's capsule which originated from the liver substance. In many parts of the liver the tumor tissue could be demonstrated, and appeared to be soft and greenish in color. The microscopical examination of the liver showed the ordinary lesions of an advanced hypertrophic cirrhosis with broad bands of cicatricial tissue, such as seen in syphilitic cirrhosis. The tumor was uniform, contained no bile, and presented the trabecular variety of adenoma. The liver cells were very distinctly modified, showing large nuclei, and as many as two or three. No metastatic growths were found. Sections of the growth were shown under the microscope.

Addison's Disease with and without Adrenal Tuberculosis.—Dr. C. F. WITHINGTON of Boston read this paper. He divided these cases into the following classification:

I. Cases with Skin Bronzing. (*a*) Advanced tuberculosis. (*b*) Advanced disease, non-tuberculous (atrophy, interstitial inflammation, cancer, occlusion vein, hemorrhage). (*c*) No distinct disease as (1) with lesion of the semilunar ganglion, (2) without lesion of semilunar ganglion, and (3) pigmentation not Addison's disease.

II. Cases without Skin Bronzing. (*a*) Adrenal tuberculosis, (1) with tuberculosis elsewhere and (2) without tuberculosis elsewhere. (*b*) Addison's disease non-tubercular (1) in cancer, (2) in tumors, and (3) necrosis, etc. Among these he referred to sixteen cases of miscellaneous adrenal lesions, including tuberculosis, without skin-bronzing.

Arthritis and Endocarditis from Streptococcus Infection.—Dr. MORRIS J. LEWIS of Philadelphia presented this paper and said that the question of rheumatic fever being an acute infectious disease had long been disputed and few authorities agreed as to its true etiology. The results of studies by different people were very contradictory. The relationship between chorea and rheumatism was very interesting. He reported the case of a woman who came under observation in October, 1903, with a history of painful swelling of the ankle. The condition was improved by the administration of salicylic acid. She had choreic movements of the hands and face and the movements at times were so violent that they were forced to tie her in bed. When admitted to the hospital the temperature was not taken, there was no heart murmur, and the pulse and respirations were rapid. The day following her admission the temperature suddenly went up to 107 and the choreic movements became excessively violent. By sponging, the temperature fell to 101 but the choreic movements did not diminish. On the day following, a systolic murmur was heard and the temperature rose to 106. Blood culture was taken on the afternoon of the day of death, and streptococci were found which were moderately virulent for rabbits when injected intravenously. The onset of the joint symptoms in these animals was only noticed after a more or less definite incubation period of from four to nine days. Before this the animals appeared to be perfectly well. Then the joints appeared to be swollen and painful and the streptococci could be recovered from all the affected joints.

Officers Elected.—*President*, Dr. Edward L. Trudeau, Saranac Lake; *Vice-President*, Dr. Frank Billings, Chicago; *Secretary*, Dr. Henry Hun, Albany; *Recorder*, Dr. Solomon Solis Cohen, Philadelphia; *Treasurer*, Dr J. P. Crozier Griffith, Philadelphia; *Councillor*, Dr. F. Forchheimer, Cincinnati; *Representative in the Executive Committee of the Congress of American Physicians and Surgeons*, Dr. William Osler, Baltimore; *Alternate Representative*, Dr. Francis H. Williams, Boston.

The following gentlemen were elected to membership; Dr. Philip King Brown of San Francisco, Dr. Joseph Collins of New York, Dr. David L. Edsall of Philadelphia, Dr. Frederick Gault Finley of Montreal, Dr Hermon C. Gordinier of Troy, Dr. Richard M. Pearce of Albany, Dr. Mark W. Richardson of Boston, and Dr. Richard P. Strong, U. S. A. To honorary membership the following were elected: Drs. Beverly Robinson, Starling Loving, and Henry G. Walcott.

CHICAGO SURGICAL SOCIETY.

At the April meeting, Dr. Arthur Dean Bevan showed a young man, who gave a history of pneumonia, and a metapneumonic empyema. A rib had been resected, and an empyema of the left side drained eight months before by another surgeon, after which the opening closed. This was followed by a reaccumulation of the fluid, and when he saw the patient the entire left side of the chest was full of pus up to the clavicle, and the apex beat was in the middle line. He took an *x*-ray view of the case, which showed fairly well the condition. There was a small discharging fistula in the third intercostal space, two inches to the left of the sternum, and through this a probe could outline the entire cavity. The patient was septic, and in bad condition. A Schèdè operation was done. An extensive U-shaped incision was made, and the soft tissues lifted up. A resection was made from the third rib to the tenth inclusive. This was done subperiosteally. After lifting up a very large flap, and after the resection had been made, he took a powerful pair of scissors and cut away all of the intercostal tissues, including the pleura, which was three-quarters of an inch in thickness. This U-shaped flap was drawn down and a tube as large as the thumb introduced to the apex of the cavity, and the flap stitched in position. Some gauze was also packed in. The operation was done the 7th of January. The patient had some sepsis for a considerable period after the operation, about ten days; in other words, the temperature continued. However, his condition gradually improved, and within a short time, he thought four weeks after the operation, he outlined the size of the cavity which remained, and it was done in this way: He injected iodoform emulsion into the cavity, sealed the opening, and took an *x*-ray picture. The skiagraph showed a cavity which reached almost to the clavicle, it being a fine ribbon-like cavity. After he had outlined this cavity with the iodoform emulsion, he put the patient at work blowing up an air-bag. This was responsible for the complete cure which had taken place, and the obliteration of this long, ribbon-like cavity that extended to the apex. This was the seventh or eighth Schèdè opera-

ion he had done, and it was the most satisfactory one of he entire group.

Dr. D. W. Graham reported "Appendicitis with Perforation of the Duodenum" in a patient aged thirty-seven. After detailing the steps of the operation that had been performed, as well as mentioning the death of the patient on the tenth day following operation, at the autopsy the appendix measures 11 centimeters in length, and was found to pass directly upward behind the ascending colon, its free end being adherent to the psoas muscle, and lying behind the curve of the duodenum and attached to it. Six centimeters from the pylorus and on a level with and three centimeters to the right of the biliary papilla, was a perforation of the posterior duodenal wall three millimeters in diameter. He presented a specimen showing the relation of the appendix to the colon, the abscess cavity, and the duodenum.

Dr. Graham also reported a case of "Amœbic Abscess of the Liver, with Complication," and exhibited specimen. The patient was a man, thirty-seven years of age. The specimen showed (1) the large sloughing wound of the abdominal wall, which had been preserved intact; (2) the adhesion of the liver to the colon, which represented the point where the abscess was partially evacuated through the colon wall before the operation; (3) the abscess cavity in the liver as large as a fist, notwithstanding the contraction that had taken place; (4) many small abscesses through the liver; (5) numerous ulcers in the mucosa of the colon, with sloughing undermined edges and intercommunicating by channels underneath the mucosa, having all the characteristic features of amœbic ulceration.

Dr. D. N. Eisendrath showed a skiagraph from a patient, fifty-six years of age, who consulted him on account of recurrent hemorrhages, apparently from the lungs. The skiagraph showed beautifully a cervical rib. As regards the origin of this cervical rib, the only way one could understand it was to consider the ribs as a revelation of type of the mammalia toward some of the elementary forms. This cervical rib existed in reptiles. It must be regarded as an abnormal development of the anterior nucleus of the transverse process of the seventh cervical vertebra.

Dr. D. N. Eisendrath reported a case of "Adenoma of the Mucous Glands of the Lips as a Cause of Macrocheilia." He said that this condition consisted in an enormous thickening of either the upper or lower lip, or both, and occurred especially in scrofulous children, was very apt to relapse, and often very chronic in character. Microscopically, it consisted of an hypertrophy of the mucous glands, with an increase of all of the tissues constituting the lip, the connective tissue, blood-vessels, etc. It also occurred at times in syphilis. Operation was successful, with no recurrence of the disease since its performance.

Dr. A. E. Halstead reported the case of a child, eight years of age, who had an extensive empyema of two years' duration. He resorted to extensive resection of the ribs, except the second one. He found difficulty in getting the cavity closed under the scapula. There was a high cavity which extended away up to the second rib, and so far as he knew, as he had not seen the child for a month, this cavity was still open.

Dr. Charles Davison read a paper entitled "Results in Abdominal Wall Suture." Some time ago the author proposed the fastening of a longitudinal silkworm gut suture in the fascia of the abdominal wall by terminal bowknots, leaving the ends of the suture protruding from the wound; the knots to be untied by traction on the exposed ends and the suture removed at the completion of the process of healing. A complete series of forty-one consecutive cases with sterile primary union was reported at that time. The aim of this simple manipulation was to retain all of the advantages and security of close and accurate suture of the individual layers of the abdominal wall, without the danger of suppuration incident to the use of catgut, and its pulpification and absorption, and without the dangers of irritation and sinus following the use of any permanent buried suture. The writer had used the tied longitudinal silkworm gut suture in all clean laparotomies during the three years, 1901-2-3, with the following results: 178 cases with 7 infections, or less than 4 per cent. of infections. Of these cases, 23 were emergencies, operated upon without previous preparation, with 4 cases showing infection, all limited to the subcutaneous fat. The remaining 150 cases had hospital preparation previous to the operation, with 3 cases of infection, or less than 2 per cent. of suppuration in the prepared cases. Of the writer's 178 cases of removable silkworm gut suture, 131 had been followed up to the time of the preparation of this report. One case of spontaneous epigastric hernia operated upon by Mayo's method had a recurrence of hernia two inches from the old line of incision five months after operation, ¾ of 1 per cent. of post-operative ventral hernias. Dr. A. J. Ochsner said there were three elements which must be considered in the closure of abdominal wounds. First, accurate coaptation; second, an aseptic wound, and third, the absence of pressure necrosis. If these three conditions were carried out, it did not make much difference what suture material was used, or what particular method one employed, he would not get post-operative hernia. Last year he had approximately seven hundred and forty abdominal sections, and of this number he did not think there would be a ventral hernia in which the three principles referred to were carried out. Dr. D. N. Eisendrath had seen the method of Dr. Davison used very satisfactorily. Dr. Wm. M. Harsha said he had used Dr. Davison's suture method in probably twenty or more cases. There had been no hernia in any of the cases he had been able to follow up; but the skin cicatrix had spread in some cases. He had had no case of infection. By this method it made the neatest and nicest scar when one removed the sutures. Dr. C. C. Rogers had used the Davison suture in 18 cases, 5 of them being emergency cases, the others hospital cases, with 1 case of infection. In 13 there had been no hernia; the others he had not seen or heard of recently. Dr. Carl Wagner had used the longitudinal wire suture in several cases, but had abandoned it on account of the wound in two cases having opened. He thought the wire was too stiff. Silkworm gut was preferable, for the reason that it was much smoother and more elastic. Dr. E. Wyllys Andrews said that one virtue of the longitudinal silkworm gut stitch lay in the fact that it was semi-rigid and semi-flexible, becoming molded to the tissues and not stretching. Dr. Wm. E. Schroeder read a paper in which he discussed subparietal injuries of the gastrointestinal tract, and reported cases. Dr. Wm. Hessert reported a case in which he resected four feet of the intestine for perforation of the uterus during curettage. Dr. Hessert also detailed an interesting case of carcinoma of the head of the pancreas.

The Regeneration of the Ligated Saphenous Vein.—Ledderhose says that considerable differences of opinion have existed as to whether it is possible for divided veins to regenerate and again become permeable for the blood stream. The opponents of the regeneration theory have maintained that in the cases in which re-establishment of the circulation had taken place it was always the result of collateral branches developing and taking up the work formerly done by the divided vessel, but he describes two cases of his own in which the saphenous vein had been ligated for varicosities of the legs and the ends had been found reunited years afterward. The secondary operation was done in the one case seven years and in the other nine years after the original ligation. The gross and microscopical appearances of the specimens obtained bears out the view that regeneration of such veinous trunks is possible. No traces of the silk ligatures used at the original operation could be found.—*Deutsche Zeitschrift für Chirurgie*, 1904, Vol. 71, No. 4.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending May 7, 1904:

	Cases.	Deaths.
Measles	1836	39
Diphtheria and croup	382	40
Scarlet fever	391	23
Smallpox	1	...
Varicella	78	...
Tuberculosis	411	197
Typhoid fever	18	8
Cerebrospinal meningitis	...	77

Delirium Grave.—William Broaddus Pritchard declares that in one detail only is there absolute unanimity of opinion in regard to this affection which he discusses. All authors agree that the disease is very uncommon. Even the nomenclature is most confusing. The affection is peculiar to women and the period of greatest susceptibility is between the ages of twenty-five and forty-five. The diagnosis ought to be clear in typical cases. Sudden, furious maniacal delirium, with fever, active vasomotor, and sometimes trophic disturbances, vicious insomnia, refusal of food, incontinence of urine and fæces, incoherence in every direction, with repeated remissions, followed by exhaustion, collapse and death in a few days or a week or two, especially when occurring in a middle-aged woman, without assignable cause, except in some severe mental strain cannot well be mistaken for anything else. The disease is of extremely grave prognosis. As to treatment, some plan involving the principles of autointoxication medication seems most positively indicated. The writer has found the use of all drugs disappointing. Physical suppression, forced nutrition, symptomatic sedative drugging, and active eliminant medication would at least appear to be rational. The writer believes the field to be one for legitimate experimentation, which promises most if conducted along the lines of either neutralizing sera or active antisepsis.—*The Journal of Nervous and Mental Disease.*

The Etiology of Sleeping Sickness.—Castellani examined the cerebrospinal fluid of thirty-four patients affected with sleeping sickness and in twenty found a trypanosome which he regards as the causative agent of the disease. In two cases it was obtained post mortem from the fluid in the lateral ventricles and in one case of the few examined in this way, it was discovered in the blood. The author's method is to obtain at least 5 c.c. of cerebrospinal fluid by lumbar puncture, discarding the first few c.c. as they are likely to contain blood. As soon as the fluid flows clear 10 c.c. are collected and centrifuged for fifteen minutes. The resulting scanty white sediment is examined with a moderate magnifying power and the actively motile trypanosomes easily recognized. The parasites are 16–24 μ in length and 2–2.5 μ in breadth and are made up of a protoplasmic body tapering at one end into a flagellum while the other is more or less rounded and possesses an undulating membrane and a vacuole. Motion is active at first, in the direction of the rounded end, but gradually ceases, frequently in the neighborhood of a leucocyte. Leishman's stain colors the large nucleus and the flagellum red, while the protoplasm is blue and the undulating membrane does not stain. Chromatin bodies are present. In the circulating blood, particularly in the latter stages of the disease round bodies of a diameter of 8–12 μ and with one or more vacuoles are to be found and the same bodies also occur in the cerebrospinal fluid. The author regards these as a developmental stage in the life history of the organism. It is probable that the infection is conveyed by the bite of an insect.—*Zentralblatt für Bakteriologie.*

The Early Manifestations of Cirrhosis of the Liver Previous to the Appearance of Physical Signs.—Charles G. Stockton declares that when the question is subject to careful scrutiny and analysis, there seems to be no positive data, from a clinical standpoint, upon which a developing hepatic cirrhosis can be predicted. The writer gives the history of two non-alcoholic patients. The former is still living. Physical examination in this case gives evidence of an extremely small liver. The skin is not clear and the patient has to be extremely careful about his diet. The trouble has come on gradually over a period of fifteen to twenty years. Another patient showed somewhat the same symptoms. He suffered from bilious attacks. He was always relieved by abstinence from eating and by purgation. Autopsy revealed cirrhosis of the liver. In order to reach any definite conclusions on this subject it must be from the early study of those cases of hepatic cirrhosis which occur in the non-alcoholic. —*University of Pennsylvania Medical Bulletin.*

Health Report.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, U. S. Marine Hospital Service, during the week ended May 7, 1904:

THE TREATMENT OF PNEUMONIA.*

BY JOSÉ M. FERRER, M.D.,
NEW YORK.
VISITING PHYSICIAN TO THE ST. VINCENT'S HOSPITAL AND THE FRENCH HOSPITAL, NEW YORK.

THE recent great prevalence and high morta ty of pneumonia and the hope of eliciting a review of modern treatment in this disease must justify me in addressing you on a subject seemingly trite and unprofitable. I say trite, because since the days of Hippocrates no disease, perhaps, has been so frequently discussed; and unprofitable, because with every known method of treatment a certain number of patients will die, and without any treatment at all, or even in spite of bad treatment, a certain number will recover. But the last word has not been said on the subject and probably never will be said. Familiar to the profession from time immemorial, this plague of humanity will in all likelihood endure to the end of time.

The older theories of so-called telluric and atmospheric causation have taken secondary rank to the more alluring theory of specific infection by the pneumococcus.

Despite the most varied opinions, it seems fair to conclude that pneumonia is a general blood infection with a selective local manifestation in the lungs. That the disease material may be conveyed by the expectoration, and that this is the most common source of contamination.

With our ability to destroy the activity of this material and to restrict its habitat and with advanced methods in preventive sanitation, the hope is warranted that the next decade will witness a marked diminution in the number of cases. The work of our health boards and our campaign of education should show approximately as good results as in yellow fever, cholera, smallpox, diphtheria, and, in a lesser degree, tuberculosis.

Beset with difficulties and uncertainties, the treatment of pneumonia has been marked by constant changes and vacillations. While the profession has been forever fruitlessly in search of specifics, the cases have been managed alternately with vigorous depletory measures and again with abject expectancy.

Twenty-seven years ago, when I studied medicine, Alonzo Clark still advocated a generous use of the lancet. He related how he and Dr. North frequently bled patients to the extent of 16 ounces. The practice of phlebotomy has been steadily losing ground ever since, and very few will now be found carrying out in practice what theoretically many would still propose.

Calomel had rather gone out of fashion, though Leaming and others contended that cases could be aborted or shortened by liberal doses of this drug.

Most physicians still used tartar emetic and other salts of antimony.

The use of veratrum viride was at the height of its popularity. They gave 5 minim doses of the tincture every two or three hours, or, as some thought better, two or three drops every half hour. Or else they gave $\frac{1}{10}$ of a grain of veratria every three hours.

Aconite was a close second in the treatment of the day, though most men did not think it so safe or reliable as veratrum.

Everyone used quinine in 5 or 10-grain doses t. i. d. The elder Flint believed that cases could be aborted by giving from 20 to 40 grains of quinine within eight or ten hours.

Digitalis was extensive y employed.

Cold affusions to the chest and ice-bags had just been introduced from Germany—I think chiefly through Niemeyer's recommendation—but met with great opposition. Clark stated that four out of six cases died. He also deprecated the use of the general bath at from 60° to 80°, which was being tried at the time.

Alcoholics were employed by most practitioners, in moderation, but rarely before the second stage, and from 6 to 10 ounces of whiskey in the twenty-four hours was considered the limit. The English Dr. Todd, however, used alcoholics in all his cases and in larger doses.

Opium was recommended in the first stage when pain, delirium, and vigilance were present.

Saline purges were employed, when needed. Cups, wet and dry, blisters and poultices were used early.

The oiled silk jacket had been in vogue, but was going out of fashion.

Expectorants with muriate or carbonate of Ammonia were generally used.

The diet was milk and broths.

Later years have witnessed the complete triumph of the expectant plan of treatment. This does not imply that we must refrain from all efforts to relieve our patients, for we can carry them through very frequently in safety and comfort directly through our recommendations when, left unaided, they would perish. Nor does it imply to my mind a mere groping attention to symptoms. I believe we are learning more and more to consider the patient rather than the disease.

Hygienic measures, good nursing, active interference if it is necessary, avoidance of "fussing" and annoying the patient when he is doing well, discretion in the diet and supporting measures, a strict attention to the bowels and the relief of pain, fever, and restlessness, constitute about all we know of the treatment of pneumonia. But it is a great deal.

The facts that pneumonia is a self-limited disease, and that no agents known to us seem to have a curative influence, should not prevent us from putting forth new efforts constantly for the amelioration of our patients.

The modern specifics and vaunted drugs will be dismissed in a few words, because it has seemed to me that they have all been found wanting.

I have used the salicylates frequently and have seen them used systematically and in considerable doses in this disease, and I have failed to be convinced that they were of service. Aspirin I consider equally ineffectual.

*Read at a meeting of the Northwestern Medical and Surgical Society on April 20, 1904.

Creosotal, creosote, and guaiacol I have faithfully tried, and, excepting in certain cases of catarrhal pneumonia with much bronchial secretion, I have abandoned their use.

With digitalis I have little experience, except for specific purposes in cardiac failure, when it seems to act well sometimes.

Latterly, ergot has come again into the field, and various preparations of the drug are being used.

I recall that twenty-five years ago we tried it in Charity Hospital without success. Huss introduced it many years ago. In the few cases in which it has been used lately in St. Vincent's Hospital, the results are not encouraging.

With the iodides I have no experience in acute lobar pneumonia. I have used them in catarrhal pneumonias and in delayed resolution with no marked benefit.

For quinine I confess that I still have a weakness, and in certain cases I give 10 grains twice or thrice a day, or else tonic doses of 3 to 5 grains t. i. d. It seems sometimes to have a decided effect on the temperature and to improve the general aspect of the case. At the French Hospital within the last two months ten of my pneumonia patients treated off and on with this drug alone have done very well. Care should be exercised not to upset the stomach by two long continued use.

The so-called expectorants I have found useless in acute lobar pneumonia.

It is proposed in this paper to give my experience, without the intention of being prolix or dogmatic, and without theorizing on therapeutic action.

Called early to the case, we proceed to make our diagnosis. This done, the condition of the apartment is considered. If the patient is in a small, dark, stuffy room, he is removed at once to a large, airy, and sunny chamber, where he must remain until convalescence is fully established.

Arrangements are immediately made for proper nursing. It is preferable to demand two nurses, selecting the more tactful one for night duty. If nurses are unavailable we must hold some individual in the family responsible for the carrying out of directions, and not permit various members of the family or all of them to "help" in a disorderly and hysterical manner.

The patient must in a measure be isolated, to insure quiet and repose and to avoid possible infection of others. Children and visitors are excluded; only those necessary to the patient's comfort are allowed about at any time.

The patient is undressed and put to bed wearing a night gown, loose jacket, or some garment devised to facilitate physical examinations of the chest without undue discomfort.

The bed should not be too near the windows, in order that ventilation may be obtained at all times without drafts blowing on the patient. There should not be too much covering during the height of the fever.

A room thermometer should be procured and the temperature kept at about 75° or 80° F. Some physicians prefer a temperature of 65° or 70° F.

The towels, napkins, bedding, handkerchiefs, glasses, cups, spoons, etc., should not be used by other members of the family until properly disinfected. Provision should be made for the sputum. A bedside cuspidor or ordinary finger-bowl may be used for this purpose, and they should contain some efficient disinfectant, such as carbolic solution in the strength of 1 to 20. What I think better, is to have prepared pieces of old linen into which the patient expectorates and which he afterward deposits in a receptacle for the purpose. These are removed and burned from time to time. Kissing and fondling the patient should be forbidden.

It is my habit both in hospital and private practice to order no routine treatment to be continued, until stopped, but to give directions from one visit to the next. The nurse takes down these directions from dictation, or, if no nurse is present, I write them out plainly, to avoid mistakes and neglect.

Of course, in a severe case three or even four visits will have to be made in twenty-four hours, and directions for the day may be given at the morning visit, with such modifications as may be necessary at subsequent visits. Some bedside notes should be kept, wherein are recorded all the incidents of the day, the temperature, pulse, respiration, urination, stools, medicines given, with the hours, etc.

For the initial chill usually all that can be done is to wrap the patient up in blankets, apply warmth to the surface by water-bags or hot bottles under the bed clothes, and administer a little warm milk, a cup of tea, or a hot lemonade. Except in alcoholics, whiskey is not desirable. Sometimes gentle friction of the body is grateful.

If the disease is ushered in with nausea and vomiting which may persist for days, very little nourishment should be allowed—indeed, anorexia is the rule in the initial stages. Three or four ounces of milk every three hours will be sufficient, with longer intervals at night.

A mustard plaster may be put over the epigastrium. Oxalate of cerium may be tried in 3 to 5 grain doses. Five grains of calomel and five of bicarbonate of soda may be given, or a tablet of a ½ grain of calomel every half hour until four are taken, to be followed by a saline water.

Usually the sharp cutting pain in the chest will require attention. Hot poultices, changed every half hour for three or four times, afford relief. Penbody recommends the electric warm pad, by means of which a regular temperature can be kept up continuously for some time. Ice-bags applied to the seat of pain certainly give relief, but I think the hot applications are preferable. Sometimes a mustard plaster will ease the pain. Blisters should not be used, except late in unresolving pneumonias. Dry cups have seemed to me to help the patient, and I often use them.

Wet cups do not appeal to me, though some still use them.

If the pain is not relieved by the measures above detailed, or recurs immediately, the affected chest may be strapped, even if it interferes with physical examinations. The pain and restlessness may be so intense that a hypodermic of morphine may be necessary.

The question of opiates in the early stages of pneumonia has constantly evoked contrary opinions. Frequent warnings are repeated through the literature, and in modern discussions many practitioners raise their voices in opposition to their use. I confess that for a long time I had a prejudice against them. The unfavorable course of certain cases was attributed by me to their employment. A larger experience has convinced me, however, that they may often be used with safety and splendid effect. When the patient is suffering from pain and discomfort, in active delirium, obtaining no sleep for days and nights together, restless and irritable, and when cyanosis and œdema are *not* present, I know of nothing that will take the place of a dose of morphine.

Ten grains of Dover's powder may be tried, but will often fail to produce the desired effect. A hypodermic injection of six minims of Magendie's

solution will secure several hours' rest, will even reduce the temperature, quiet excitability and relieve pain and delirium. At St. Vincent's Hospital, where we have had this winter as many as forty cases at one time, hypodermics of Magendie have frequently been given with gratifying results. In the alcoholic cases it has been necessary to administer this drug at some time in the majority of the cases.

Large doses of the bromides, paraldehyde in ʒ ii doses, hyoscine hydrochlorate in $\frac{1}{100}$ to $\frac{1}{60}$ grain hypodermically, though often useful, have at times failed of their purpose. At present, veronal enjoys a certain measure of popularity. I have used it in 7 to 10-grain doses, and while it will induce sleep, in some cases it has seemed to me that it depressed the patient. A further trial is in order before its status can be fixed. Trional, I use very seldom in pneumonia and typhoid fever, because I have seen marked depression follow its use, the temperature dropping to subnormal with signs of imminent collapse. In order to be effectual, considerable doses have to be used—often 30 grains. Sulfonal is too slow and its effects persist through the following day. Paraldehyde, I do not like particularly in pneumonia, because of congestive manifestations and nauseating taste, but when there is an alcoholic foundation it sometimes acts well. The bromides have not given satisfaction in my hands in this disease. Chloral, I do not use on account of its action on the heart. The elixir of chloralamid, however, has sometimes acted well in half-ounce doses.

In catarrhal pneumonias, particularly when there is an asthmatic tendency, a drachm of compound spirits of ether is serviceable, occasionally.

The question of blood-letting is still considered by some practitioners in the first stages of pneumonia. I have no knowledge to offer on the subject. It has been tried at the hospital, but, I think, too late. One can conceive of cases in which it would do good in healthy, full-blooded individuals with engorgement of the right heart, cyanosis and collateral œdema setting in. But the reasons against it are, to my mind, very powerful. Its effect is not certain in all cases. The benefit is only temporary, the same conditions being liable to recur, and no one nowadays would recommend bleeding "coup sur coup."

We rarely get the cases early enough to venture on the procedure. Statistics prove a greater mortality in cases that have been bled. It is admitted that it delays convalescence and leaves the patient anæmic and weak for a long time. Then, again, if the patient does badly, we are blamed and the fatal result is laid at the door of phlebotomy.

The tympanites, which sets in early, sometimes gives considerable trouble. Indeed, some observers declare that a physical examination of the abdomen is more important than a physical examination of the chest. To relieve the distention and clear the intestines, 5 grains of calomel and 5 of soda at one dose, or fractional doses followed by a saline are helpful. Colon irrigations with the long soft tube and warm normal salt solution (ʒ i-Oi) should be tried. If marked constipation exists we may give 20 or 30 grains of compound jalap powder,

Frequently, a milk diet intensifies and prolongs this condition, so that it is necessary sometimes to stop milk and give beef, mutton, and chicken broths, egg water (equal parts of the white of the egg and water), which may be acidulated with lemon-juice or used as a good vehicle for whiskey. The liquid beef peptonoids may be tried. Somatose in 3 i doses every two or three hours may be used for a time if the stomach is disturbed. Sometimes gelatin solution (ʒ i to ʒ xx, acidulated with lemon or dilute nitromuriatic acid, or given with a little whiskey when necessary) is a good dietary makeshift, but patients soon tire of it. Peptonizing the milk by the cold process serves very well on occasion. Five grains of pancreatin t. i. d., may be tried.

Occasionally, 15 to 20 minims of turpentine in mucilage of acacia internally gives relief. Properly applied turpentine stupes still retain their popularity and justly.

When fermentation and distention continues, some give salol, resorcin and soda, or beta naphthol and charcoal, or naphthalin, or creosote, or carbolic acid and camphor. I have seen no good results from these remedies, though I have used them very often.

Enemata of soap-suds and oil or with oxgall or turpentine should be used when needed. Under all circumstances we should secure a daily movement of the bowels.

The fever of the patient is often sufficiently high to engage our attention. I rarely have the rectal temperature taken oftener than once in four hours and very often only once in six hours. The patient should be allowed to drink all the water he wants, and it should be offered to him from time to time. When the temperature is over 103° an occasional sponging with cool water—say, once in four or five hours—is grateful to the patient and does good.

With the tub bath at 60° or 70°, I have no experience in pneumonia. It is seldom necessary and I cannot get over a prejudice against it.

In very high temperatures, no harm will follow the cold pack. Cold compresses to the head, frequently renewed, are most soothing and comforting.

Sometimes gentle fanning quiets and relieves the patient. In long continued fever and marked toxæmia I often give quinine. Ten-grain doses, twice or three times a day, will reduce temperature. I frequently give three or five grains t. i. d. as a tonic.

The cough may be constant and annoying. I have not had very good results in treating this symptom. I have not found that muriate or carbonate of ammonia had an effect either in liquifying the viscid secretion nor in facilitating its expulsion, nor in checking the cough. The so-called expectorants, such as squills, ipecac, sanguinaria, etc., are not now used except in catarrhal pneumonias, when creosote also does some good. Sometimes giving $\frac{1}{12}$ to $\frac{1}{8}$ grain of heroin a couple of times, gives relief. Terpine hydrate in 2 to 5-grain doses may be tried. The patient will instinctively prefer to lie on the affected side, and turning on the other side will start up the coughing. This natural indication should have sway, and we should not exhaust the patient by inducing spells of coughing in making physical examinations too frequently.

Proper ventilation with lots of fresh air, which need not be cold, is helpful. Occasionally oxygen seems to allay irritability, particularly in old persons and in catarrhal and asthmatic cases. It should be used early and be given a fair trial. Many of the laity regard the oxygen can as the forerunner of the hearse because it is often used too late.

Of course our great bugbear in pneumonia is the condition of the heart and vessels. At the earliest sign of failure, sufficiently vigorous stimulation should be at once commenced. Some practitioners believe that it is best to begin stimulation early and forestall progressive heart failure. While believing that it is better to commence too early than too late, I am certain that the use of stimulants is frightfully overdone. It is irrational and harmful to put a patient on half-ounce doses of whiskey every two or three hours and to supplement this by strychnine con-

tinued for many days because we have to deal with a case of pneumonia, and because later there may be cardiac failure, which condition, as a matter of fact, may never develop. It is remarkable what little "support" the heart will often require even in valvular insufficiencies.

Many of the older physicians claimed that whiskey did no good before the fifth day of the disease. If the pulse is feeble, rapid, and irregular, we should give whiskey every three hours, and sometimes it is best to push it, ordering as much as sixteen to twenty ounces in the twenty-four hours. Champagne sometimes acts better. Sulphate of strychnine in doses of a $\frac{1}{30}$ grain every four hours for a few doses will be most useful. As a rule $\frac{1}{60}$ grain will be too small a dose for efficiency.

In old people with hard pulses and asthmatic tendency nitroglycerin, in doses of $\frac{1}{100}$ to $\frac{1}{50}$ grain, repeated every two or three hours, for several doses, seems to act well.

In certain cases in which the pulse is feeble and irregular, we may use to advantage two minims of fluid extract of digitalis or from five to ten minims of the tincture every four hours for a few doses. Digitaline may be given hypodermically in doses of $\frac{1}{100}$ to $\frac{1}{50}$ grain.

Hypodermoclysis in the flanks or under the breasts, of from eight to sixteen ounces of hot normal salt solution, is sometimes very efficacious and may be repeated. So are rectal injections of hot salt solution.

Camphor is much vaunted, but I cannot speak from experience. I have used ether subcutaneously in desperate cases without success. It is in the second stage of pneumonia that we usually need most of the stimulation, and especially directly after the crisis.

In delayed convalescence the ordinary tonics come into play.

The diet in pneumonia should not, in my opinion, be confined to milk. Animal broths, beef juice, jellies, egg nogg, custard, ice cream, whey, orangeade, lemonade, pure grape juice can all be allowed in the early stages. I believe that the patient's inclination should carry great weight.

If no signs of intestinal indigestion are present, a greater latitude may be exercised. I have had a patient with double pneumonia, who recovered, call for broiled chicken and chops, which he ate without bad results on the day of the crisis and he continued a solid diet until well.

In order not to prolong this paper unduly, I will not speak of complications, sequelæ, irregular types, nor of the special care of alcoholics, morphino-maniacs, asthmatics, nephritics, etc., in pneumonia.

I cannot too strongly deprecate the excessive interference practised in many of the ordinary cases. I have seen patients robbed of sleep, their temperatures increased, their hearts overtaxed, their respirations made more labored, and their general condition rendered miserable by pulling and hauling, examinations and baths and injections and poultices, taking oxygen and drugs, all of which seemed to me largely unnecessary.

I am greatly impressed and heartily endorse a statement by Dr. W. Gilman Thompson, in a recent paper on this subject, emphasizing "the necessity of prescribing proper intervals of rest in which the patient is free from incessant efforts at medication." This should be ordered as a specific prescription.

A restful night and a quiet day will often do more for the patient than brilliant polypharmacy and spectacular physical interference.

441 Park Avenue.

RENAL REDECAPSULATION.

By GEORGE M. EDEBOHLS M.D.,
NEW YORK.

One invariable effect of renal decapsulation as observed in numerous experiments upon animals, as well as in the few reported autopsies after operation in man, is the formation of a new capsule proper, replacing the one removed at operation. The new capsule becomes fully organized in from three weeks to three months after operation; it may be thinner or thicker, but is always more succulent and vascular than the original capsule.

The striking improvement or entire disappearance of urgent symptoms of chronic Bright's disease so frequently following renal decapsulation, and the fact that a new capsule is invariably formed and takes the place of the one removed, has no doubt suggested to many minds, as it has to my own, the possible propriety or indication of a second decapsulation or renal redecapsulation, in selected cases in which, after a more or less protracted period of improvement, the clinical symptoms return or become aggravated. A prominent surgeon whose kidneys I decapsulated for chronic Bright's disease one year ago, and who at the present writing is enjoying good health, writes me that if his symptoms should return he intends to ask me to decapsulate his kidneys a second time. It remained, however, not for a surgeon, but for a no less distinguished internist than Dr. E. G. Cutler, Visiting Physician to the Massachusetts General Hospital, to first give expression to this thought in print. Dr. Cutler (*Boston Medical and Surgical Journal*, 1903, CXLIX, 429), after detailing the autopsy in a case operated on by Elliott, in which for a time there was very great improvement in all symptoms, with a final and fatal recurrence of the latter, says: "It is obvious from this that if a patient does not continue to improve at the first operation of decapsulation, it is no more than fair to give him the benefit of a second operation."

I have recently had occasion to decapsulate a second time the kidneys of a patient upon whom I had performed renal decapsulation two years previously. As far as my knowledge goes, this is the first and thus far the only instance in which renal redecapsulation has been performed. For that reason mainly I have thought it worth while to publish the history of the case in detail.

C. L., male, twenty-six years of age, single, suffering from chronic Bright's disease, was referred to me for renal decapsulation by Dr. Junius T. Ireys, Lakeside, San Diego Co., Cal.

Family history good. Patient considered himself well until the early part of 1897. The symptoms then noticed were weakness, brick-dust sediment in urine, and one severe attack of headache and vomiting. An examination of the urine on June 13, 1897, showed the presence of chronic Bright's disease. Frequently repeated urine examinations made at various times during the past five years always showed albumin and casts. There was marked œdema of the feet for three months in 1898, only occasional and very slight œdema since. Patient is subject to migraine, but apart from this and the symptoms above noted, there were few or no indications of poor health.

Examination, April 10, 1902. Patient's muscular condition and color good, owing to almost constant out-door life in the South, from which he had just returned. Heart, arteries, and fundus of eye, normal. Slight œdema of feet. Examination of urine shows chronic nephritis with infection (Urinalysis, April 25, 1902). Bacteriological

tures, made later on from an aseptically drawn specimen of urine, showed the infecting agents to be the *Staphylococcus albus* and the *Bacterium coli commune*.

First operation, May 1, 1902, at the New York Post-Graduate Hospital. Decapsulation of both kidneys under nitrous oxide and oxygen, administered by Dr. Thomas L. Bennett.

The right kidney was found contracted to about three-fourths the normal volume, irregular in outline, deformed, and very hard. The capsule proper appeared slightly and unevenly thickened, but otherwise normal; it was readily detached from the kidney over the entire surface of the latter. The rawed kidney surface presented everywhere the typical granular appearance of advanced chronic interstitial nephritis. The left kidney was contracted to about two-thirds the normal volume; otherwise it was in the same condition as the right kidney. The capsules were completely stripped from both kidneys and cut away. Operative diagnosis: Right and left chronic interstitial nephritis, with infection. Convalescence was uneventful and both wounds healed by primary union.

Soon after operation the patient started on a tour of pleasure around the world. The last examination of urine prior to sailing, made June 23, 1902, showed no improvement over the specimen examined before operation; if anything, the renal infection appeared more active. The patient, however, felt perfectly well and had nothing especial to complain of. I did not see him again for more than a year and a half, nor was it possible during that time to obtain a specimen of urine for examination.

On January 10, 1904, the patient reappeared in New York and gave the following account of himself: For about six months following operation he appeared to be doing very well. In December, 1902, he was laid up in Japan for a week with acute suppurative pyelonephritis. A month later he passed through a similar experience in Calcutta, the second attack lasting ten days. After that the condition of his health was subject to slight fluctuations due to several minor exacerbations of the renal infection. On November 29, 1903, during a sojourn at a Southern health resort, a severe attack of acute infection, or rather of acute exacerbation of the chronic infection, developed. The attack was characterized by high fever, much headache, inflammatory swelling of the right epididymis, and the discharge of large quantities of pus with the urine. On several occasions the patient, as he expressed it, "passed three to four teaspoonfuls of pus in a solid bunch." The attack lasted for nearly a month with varying intensity. After its termination the patient, by my advice, came North for treatment of the persistent urinary infection.

Cystoscopic examination, made January 10, 1904, showed inflammation of the prostatic urethra and of the trigonum vesicæ, with puffiness and hyperæmia of the mouths of both ureters, the mucosa of the bladder elsewhere being normal. A nearly healed prostatic abscess was still discharging small quantities of pus into the urethra. Urine examinations during January and February (*vide* table) showed unmistakable renal infection. Bacteriological culture of an aseptically drawn specimen of urine demonstrated the infecting agents to be the *Staphylococcus albus* and *Bacterium coli commune*.

The urinary infection was treated by the internal exhibition of urotropin in large and cumulative doses and by vesical irrigations and deep urethral applications of a silver preparation. The cystitis and deep urethritis were soon brought under control, but the renal infection persisted. There was, however, at no time after the treatment was begun, any rise of temperature or other indication of exacerbation of the chronic infection.

Increasing anæmia and deepening uræmia were the alarming features of the case during this period. A blood examination made January 13, 1904, gave: Erythrocytes, 3,678,000; leucocytes, 8,853; hæmoglobin, 80 per cent. A second count, made February 5, 1904, yielded: Erythrocytes, 3,533,000; leucocytes, 10,113; hæmoglobin, 60 per cent. The fluctuations in the daily output of urea may be seen from the appended table of urine examinations.

After the vesical and urethral infection was removed, there appeared to be no immediate further indications for surgical treatment, and I requested my friend Prof. A. Caillè to take charge of the case. For the last two months of his life the patient was constantly under Dr. Caillè's care and observation. Early in February frightful uræmic headaches and an extensive uræmic infarction of the right lung with considerable hemorrhage developed, and Dr. Caillè advised redecapsulation of the kidneys, with a view to increasing the urea output. The advice was declined, and for nearly two months more the patient went on from bad to worse, the atrocious uræmic headaches being almost constant in character. On March 30 uræmic convulsions supervened, followed by continuous coma and great swelling and discoloration of the face. On this day, also, complete suppression of urine occurred, the bladder being repeatedly catheterized and always found empty. On March 31 the patient was in a moribund condition, permanently unconscious, and frequently in convulsions, not a drop of urine having been secreted by the kidneys for more than thirty hours. Sweating, free purging, colon flushings, and other therapeutic resources, including a venesection with the abstraction of over 500 c.c. of blood from the arm, had proved powerless to control the uræmic crisis or to start the action of the kidneys. At this stage of the case, with the end but a few hours away, I was requested by Professor Caillé to assume again charge of the case and to perform a second decapsulation of the kidneys as a final resort and forlorn hope. In view of the proven potency of renal decapsulation in relieving suppression of urine and increasing the urea output when all other measures had failed, I declared myself ready to operate upon this desperate case. The patient was brought to my private hospital, and within an hour after his arrival the operation was begun.

Second operation, March 31, 1904, under nitrous oxide and ether anæsthesia. Redecapsulation of both kidneys.

The patient was carried to the operating room unconscious, livid, and with beginning œdema of the lungs, the heart's action, however, still being fairly good. A catheter was passed and the bladder was found empty. An incision was carried on the right side through the scar of the first operation and the kidney was exposed. The fatty capsule completely covered the kidney, being adherent posteriorly to the scar of the former operation and anteriorly to the kidney. The kidney was thus indirectly and mediately anchored to the walls of the abdomen in the lumbar region. After detaching the fatty capsule the kidney was found covered by a newly formed capsule proper, not differing greatly in appearance from the capsule removed at the first operation. The new capsule was thinner and perhaps more transparent than the original capsule, which it will be recalled was slightly and unevenly thickened. It was peeled off from the entire surface of the kidney and cut away with no greater difficulty than obtained in the case of the original capsule. There was not the slightest evidence of compression

of the kidney by the new capsule. The perirenal fat was found well vascularized, though the entire operation, including the separation of the capsule from the kidney, was practically bloodless, owing possibly to the liberal venesection of the previous day. The kidney itself was found of exactly the size and volume encountered at the first operation two years previously. It presented also the same characteristic gross appearance of chronic interstitial nephritis. It was, however, decidedly less hard and more succulent to palpation than at the first operation. The left kidney was next operated upon, the description above given of the operation on the right kidney holding good also for the operation on the left urinary gland. The left kidney was found in identical condition as regards size and gross appearances with that found at the first operation; it likewise was distinctly more succulent and less fibrous than at the first operation two years before.

On completion of the operation the patient was returned to bed in about the same condition in which he came to the operating table. The uræmia remained uninfluenced, and five hours after operation the patient died in uræmic coma. The flow of urine, however,—and this is a matter of considerable practical interest—was started by the operation, although too late to be of any avail in saving life. During the last three hours of life the patient unconsciously voided into bed considerable quantities of urine, the exact amount of which could not be determined.

Urine examinations were made during the progress of the case to the number of more than thirty. The appended table contains a selection from those made by Prof. H. T. Brooks or Dr. W. G. Vincent. They show little or no practical improvement, the change for the better otherwise to be expected after renal decapsulation being neutralized by the persistent urinary infection.

Three points of interest stand out in the history of the case narrated: (1) The nullification of the usual good effects of renal decapsulation by persistent chronic infection of the genitourinary tract. Notwithstanding this it remains an interesting speculation as to what the outcome of renal redecapsulation would have been if performed two months earlier when first advised by Dr. Caillé. (2) The mediate and practically normal fixation of both kidneys as a result of simply dropping the kidneys back into their fatty beds after decapsulation. (3) The prompt effect of decapsulation in relieving complete anuria. Whitacre (*Journal of the American Medical Association*, 1903, XL, 1409-1416) has already detailed a case in which suppression of urine of eight days' standing was cured by renal decapsulation. In my own experience with renal decapsulation, I have repeatedly observed the prompt conversion of almost complete suppression of varying duration into free flow of a normal or greater than normal amount of urine as a result of operation.

Chronic Bright's Disease.—Case No. 30: C. L., male, aged twenty-six years. Weight, 60 kilograms. First decapsulation of both kidneys, May 1, 1902. Second decapsulation of both kidneys, March 31, 1904.

DATE OF URINE EXAMINATION	TOTAL URINE IN 24 HOURS	SPECIFIC GRAVITY	TOTAL SOLIDS IN 24 HOURS	UREA	ALBUMIN	RENAL CASTS, ETC.
April 25, 1902 (before operation)		1012		1.5 per cent.	30 per cent. by bulk, Heller.	Large numbers small hyaline, granular, epithelial and mixed casts. Occasional granular and fatty renal element. Large numbers isolated pus cells.
June 23, 1902.		1014		1.7 per cent.	30 per cent. by bulk, Heller.	Innumerable casts of all kinds except waxy. Occasional granular and disintegrated renal cell. Occasional isolated blood cell. Innumerable pus cells, isolated and in masses.
January 21, 1904.	2800 c.c.	1011	74.56 grams	14 grams in 24 hours	25 per cent. by bulk, Heller.	Numerous large hyaline, fine granular, epitheliated and mixed; occasional pus cast. Occasional isolated red blood cell. Innumerable isolated pus cells, often in small masses resembling fragments of pus casts. Numerous renal cells, occasionally finely fatty.
January 27, 1904.	3800 c.c.	1007	61.798 grams	19 grams in 24 hours.	30 per cent. by bulk, Heller.	Occasional very large hyaline and pus; also mixed and finely fatty. Innumerable pus cells, often in small masses. Considerable number renal elements, occasionally very granular.
February 5, 1904.	4000 c.c.	1008	74.56 grams.	16 grams in 24 hours.	33 per cent. by bulk, Heller.	Rarely a large hyaline and epithelial and pus. Numerous pus cells, isolated and in masses, resembling fragments of pus casts. Large numbers granular renal elements.
February 14, 1904.	2000 c.c.	1010	46.6 grams.	10 grams in 24 hours.	0.8 per cent	Frequent hyaline. Rather frequent coarse granular. Few epitheliated. Many isolated red cells. Numerous pus cells, singly and in masses.
February 20, 1904.	1700 c.c.	1012	47.53 grams.	13.6 grams in 24 hours.	Heavy ring.	Many hyaline. Occasional granular. Few mucous threads. Many red cells and many pus cells.
March 7, 1904.	1200 c.c.	1012	33.55 grams.	18 grams in 24 hours.	Marked ring.	Few hyaline. Rarely a fine granular. Few isolated red cells. Quite frequent pus cells, singly and in small masses.

Very little or nothing can at present be said concerning renal redecapsulation except that it will stand or fall as a therapeutic measure with renal decapsulation. Any further expression of opinion must, until the results of further experience are available, rest upon theoretical considerations only.

The main and most frequent indication for renal redecapsulation in chronic Bright's disease will probably remain that already outlined, *i.e.* when after a more or less protracted period of improvement following a first decapsulation the clinical symptoms should return or become aggravated. This indication does not embrace the transient acute exacerbations so frequently observed in the course of chronic Bright's disease, whether the kidneys have or have not been decapsulated. It applies rather to those cases of uræmia and of failure of kidney function characterized by a steady diminu-

tion in the amount of the daily output of urea, since the most striking and constant result of renal decapsulation for chronic Bright's disease is the increased elimination of urea. Suppression of urine, representing as it does the extreme degree of renal inactivity, is of course included in the just mentioned indication.

Johnson (*Annals of Surgery*, 1903, XXVII, 592-601) has found that in dogs the capsule proper of the kidney is composed of two layers, the inner and thinner of which cannot, as a rule, be separated from the kidney. I have on one occasion encountered the same condition in an operation upon a man twenty-seven years of age. The outer layer of the capsule proper was removed without any unusual difficulty, leaving a thin, translucent, filmy, inner layer still covering the kidney. All efforts to detach this inner layer from the kidney failed; wherever any portion of it was removed it brought away with it adherent particles of kidney tissue. In just such a case, a redecapsulation, say three or four months after the first operation, *might* succeed in removing the inner layer of the old capsule in one piece or layer with the new capsule.

To relieve imaginary pressure, supposed to be exercised upon a kidney by the new capsule formed after renal decapsulation, cannot be considered as an indication for renal redecapsulation. That the new capsule exercises such pressure has not, as yet, been demonstrated; it certainly did not do so in the case detailed.

Judging from the above solitary experience in the living and from an additional observation in the dead house, the removal of the new capsule presents no greater technical difficulties than the removal of the original renal capsule.

59 West Forty-ninth Street.

OPERATIVE SURGERY APPLIED TO THE SEMINAL VESICLES:

A DEMONSTRATION OF SOME NEW PRINCIPLES.*

By EUGENE FULLER, M.D.,
NEW YORK.

It is hardly to be expected that operative surgery in connection with the seminal vesicles will become as popularized as that relating to some other organs, owing in large degree to their anatomical position, which is sufficiently inaccessible to prevent existing pathological conditions from becoming recognized, except by those who have paid special attention to that particular. Up to the present time very few, even of those who are skilled in the diagnosis of seminal vesicular disease, have attempted to relieve existing conditions by a resort to operative surgery, and much of the surgery attempted has been attended by indifferent or poor results, for the reason, I take it, that most of it has related to the extirpation of the organs when the seat of advanced tuberculous disease. I am at present of the opinion that tuberculous disease in this connection should be treated therapeutically and hygienically rather than surgically. In my experimental work my aim has been to discover, first, the best operative method to expose the seminal vesicles, and, second, the appropriate surgical treatment for the different types of disease. Early in 1901 (February 10) I read before the New York County Medical Association a paper entitled "A New Operative Method to Expose the Seminal Vesicles and Prostate for Purposes of Extirpation and Drainage; a Preliminary Report." This paper was afterward published in the *Journal of the American Medical Association*, May 4, 1901. The chief features of the operative technique were the knee-breast position and the extent of the lateral incisions which allowed a free dislocation upward of the rectum. To attain the operative position I used formerly to place the patient on the abdomen with the buttocks over the raised end of a Trendelenburg table, the thighs being spread apart and flexed. As this position was somewhat hard to maintain on such a table, I have latterly found it much easier to have the patient on a flat table, kneeling with the knees flexed sharply under him and with the shoulders so depressed that the side of the face lies on the table. As the result of much further experience with this operative method, I can confidently endorse all that I claimed in its favor in my first article. I have employed it up to the present twenty-one times without a death. In fact, in no cases did any clinical symptoms of a threatening nature develop after operation. In but one case did an operative mishap occur, and that consisted of a digital perforation of the rectal wall during the course of the dissection. The perforation was closed by chromicized catgut suture and healed by first intention. In this instance the gut wall was unusually thin, and its outer fibrous layer seemed to to be but little developed, so that as the result of slight traction upon it the rent occurred.

The surgical method which I have originated for the seminal vesicles consists of seminal vesiculotomy or the exposure of the cavity of the seminal vesicle by means of a free longitudinal incision. The surgical treatments which I have introduced as a consequent to this new operation are drainage of the sac cavity, curettage, and the removel of intra-seminal vesicle neoplasms. I have not as yet happened on a case of calculus of the seminal vesicle. Another feature which, in some instances, I have combined with the operation of seminal vesiculotomy is that of freeing the organ through peripheral dissection of surrounding inflammatory adhesions, a sort of decapsulation as it were. I also feel that peri-seminal vesicle abscess can be best drained through the employment of the method of operation herein advocated. When my first paper was written I had but recently operated on my first five cases. In that paper, which was entitled a preliminary one, I simply reported what I had then done, the work being too recent to draw deductions as to its ultimate value. In the present paper the final outcome of the original cases, as well as that of numerous subsequent ones, is given, thus allowing conclusions to be drawn.

My twenty-one cases can be pathologically subdivided into five groups: Group No. 1 consisted of extremely chronic cases of seminal vesiculitis, in which the lesions consisted chiefly of sclerous tissue. Not only were the walls of the seminal vesicles sclerous, but the surrounding fibrous structures were likewise extensively involved, the result being that the cavities of the seminal vesicles were contracted and the sacs themselves bound down by adhesions. In this group of cases an intravesicle catarrh, which had formerly existed, no longer remained as an active feature, since it had become in large measure eliminated partially by the chronicity of the lesion, but chiefly by the contracting force of the sclerosis, which had, as far as possible, obliterated the sac cavities. Six of my operative cases were of this group. In four of them my results were good. In two the results were largely negative, as far as the removal of clinical symptoms were concerned.

Group II consisted of instances of seminal vesiculitis less chronic than those of Group I. In the second group the intravesicle catarrh was still a prominent feature, the sclerotic lesions in connection with the sac walls and the surrounding fibrous tissues not having developed sufficiently to cause con-

*Read before the Section on Genitourinary Surgery, New York Academy of Medicine, February 17, 1904.

traction of the sac cavities. In some of these cases, in fact, atonic distention of the sac cavities existed.

Eight of my operative cases were of this group, Three out of the eight are, however, recent cases which have just been discharged from the hospital in a very satisfactory condition, and which I expect will be perfectly cured by the operation. Of the remaining five the results have been positively good in three. Two of the cases I lost sight of too soon after operation to be positive concerning the after-result. One of these, I think, could be classed, as cured, as I expect I should have had a complaint from him had he not been satisfied. The remaining patient I left in the hospital convalescent at the termination of my annual service and then lost trace of him.

Group III consisted of cases of acute diffused peri-seminal vesicle abscess. Gonorrhœa was the infective agent in these cases. Five of my cases came under this heading. In all of them the results were particularly good.

Groups IV and V consisted of one case each. In Group IV the lesion consisted of an adenoma involving the wall of the seminal vesicle and causing an obliteration to a large degree of the sac cavity. The result attending the removal of the growth was good. In Group V the lesion was tuberculous involvement of the seminal vesicle. Removal of the sac caused only temporary relief. A sinus persisted and the patient died after several months, through extension of the tuberculous process, chiefly to the ureter and renal pelvis. This case, therefore, should be classed as an operative failure, as nothing was really gained by operation, although the operation in itself was immediately successful.

The following is a brief clinical recital of the individual cases making up the different groups:

Group I—Case I.—An Italian, about thirty years of age, referred to me by Dr. F. Tilden Brown. The chief clinical symptoms in this case were marked frequency of urination, the act being associated with great urgency and pain. There was also painful priapism, and so much pain on ejaculation as to inhibit attempts at intercourse. The urine was moderately purulent. The patient, owing to his pain, had latterly contracted the opium habit. He stated that he had been well until several years previously, at which time he had contracted gonorrhœa. During the active stage of that disease he had been treated by means of deep injections of nitrate of silver. The patient thought that this treatment had been very injurious in his case, as during its continuance the symptoms complained of had developed and had since persisted. Before coming under my observation the patient had been in numerous hospitals, and had submitted to three major surgical operations without any relief whatsoever. His bladder had been opened twice through the perineum and once suprapubically, in the vain hope of thereby removing the cause of his trouble. On examination I found a dense sclerosis not only of both seminal vesicles but also of the surrounding tissues. I operated upon him by my method, freely incising and draining both seminal vesicles. I kept this patient under observation for a year and a half. At his last report his condition was highly satisfactory. He urinated without pain about once in four hours. He was sexually vigorous, and the act itself was natural and so gratifying that he was at the time indulging somewhat excessively. The rectal feel showed an absence of the former sclerosis. In this case the improvement was not apparently sufficient to give me great hopes of an ultimate recovery for six months after the operation. I broke up his opium habit when in the hospital, and I attribute some of the apparent slowness in arriving at the end result in this instance to the after-effects of that habit.

Case II.—A man about forty years of age, whose chief clinical symptom was perineal pain, increased on sitting, which he had had nearly constantly for several years. His sexual function was almost nil. The bladder had formerly been excitable, but at present those symptoms had disappeared. Had had gonorrhœa on several occasions. The only lesion discoverable in this instance was a fair degree of sclerosis in connection with the seminal vesicles. I operated on him, opening both sacs longitudinally. His painful symptoms were promptly relieved by the operation. I last heard of him about six months after the operation; he then considered himself well.

Case III.—A man of about thirty-eight, whose complaint was impotency. He was a very phlegmatic individual and complained of no pain or other functional disturbance. Had had gonorrhœa several times in earlier years. In his case the sclerosis was very marked. I operated, incising both sacs very freely. I last saw him about four months after the operation. To the rectal feel the sclerosis had in great measure disappeared and the patient was satisfied with his sexual status. The result in this instance, owing to the extent of the sclerosis, was more prompt than I had anticipated.

Case IV.—Man fifty years old, whose chief symptom was sexual neurasthenia combined with marked melancholy. His mental symptoms were so marked as to unfit him for all business and to make one solicitous lest actual suicidal tendencies might not develop. His sexual function was crippled. His lesion consisted of a marked sclerosis, chiefly in connection with the right seminal vesicle. I operated, splitting open the affected sac very freely, the other to a less extent. It is now a year and a half since the operation. The sclerosis disappeared promptly. The sexual function did not become at all satisfactory for eight months after the operation, and during that time the patient, remained apprehensive lest the operation would prove a failure, and improved but little mentally. Since then, however, there has been a gradual and progressive improvement both sexually and mentally. For the last few months he has returned to business. His sexual function is now satisfactory and his long period of convalescence is at an end. It is well to consider the age of this patient, fifty years. Had he been younger one could reasonably have expected a shorter period for convalescence.

Case V.—A man thirty-five years old. His chief symptom was sexual neurasthenia and an inability to focus his mind sufficiently to carry on his business. His sexual function had to a large extent disappeared. He had a fair degree of sclerosis in connection with both seminal vesicles. It was in this case that the perforation of the rectal wall occurred during the performance of the operation. Owing to this accident, I did not lay open the seminal vesicles by longitudinal incisions as freely as had been my custom, being fearful of an infection of the part in case the bowel wound should not heal by first intention. In this case the patient experienced much temporary relief, but at the end of a year he reported, still complaining, and an examination showed the persistence of some sclerosis.

Case VI.—Man thirty-five years old, a periodical masturbator. Although for considerable intervals he would be able to control himself, yet at times, as the result of some incident tending to excite him, he would lose that control and then for months he

would masturbate excessively. He was of a very shy disposition. Had never had sexual intercourse and had never even made such an attempt, being apparently too diffident to approach the opposite sex. He had a peculiar hesitating manner when questioned. There was considerable insanity in his family. The only child beside himself was, from his description, apparently wrong mentally. In his case there was a marked sclerosis in connection with the seminal vesicles. I treated him for some time, stripping the seminal vesicles, but did him no good. He left me to try hypnotic treatment. That doing him no good he returned. My opinion at that time regarding this patient was that the primary trouble was mental and that the masturbation had caused the lesion in connection with the seminal vesicles. That being the case, an operation on the seminal vesicles, even though it removed the lesion, would do no good. I felt that there was a chance that the sexual lesion was the primary cause and that his mental symptoms were the result, which supposition being correct, the removal of the lesion would affect a cure. The patient being fully appraised of this reasoning elected to be operated upon. The operation was performed and the result as regards the sclerosis was good. The patient has, however, experienced no relief.

Group II—Case I.—Man thirty-six years of age. His clinical symptoms consisting of an intermittent urethral discharge, sexual disability and neurasthenic disturbances, which unfitted him for work. His lesion consisted of atonic distension of both seminal vesicles, a highly catarrhal state of the contents of the sacs and some sclerosis of the sac walls and surrounding tissues. This was my first operative case. The seminal vesicles were not incised as freely as in my subsequent cases. The result was encouraging and I expect good, although the patient was left with symptoms due to hemorrhoids, which served to mark to some degree the sexual result. In this case in making my dissection I kept too near the rectal sphincter and so to a certain extent disturbed the function of that part. The usual operation for hemorrhoids was later indicated in this instance. I lost sight of this patient soon after he left the hospital.

Case II.—A man thirty years of age. His sexual lesions and symptoms corresponded to those of case I. The lesions, however, were less aggravated. I thoroughly drained the seminal vesicles. The man left the hospital in a satisfactory condition and reported six months after, stating that he was well.

Case III.—A man thirty-five years old, impotent and extremely neurasthenic. Had also much perineal and testicular pain. There was a fair degree of intra-seminal vesicle catarrh and much sclerosis. The sacs were freely incised, gently curetted and drained. The operative result was highly satisfactory in ridding the patient of his lesions. He disappeared from view one month after leaving the hospital, feeling then improved. I expect the result in this instance is good.

Case IV.—A man twenty-eight years old. Chief complaint a persisting discharge. His lesions were very similar to those in Case II. Seminal vesicles freely incised and drained. Reported eight months after operation, stating that he was well. His sexual function was satisfactory.

Case V.—A man of about thirty years of age. He complained of a relapsing discharge following intercourse, and some frequency of urination, the act being followed by pain. His sexual strength was weak and the act largely devoid of normal sensation. In this case there was considerable sclerosis in connection with the seminal vesicles and some intra-seminal vesicle catarrh. Both sacs were freely incised, curetted, and drained. This case was lost sight of about four months after operation. His condition was then satisfactory. His clinical symptoms had disappeared and his sexual function was satisfactory.

Case VI.—A man thirty-five years old. Complained of marked sexual weakness, pain on ejaculation, perineal pain and some uretheral discharge. Had marked intra-seminal vesicle catarrh, considerable atonic distention of the sacs and some sclerosis. Last saw him a few weeks ago, shortly after he had left the hospital. I see no reason to doubt a good ultimate result in this case.

Case VII.—Man about thirty-two years old. His chief complaint was a persisting uretheral discharge, some urinary frequency and a moderate degree of sexual derangement. The patient is of a phlegmatic disposition and consequently his reflex nervous symptoms were not apparently marked. This man is now ready to be discharged from the hospital. He has no uretheral discharge and is satisfied with the operation.

Case VIII.—Man, twenty-five years old. Complained of pain in the right iliac region, which became marked on exertion and was aggravated also by any sexual excitement. A constipated state of the bowels caused him much pain in that region. He was unnaturally excitable sexually. When the iliac pain was pronounced his urination was frequent and painful. His urine at times was purulent. He had suffered in this manner for a year and a half following gonorrhœa. Rectal feel showed the right seminal vesicle to be very extensively involved. It was greatly tumefied, and tender (the tumefaction involving the surrounding tissues). On digital rectal pressure much catarrhal material was expressed. I incised the diseased sac very freely and curretted its interior. My patient is now ready to be discharged from the hospital. He is wholly relieved of his pain and is very happy. To the rectal feel rapid resolution is going on at the seat of operation.

In all the cases of Group II just considered, gonorrhœa was the primary cause for the existing lesions.

Group III—Case I.—Man twenty-two years old, developed retention of urine at the termination of his fourth week of gonorrhœa. Associated with his retention and the usual attendant bladder symptoms were great deep perineal pain and tenderness, rectal tenesmus and much pain on defecation. The finger in the rectum detected a large tumefaction bulging into the rectal space. This tumefaction involved the prostatic capsule, the seminal vesicles and the tissues about the seminal vesicles. I operated according to my method and drained a peri-seminal vesicle abscess in an early stage of development. The seminal vesicles were not in this instance opened. In forty-eight hours after the operation the power to urinate returned. The patient left the hospital well in his fourth week.

Case II.—Man twenty-five years old. Contracted gonorrhœa about five weeks previously. Shortly following strong injections applied to the deep urethra, symptoms of rectal and vesical tenesmus developed, together with much perineal pain. The act of urination was frequent and difficult. Rectal feel showed much tumefaction and great tenderness in the post-prostatic region. I opened this region in my usual way. No actual pus formation was discovered, the operation having evidently just anticipated such an occurrence. The region was drained, the result being a rapid disappearance of the tumefaction, together with the subjective symptoms. After a brief interval the patient was discharged from the hospital well.

Case III.—Man thirty years old. Gonorrhœa con-

tracted one month previously. When seen by me for the first time in consultation had all the general symptoms of severe sepsis. He had his first retention three days before. He was then suffering extreme localized deep perineal pain. The following day his pain suddenly became more diffused. He had a severe chill and the power to urinate, though with difficulty, returned. Soon after this, surface tenderness on the buttocks began to develop. Examination showed the post-prostatic region greatly tumefied. A brawny induration also involved the entire ischiorectal space. The surface tissues of the buttocks were porky and tender to the feel. It was evident to me that a peri-seminal vesicle abscess had first formed, causing retention. As this abscess burst out of its space and into the ischiorectal region, the pressure about the neck of the bladder was temporarily sufficiently relieved so that the power to urinate returned. I advised prompt and free drainage of the entire region if death from sepsis was to be averted. There was delay in accepting my advice, so that the operation did not occur till forty-eight hours later. General sepsis had then become so pronounced as to make the condition of the patient desperate. The operation was, however, wholly successful. The patient entirely recovered, although it took him considerable time to regain his stamina. I feel that no other operation would have drained the involved area sufficiently to have saved the life of this patient.

Case IV.—Man thirty-five years old. Some months previously had had gonorrhœa, but had thought himself well. About a week before coming under observation a pain had developed in the pelvic region, the location of which was rather indefinite. A few days later he found that he urinated with increasing difficulty. He went to a hospital dispensary, was examined for stricture, and as none was found he was dismissed, being told that nothing was really wrong and that his supposed trouble was imaginary. The day following the search for stricture, he developed retention, and then came under my observation at the Post-Graduate Hospital. The pelvic pain had at that time increased slightly. As the result of rectal exploration, a moderate degree of œdema was detected in the post-prostatic region. The urine was clear and his reflexes were normal. Thinking in this obscure case that an abscess was forming in the post-prostatic region, I performed my operation, and on entering that space a small amount of pus, less than a drachm, was liberated. Drainage was instigated. In less than twenty-four hours the patient was urinating freely. He left the hospital well after a rapid convalescence.

Case V.—Man, twenty-one; retention in the fourth week of his first gonorrhœa. He had great pain in the deep perineal region, and the feel per rectum showed marked tumefaction of the prostatic and post-prostatic region. I operated as usual and liberated a collection of pus from a peri-seminal vesicle abscess. The patient recovered rapidly, though in this instance some urine escaped for several days along the tract of the incision, showing that the abscess when opened was about to discharge itself into the bladder.

Group IV—Case I.—Man, fifty-five years old. His clinical symptoms were pain in the right testicle and a pain along the right side of the penis. These pains were largely paroxysmal and when at their maximum were severe. Urination was frequent and the desire urgent. Exercise increased his discomfort. There was no obstruction to the flow of the urine. He did not indulge in sexual intercourse, but felt that an attempt in that direction would aggravate his symptoms. His trouble began suddenly three years previously with pain in the right testicle and had persisted. Had had gonorrhœa twenty-five years ago, otherwise had had no venereal history. Examination per rectum showed a very firm mass the size of a marble in the right seminal vesicle. I performed my usual operation, split open the seminal vesicle longitudinally and removed the neoplasm by means of a sharp curette. The growth proved to be an adenoma, though the pathologist at the time was fearful lest it might not also have qualities of carcinoma. The patient was very stout, and it was consequently difficult to keep the drainage tubes in place. Owing to insufficient drainage, the tract of the wound had to be divulsed and the part redrained several weeks after the first operation. The patient then, however, recovered completely and disappeared from observation. I have under observation another case, apparently similar to this one, on which I have soon to operate.

Group V—Case I.—Man, forty-five years of age. His chief symptoms were urinary frequency and distress, some pyrexia and much deep perineal pain. The urine was somewhat purulent and tubercle bacilli were demonstrated. Rectal feel showed marked tumefaction of the right seminal vesicle, together with an inflammatory involvement of the surrounding tissues. I determined in this instance to remove the diseased sac. I employed my usual method and accomplished the removal; although the surrounding adhesions were so dense as to make the operation somewhat difficult. The immediate effects of the operation were good, the distressing symptoms being ameliorated. The tract of the wound, however, never closed, a sinus persisting. At the end of six weeks further pyrexia manifested itself, and there was also a redevelopment of symptoms, such as existed previous to the operation. It was then found that the tuberculous process had invaded the remaining seminal vesicle. After a time evidences of renal tuberculosis appeared. Within five months after the operation, the patient having gradually failed, died. The post-mortem examination showed marked tuberculous involvement of the renal pelvis and its connecting ureter, a developed pulmonary tuberculosis and minor lesions of a like nature elsewhere. The operation in this instance did not stay the progress of the disease. In fact, I expect its tax on the patient's vitality, owing in great measure to the necessitated confinement to bed and the local disturbance to the tissues consequent on its performance, were greater aids to the propagation of the systemic tuberculosis than the undisturbed harboring of the originally infected seminal vesicle would have been.

The foregoing results are sufficiently numerous and good, not only to justify me in no longer calling the work experimental, as I did in my first article, but to warrant me in advocating such treatment in many cases of Group I, in some instances of Group II, and in all cases of Groups III and IV. In Group V nothing was apparently gained by the surgical interference. I do not feel that the operative surgery that I am now advocating is destined to or should supplant my method of stripping the seminal vesicles as a routine mode of treatment for the first two groups of cases. If an individual is so situated as to be able to present himself regularly for office treatment as long as may be necessary and be free from tuberculous taint, he can in most instances of Group II, and in many of those of Group I, be cured, by means of digital rectal manipulation, or at least so far benefited as to relieve him of subjective symptoms. In all cases of these two groups wherein the stripping treatment has failed I would advise the operative treatment just de-

scribed. Many individuals with such lesions, owing to the remoteness of abode, exactions of business or other cause, cannot submit themselves to a regular and prolonged attendance at a surgeon's office. For them an operation is the only effective method of treatment available.

For the liberation of pus in this deep region the operation under consideration is better than the three other surgical methods in vogue, which are (1) perineal section, with a median incision through the trigonum; (2) incision through the rectal wall, and (3) perineal incision through the prostate. Although topics of much interest, it is beyond the scope of this paper to discuss the surgical disadvantages of those three drainage operations as compared with the one I advocate. The advantage of the operation for the removal of a tumor of the part is self-evident.

Some, of course, will take exception to the stand I take against the removal of tuberculous seminal vesicles. To such I will say that I am ready to change my opinion as soon as they can show operative results sufficiently at variance with those generally on record to make it evident to me that I am at present in error in this particular.

253 Lexington Avenue.

WHO IS UNDERFED?*

By HEINRICH STERN, M.D.,
NEW YORK.

The impression prevails oftentimes that the lean or apparently emaciated person must of necessity be underfed. This, however, is erroneous, for the lean person or one who—within certain limits—is losing in body-weight and circumference need not be at all underfed. In the lean, as long as the egress of material is made good by an ingress of assimilable substances, there does not prevail a condition of subalimentation. Furthermore, in the obese, the reduction of excessive weight by diminution of diet does by no means imply that the individual is being underfed. The excessive weight, especially if the case is one of metabolic obesity, merely demonstrates that the individual had been overfed. Hence, a proper dietary for the reduction of metabolic obesity is primarily devised not for the promotion of a state of underfeeding but for the prevention of further adipose accumulation; the removal of the surplus fat already deposited should be entirely left to artificially induced or accelerated oxidation processes. While the lean person, in metabolic equilibrium, is never in a state of subalimentation, we can invariably demonstrate a more or less pronounced loss of body albumin in the real underfed.

The appearance of the lean, it is true, may not always conform to our æsthetic sense, he may be easily effected by heat and cold and atmospheric changes in general, he may also be possessed of an irritable nature, but notwithstanding these apparent drawbacks and deficiencies, he may not only be hale and sound but may frequently display a degree of endurance and energy, not often met with in the overnourished individual.

As a matter of fact, the dietary standards at present in vogue, especially in the cities, seem to be entirely too large. This is no news to the experienced clinician. Chittenden† has again touched experimentally upon this question. He relates an experiment with a man who, on the average, consumed 44.9 grams of protein during the twenty-four hours; the entire diet was valued at 1,606 calories. The individual was in practical nitrogen equilibrium: 6.90 grams nitrogen were in the mean excreted by the urine and fæces and 7.19 grams ingested during the twenty-four hours. The diet was very plain. Particular attention was paid to thorough mastication. The food was well digested. When we remember that the healthy adult excretes by the urine alone about 100 grams of nitrogen during one week, we understand that the nitrogenous part of the nutriment of this subject amounted not quite to one-half of that of an average adult person. Still, his body albumin remained intact and he continued in good health.‡

Hirschfeld§ relates the well-authenticated case of a lady, thirty-four years old, 1.55 m. high and weighing 90 kilo., who in the course of six years had even gained 30 kilo. while subsisting on a diet, the nutritive value of which amounted to not more than from 1,600 to 1,650 calories per day. The same author cites another case of a woman, forty-five years of age, 1.49 m. high and weighing 59 kilo., who in spite of moderate labor and a nourishment fluctuating between 1,380 and 1,570 calories, kept herself in metabolic equilibrium.

I have seen a number of instances in which practically the same facts obtained. My clinical observations, naturally, were made in individuals either of under or overweight. I have not met with a case in which marked increase of body substance had resulted from as low a nutriment as 18 calories for each kilo. of total body-weight. I have, however, come across a number of instances in which individuals already obese, or such having undergone treatment for corpulency or, finally, such who, while of underweight according to accepted standards performed considerable bodily labor, have retained their absolute weight as well as their specific corporeal density, when under a diet of approximately 20 calories, and in some instances even of less than 15 calories for each kilo. of total body-weight.¶

That much we may say with certainty, that we could materially economize in nutrition without interfering with the physiological processes in the organism in the slightest degree. We are even justified in going a step further by asserting that *the animal functions, the tonicity of the structures and organs*, in short *the normal intrasystemic equilibrium, are the better maintained, the more the sum of ingested assimilable nutrients is limited to the amount absolutely necessary to keep the body in metabolic balance.* A diet valued at from 35 to 50 calories for each kilo. of body weight in twenty-four hours, the usual standard of to-day, seems entirely too large even in the case that the individual performs continuous and hard labor. A diet of such high caloric value may probably be useful in some phases of certain types of malnutrition; in the normal person, however, it tends to excessive adiposity and all its untoward consequences.

*A paper read before the Academy of Medicine, April 9, 1904.

†Chittenden, *Popular Science Monthly*, No. 2, 1903.

‡The values selected for comparison by the observer represent the total and not the digestible nutrients as such.

§Hirschfeld, Über den Nahrungsbedarf der Fettleibigen, *Berliner Klinik*, April, 1899.

¶Of course, the very low amount of food, 15 calories and less per kilo. of body-weight, was met with in people with pronounced metabolic obesity in whom the surplus fat, which needs no special consideration in alimentation, was concluded in the total calculation. For instance, a man thirty years old, 1.71 m. (5′ 7″) in height, weighs 100 kilo. His weight, including the physiological amounts of fatty substances, should not exceed 70 kilo. (154 pounds). Partaking of a diet valued at 15 calories for each kilo. of absolute body weight, he introduces a total of 1,500 calories. However, as the surplus fat requires no supply of ingested material, the total amount of the latter is practically carried to the 70 kilo. of physiological body substance, which is in the ratio of 21.4 calories to each kilo.

Moreover, we should know whether by the caloric value of the food is meant the total or the assimilable nutrients it exhibits. In the first case, the amount of calories per kilo. and day must, of course, be higher than when assimilable material only is ingested. The elaboration itself of assimilable nutrients from the ingesta demands a certain amount of energy; coarse food is but in part utilized, a goodly amount of its nutrient elements are either not elaborated at all or undergo incomplete conversion only. The coarser the food, therefore, the more must be employed of it to derive therefrom the necessary calories. Working people as a rule can but afford the coarser forms of foodstuff; at any rate, these comprise a considerable portion, if not the bulk, of their diet. This is to a greater extent the case in other countries, as for instance in Germany, where Rubner and his followers have developed the caloric theory as it pertains to foodstuffs, and which we in the United States have accepted *in toto*. Apart from the fact that even a coarser food representing from 35 to 50 calories per day and kilo. of body-weight will yield more assimilable nutrients than demanded by the normal organisms, we must recall that the majority of the inhabitants of this country are subsisting on rather readily digestible and assimilable forms of food.

A considerable number of personal observations have demonstrated to me that the normal food demand of the adult male individual engaged in manual labor for from eight to ten hours daily, in the rarest of instances exceeds 35 calories of the coarser foodstuffs per day and kilo. of body-weight. Contrary to prevailing impressions, I found the caloric demand of the female organism, similarly occupied, not more than about two calories lower on the average. This small difference in the kilogram-caloric demands of both sexes may have been partly accidental—there may not be any difference whatsoever if the observations are extended over a larger number of individuals, or if they are made in closed institutions—or it may be due to the somewhat more trying work of the male laborers who had been under my observation.

Again, if the ingesta are of a more assimilable type—that is, if less digestive energy is evolved for the elaboration and conversion of their nutritive elements and if they leave no or little residuary substances to be excreted by the fæces, I found that from 20 to 30 per cent. less calories are required to keep the individual in metabolic equilibrium. Experience, indeed, has shown to me that loss of body albumin may be prevented by a diet of assimilable nutrients much lower in caloric value than deemed necessary by the German investigators.†

We may accept it as a fact that any normal individual may thrive well on from 30 to 35 of total ingested calories and on from 23 to 28 of assimilable calories per day and kilo. of body-weight. Viewed in this light, many cases of supposed underalimentation are not such at all, for underfed in its real meaning is synonymous with a state of malnutrition. Accordingly, an underfed adult person, in the face of assimilable material to the value of from 23 to 28 calories per day and kilo. of body-weight, is one in whose economy a portion of the ingested substances is utilized perversely, or to a lesser degree than normally, one by whose total excreta more nitrogenous material is carried from the organism in one week than has been introduced to it during the same period,‡ and in whom the loss of absolute body-weight is always accompanied by decline of strength, vital energy and resistance and occasionally also by diminution of corporeal density.

A diet of aforementioned caloric value is far above the starvation limit. What we need in this country is a thorough and rational readjustment of dietary standards. We know how to feed a horse to develop its best qualities, what to feed to cows to obtain the most and best milk, what and how much food to give to our athletes in training, but we do not know on what, or rather on how much nutriment we should subsist in order to attain the possible highest qualifications for our daily vocation.

It is self-evident that a diet just sufficient to keep an adult individual in metabolic balance, does not meet the requirements of the very young and adolescent. Growing organisms need excess of food at all times to facilitate the deposition of physiological amounts and admixtures of body albumin and fat. This comparatively larger amount of food, however, should not exceed certain well-defined limits. It must not be too one-sided, so that one class of nutritive elements, at the expense of others, preponderates for any length of time, and it must conform, to some degree at least, with the amount of physical work executed by the growing organism.

Before attempting overfeeding as a therapeutic measure, the physician should convince himself whether the subject is really in a condition of underalimentation. He should ascertain:

1. Whether the individual is of underweight (see table).

2. Whether the underweight is due to ingestion of food, too small to maintain the metabolic balance.

3. Whether excessive exertion or labor stands at the foundation of the underweight.

4. Whether the individual is affected with a congenital anomaly or with any other disease or disorder.

5. Whether such anomaly, disease or disorder stands in causative relationship to the condition of subalimentation and underweight.

AUTHOR'S TABLE DENOTING MEAN HEIGHT AND WEIGHT OF BOTH SEXES IN THE DIFFERENT AGES OF LIFE IN THE UNITED STATES.

Age.	MEN.				WOMEN.

†Heinrich Stern, On the Treatment of Obesity, *Journal of the American Medical Association*, February 15, 1902. The same, The Obesity of Adolescence, *New York Medical Journal*, March 20, 1902.

‡The frequent fluctuations in the amount of excrementitious substances, mainly of those containing nitrogen from day to day, make it advisable to extend the metabolic observations over a longer period than the customary twenty-four hours; the fluctuations from week to week reflect with greater certainty the metabolic conditions in the organism than those from day to day.

The weight of an individual may be called subnormal if it is more than 15 per cent. below the weight corresponding to the height and age as shown by the table on page 812 which I have compiled from various statistics and from numerous personal investigations. Such a person, however, cannot be classified as underfed as long as he remains in nitrogen balance and does not decline in absolute as well as in specific weight. Moreover, the amount of ingested material in the pertaining instances may not be at all small. On the contrary, a person may consume considerable quantities of food and yet remain lean and appear ill-nourished. Again, the excreted nitrogen need not surpass the intake, it may just about equal it—that is, enough nutritive elements may be assimilated and utilized in anabolism to prevent plasmolysis or to replace lost body albumin. Judging by the dietary standard, such an individual is not underfed. *Underweight and underfed, accordingly, are* NOT *synonymous conceptions.*

Furthermore, it must be determined whether underweight is the consequence of too accelerated oxidation processes in the organism as effected by continued undue exertion. If this is the case, the amount of work must be so regulated that the nutriment conforming to physiological needs, suffices to prevent loss of body substance. The opposite—that is, greatly increased ingestion of food—must not be attempted, or, at least should be employed for limited periods only, as the great demand upon the digestive glands and the forced augmentation of cellular metabolism may sooner or later be followed by various organic insufficiencies and by systemic decline.

A very important and in the great majority of instances the only factor underlying the underweight is an inherited or congenital anomaly, or an acquired disease or disorder of some kind. The leanness and apparent emaciation of the majority of those affected thereby is due to an anomalous condition of or in one or more of the organs of digestion and assimilation, or to anomalous action of certain cellular structures, or to extensive structural changes in other organs or to perverted, accelerated, or inadequate function of the enzymes and secretions participating in systemic anabolism or catabolism. Underweight, in the absence of tangible disease and in the face of superabundant ingesta and moderate bodily exertion, must depend upon an abnormal structural or functional condition. An individual belonging to this category may not be underfed in the strict sense of the term—he may be in nitrogen balance and in apparent good health, the organism having adapted itself to the peculiar metabolism—but any unusual exertion or any intercurrent disorder may readily bring about a real condition of subalimentation.

In the real underfed there is always a traceable disease or disorder which directly or immediately prevents normal ingestion or complete utilization of foodstuffs, giving rise thereby to bodily decline. These are the cases which are especially benefited by treatment. However, overfeeding alone will hardly ever suffice in these instances. Before it is instituted, the organism must be prepared to receive properly, elaborate, and assimilate the nutrient material.

Viewed from the standpoint outlined in the foregoing, a person in perfect metabolic equilibrium and in the possession of the strength and endurance necessary for the fulfilment of his vocation, notwithstanding an eventual small body-weight is not underfed and does not require overfeeding. Treatment for the purpose of raising the absolute weight of an individual and thereby his vigor and resistance is primarily indicated in such conditions only in which the organism is in actual decline and in which a recognizable disease appears to stand at its foundation.

TETANUS TREATED BY INTRANEURAL INJECTION OF ANTITOXIN.

By JOHN ROGERS, Jr., M.D.,
NEW YORK.
SURGEON TO GOVERNEUR HOSPITAL, ASSISTANT SURGEON TO ST. FRANCIS' HOSPITAL.

It has been known for some time that the tetanus toxin exerts its effects entirely upon the cells of the central nervous system, particularly those of the spinal cord. In 1902 (Marie and Morax, *Annales de l'Institut Pasteur*, Vol. XVI, p. 818, 1902) some interesting experiments were published showing that the absorption of the poison depended upon the integrity of the axis cylinders of the nerves, and that it was taken up by the muscle end apparatus of these nerves and flowed through the axis cylinders centripetally or toward the center. A more recent paper (Meyer and Ransom, *Archiv für Experiment. Pathol. u. Pharmacol.*, 1903, Vol. 49, p. 369) seems to confirm and amplify these facts and propose a more hopeful therapy than any heretofore suggested. Apparently the toxin can ordinarily only reach the spinal ganglia through the motor nerves—and it enters these only through the terminal muscle-end apparatus. Even when the toxin is placed directly beneath the dura of the spinal cord, provided the integrity of the nervous tissue is not disturbed, its course to the cells in the cord is through the lymph and then the blood, and so to the periphery and thence up the nerves before any of the usual results occur.

To traverse a nerve from its end to its origin in the cord takes several days, and the longer the nerve the more time required before the symptoms of poisoning appear. Injection of the toxin directly into the substance of the cord causes tetanus within a few hours. Furthermore the toxin seems incapable of travelling in any but the motor nerves, and in these only centripetally. It cannot diffuse from above downward. The antitoxin pursues exactly the same course, and an effective means of using it at once suggests itself. Inject it into the nerves, which the toxin must traverse to reach the cord, and also into the cord itself. Experimentally this seems to succeed perfectly, and at the same time the failures in the use of antitoxin are made plain. When the microorganisms can be demonstrated within a short time of the receipt of the injury and the antitoxin can be given subcutaneously or intravenously before the appearance of any symptoms, success with this treatment has been reasonably certain. It takes some time for the bacilli to develop and produce their poison, and some days for this poison to traverse the nerves from the periphery to the center; the antitoxin enters the nerves ahead of or with the toxin and prevents the intoxication. But a culture from every wound is more or less impracticable. During the week following the last fourth of July, for example, the house staff of Gouverneur Hospital very kindly took for me some thirty to forty cultures from as many suspicious wounds which came to the dispensary for treatment with the object of giving protective inoculations. But in not one of these was the tetanus bacillus found, and the experiment was abandoned.

After the development of symptoms, subcutaneous, intravenous, or intracerebral inoculations with antitoxin are manifestly useless. If given intracerebrally it cannot diffuse downward into the spinal centers; in other words, it cannot reach the region of vital importance; and if given intrave-

nously or subcutaneously it can only follow the toxin up to the cord, as it must first be carried to the peripheral muscle-end apparatus. It may, and theoretically, at least, certainly should, help a chronic or subacute case, but if there is any severe infection not much could be expected. For a patient already giving symptoms it seems reasonable, therefore, in the light of this knowledge, to expose the nerves of the part in which the primary infection lies as near the cord as possible and to inject the antitoxin into the substance of each nerve. This will prevent the absorption of more toxin. Then the antitoxin should be injected into the spinal cord low down, or in several places, to "head off," so to speak, the toxin which must have entered the blood and so be carried to all the other motor nerve-endings in the body. A single high injection in the cervical cord would be not only dangerous, but useless, as the toxin apparently cannot diffuse in a centrifugal direction, and the antitoxin seems to follow the same law. As the experiments show that the most minute abrasion of nervous tissue is sufficient for the entrance of the toxin, the usual lumbar puncture offers a reasonably safe and certain method of obtaining the desired result. The point of a needle introduced dorsally in the third or fourth lumbar interspace should scratch one or more of the nerves in the cauda equina, and so afford the necessary means of ingress for the antitoxin. At the close of the article by Meyer and Ransom a case is reported without details, however, which seems to have recovered by following this method of treatment. So far as I know there is no other, and the following history is contributed as a suggestion for more extended trials in this condition, which has generally been regarded as more or less hopeless.

J. H., a boy of twelve years, on March 17, 1904, received a shot wound in the lower part of the left palm between the middle and ring fingers from a toy pistol. The wound was treated within a few hours at a dispensary by the application of a wet dressing. Four days later his family physician was called in, as there was some pain, and this doctor removed some portions of wadding and other foreign matter from the rather deep lacerated and punctured wound. It was then thoroughly cleaned and packed, and with a change of dressings every other day seemed to proceed favorably.

Nothing was noted until April 1, when his mother observed that he seemed to eat with a little difficulty. On Saturday, April 2, this was more noticeable, and during this and the following morning she says he walked stiffly. On Sunday, April 3, the stiffness increased so that the boy had to lie down, and in the afternoon he became rigid and complained bitterly of the cramps in his back and legs. I found him that evening with marked trismus, barely able to separate the teeth, and in the typical opisthotonous position with all the muscles in tonic contraction. The opisthotonous was so marked that his family had difficulty in getting him to the hospital in a cab.

Under ether anæsthesia (11 P.M., April 3) the lower end of the brachial plexus was exposed in the axilla where it surrounds the artery and the inner and outer heads of the median nerve, the trunks of the ulna, musculo spiral, muscula cutænous and circumflex nerves identified without much difficulty. Into the center of each of these the needle of an ordinary aspirating syringe was plunged and some 5 to 10 minims of the New York City Health Board's antitoxin injected. This caused the nerves to swell to about the size of the little finger. The axillary wound was then closed immediately and dressed aseptically, the patient turned over and the needle introduced dorsally between the third and fourth lumbar vertebræ; after allowing about 3ss of cerebrospinal fluid to escape, the needle was partially withdrawn and reinserted two or three times in an attempt to scratch some of the nerves in the cauda equina, and a dose of 130 minims of the antitoxin was then injected subdurally. No change in pulse or respiration occurred.

The rather deep granulating wound in the hand was then energetically scraped out, and after arrest of the bleeding, tincture of iodine was swabbed over the raw surface and a wet bichloride dressing applied.

The following morning, on Monday, April 4, the nurse reported that he had slept quietly, and I found that the rigidity of the legs had almost disappeared. The trismus was much improved and the extensors in the back less stiff. There was no paralysis whatsoever in the affected arm. The change for the better in the whole picture was very marked, but the signs of tetanus were still unmistakable. He was, therefore, again anæsthetized in the morning of April 4, the lower end of the axillary wound opened and about 5 minims of antitoxin injected into the substance of the nerve, probably the median, which lay in sight. Some 60 minims of antitoxin in addition were also injected into the loose cellular tissue around the nerves and under the sutured incisions of the previous night. A second lumbar puncture was then made and 160 minims of antitoxin injected subdurally. The wound in the hand was again scraped and a culture taken and the raw surface swabbed as before with tincture of iodine. The culture was forgotten the previous night, and the one at the second dressing unfortunately showed no organisms which the bacteriologist could positively identify as tetanus, although a gas-forming bacillus was present with the streptococcus and staphylococcus. The lack of this positive proof, however, I do not consider as in any way negativing the correctness of the clinical diagnosis.

In addition to the antitoxin he was given, by rectal injection, four doses each, consisting of gr. xv of chloral hydrate and gr. xxx of bromide of sodium, on April 4.

There was no reaction from the antitoxin injections, except that the temperature this day (Monday, April 4) reached 102° F. On Tuesday nearly all the rigidity had disappeared, and the boy was much edified because he could wiggle his "toes" for the first time since the previous Saturday. There was still some stiffness about the back and the masseters —he could chew only with considerable effort, and he could only sit up with assistance, but he could roll around in bed and flex the neck, arms, and legs with perfect freedom. The chief complaint was the extreme weakness, which disappeared very gradually. The wounds healed with very little suppuration; he sat up for the first time on the 14th, and began to walk on the 18th, and left the hospital entirely well on the 23d of April.

This case might be criticised as one which was subacute or chronic from the outset and liable to recovery with any treatment, and hence no conclusions should be drawn as to the efficacy of intraneural and intraspinal injections of antitoxin. But there are cases like this one above described, which can be called "delayed acute," and which in my experience are almost, if not quite, as fatal as the ordinary acute forms of the infection. The theory, or rather the positive proof, of the way in which the poison reaches the spinal centers through the muscle-end apparatus of the motor nerves, or through a wound of the motor nerves, helps to explain how a case can be both delayed and acute. The poison begins its journey to the center, as apparently in the

above case, at the very end of one or more of the motor nerves of an extremity, and so has a long course to travel, and experimentally, at any rate, it does this slowly. A chronic case, or one which generally recovers, probably has the same explanation, with the addition that there are very few bacilli.

However, the success in this instance may be regarded, and the change in two days from a condition of tonic spasm of nearly all the muscles of the body to one of complete relaxation is certainly remarkable—this history is published with the hope that the experiment may be successfully repeated. Certainly great good and absolutely no harm may be expected. In the leg the sciatic, anterior crural and obturator are easily accessible, and in the rare cases of head tetanus the trunk of the facial could be reached, although the cephalic variety of the infection is so close to the vital centers and so fatal that any interference would probably be useless. Nevertheless, it should be tried. But inoculation of the spinal cord is probably equally essential, and after this experience in a bad case I should even be inclined to perform a laminectomy, open the dura, and after scratching the cord with the point of the needle, inject from one to two drachms of the antitoxin subdurally. It could not be injected into the substance of the cord, and experimentally it seems only necessary to inflict the most minute wound of nervous tissue to gain the desired effect with either toxin or antitoxin. An alternative is exposure of the nerves of the cauda equina and injection directly into their substance. This should not be more harmful than injection of the nerve trunks of the arm, which produced, in the instance detailed above, absolutely no ill results.

The effect of tetanus poisoning in the lower animals are not absolutely identical with those in man, as in animals the first manifestations are local, and in the region of the inoculation, while in man this is seldom the case; hence too sweeping conclusions from experimentation and from only one human cure are manifestly improper. But the results in this one case were so logical from what has been proved in animals and so satisfactory that I think there are grounds for some hope in what has hitherto been a hopeless condition.

102 East Thirtieth Street.

MULTIPLE GONORRHŒAL PERIARTHRITIS IN A CHILD, PROBABLY DUE TO INOCULATION THROUGH A WOUND.*

By HENRY HEIMAN, M.D.

NEW YORK.

ADJUNCT ATTENDING PHYSICIAN TO THE CHILDREN'S WARD, MOUNT SINAI HOSPITAL.

In a recent article on "Gonorrhœa in Infants," Kimball calls attention to the prevalence of gonorrhœa in infants and children, emphasizes the frequency with which the disease occurs in epidemic form in institutions, describes eight interesting cases of gonorrhœal pyæmia, and makes the suggestion that the mouth or upper-air passages may be the portal of entry.

Two years ago I observed a similar case, but did not report it because no authentic case of this nature was on record. As far as I know, Kimball is the first to report such cases, and it is his article that prompted me to write this paper.

In an article on "A Clinical and Bacteriological Study of the Gonococcus-Neisser as found in the Male Urethra and in the Vulvovaginal Tract of Children," which appeared in the Medical Record of June 22, 1895, I reviewed the literature of this subject up to that time, reported some cases in infants in which one or both of the parents were simultaneously suffering with the disease, and mentioned cases of vulvovaginitis and arthritis in which the mode of entrance of the gonococcus to the body was unknown. An endemic variety of gonorrhœal inflammation originating in hospitals was mentioned, and rigid isolation of such cases was advised. The adoption of proper measures to prevent the spread of gonorrhœa in institutions is a subject important enough to warrant repetition; for there are still in this city numerous institutions in which local epidemics of vulvovaginitis arise from time to time. "The law which makes it complusory to isolate such infectious diseases as diphtheria, scarlet fever, etc., would be just as applicable to cases of vulvovaginitis. The consensus of opinion seems to be that stuprum or direct contact, bedding, bath-tubs, thermometers, clothing, toys, chambers, closets, instruments, etc., are carriers of the poison of the disease."

While Kimball suggests that cases of systemic gonorrhœal infection such as he describes may arise from a stomatitis due to the gonococcus, he freely admits that his own view is not well substantiated. In only one of his cases were intracellular diploccocci decolorizing by Gram found in the mouth scrapings, and in this case the organism was not proved to be the gonococcus by pure culture. Moreover, in the numerous cases of so-called gonorrhœal stomatitis in infants that have been reported, not one was followed by gonorrhœal inflammation in other parts of the body.

Another possible mode of infection is by direct inoculation through a wound. I am not aware, however, that any such authentic case has been recorded. The case to be described is probably one of inoculation gonorrhœa.

The patient, a boy, is now four years old. I attended the child at birth, and have had the opportunity to observe him ever since. Delivery was normal. The patient had none of the diseases of childhood. He was perfectly well up to the age of two and a half years, when I was called to see him for an illness which was seemingly acute rheumatic fever. I learned that three days previously the boy had injured the sole of his right foot. Five days previous to this time the father had come to me with gonorrhœal urethretis, prostatitis, and epididymitis. Still earlier I had treated the mother for vulvovaginitis. Spreads and cultures revealed gonococci in the urethral discharge of both the father and mother.

The illness began with fever and pain in the feet. The child was unable to stand. Examination showed a temperature of 101° and the usual symptoms of fever. Throat, lungs, heart, and abdominal viscera were negative. The urine contained no albumin, sugar, or pus. No plasmodia in the blood. Both great toes and the left wrist were red, swollen, and excruciatingly painful. On the inner side of the sole of the right foot was a punctured wound about 1 cm. in diameter, discharging seropus; the wound had been treated by the family without medical aid. As regards diagnosis, scurvy was at once excluded, as the child was well nourished and on a general diet. Owing to the presence of the wound acute osteomyelitis was considered but was ruled out by the absence of local signs. Despite the infrequency of acute rheumatic fever in infants, this diagnosis was made tentatively. The fever and arthritic symptoms of the great toes failed, however, to respond to antirheumatic treatment. The plantar wound healed rapidly; the inflammation in the left wrist soon subsided;

*Read at the meeting of the Harlem Medical Association.

on the other hand, the periarthritis of the great toes showed no tendency to improve under general and local treatment. Three weeks after the onset, signs of suppuration about both first metatarsophalangeal joints had appeared. The presence of periarthritic suppuration suggested the diagnosis of gonorrhœal rheumatism, and the suppurating parts were then treated surgically by incision and drainage under chloroform narcosis. At the same time cover-glass specimens were prepared, and cultures were taken; the spreads were positive, and the chest-serum agar plates employed showed the presence of the gonococcus in pure culture. Shortly after this positive finding, cover-slip preparations and cultures from the conjunctiva, urethra, and rectum were taken with negative results. One month after the incisions, the wounds were healed. The temperature ranged from 101° to 104° F. throughout the illness; at no time were cardiac signs present, and physical examination has been negative ever since.

It is unfortunate that the nature of this case was not understood at the very outset, and that so little attention was paid to the original wound. Had cultures been taken from its discharge we might have been able to prove conclusively that this was a case of inoculation gonorrhœa. As it is, we can only state that the case in question is one in all probability.

It may be of interest to add that a left salpingo-oophorectomy was recently performed on the mother, and that examination of the pus from the tube by spreads and culture media showed the presence of the gonococcus.

56 West One Hundred and Twentieth Street.

Cystitis.—J. Henry Dowd in discussing this disease mentions three important symptoms, which, generally speaking, are always present: Frequency of urination, pain, and pus in the urine. Other symptoms at times are hæmaturia, ammoniacal fermentation due to decomposition of urea by bacteria forming the carbonate of ammonia, albumin in the urine, and general systemic disturbances. General symptoms depend entirely upon the condition present and the cause thereof. In acute cases the usual symptoms of inflammation are present, such as chilly sensations, fever, and the like. The writer says that, generally speaking, but two varieties of cystitis exist: (*a*) superficial, or where the mucous membrane and submucous tissue are involved; (*b*) interstitial, where the inflammation involves the muscular coats and interstitial tissue. As in inflammation of other parts, three factors are necessary: a weakened or damaged condition of the tissue; pyogenic bacteria; a medium for their development. The treatment of cystitis should be carried on from the following standpoint: (1) the cause; (2) relief of distressing symptoms; (3) rendering the urine bland and unirritating; (4) control of inflammatory process; (5) general treatment. The writer condemns searching an inflamed bladder for tumor, stone, or foreign bodies. The condition of the urine and the history of the case generally afford the necessary data. The writer then suggests the proper treatment in certain hypothetical cases which he describes. In acute cystitis he advises thorough evacuation of the bladder; a lukewarm solution of silver nitrate (distilled water must be used), 1-16,000, is placed in the bladder without a catheter by use of the Ultzmann-Dowd syringe. In a chronic case in which there is frequent urination, slight pain, with bleeding, and urine very acid with an excess of uric acid, the writer prescribes the following: Ext. hyoscyami, gr. j; ext. belladonna, gr. ½; tr. cantharidis, q.s. M. ft. pil. No. 1. This is given every three or four hours. All articles rich in uric or oxalic acid producing elements should be interdicted.—*Buffalo Medical Journal.*

Mitosis in Circulating Blood.—George Dock declares' after a thorough review of the literature, that on the whole the number of reports on mitosis in circulating blood is small, especially in comparison with the extensive literature on blood. Loewit observed a mitotic figure in the blood of a patient with "severe secondary anæmia." Prus noted the presence of distinct mitotic figures in a case of "splenic leukæmia." Spronck claimed that he found mitosis in the circulating leucocytes of healthy adults. Von Noorden saw a mitotic red cell in a case of pernicious anæmia. Other workers found this condition in cases of anæmia. Monti and Berggruen noted karyokinetic figures in the blood of infants. The writer had found mitotic figures in cases of acute anæmia; in cases of chronic pernicious anæmia; in a case of severe anæmia with splenomegaly of doubtful origin, in an infant, not rachitic, but possibly syphilitic; in eight cases of myelogenous leukæmia, and in one case of acute leukæmia. As to the kinds of cells containing mitoses, these were the red cells in seven cases of leukæmia and in the severe anæmias. In a case of acute leukæmia, one cell, and apparently a megaloblast, contained a good diaster. The writer thinks that at present we are not justified in claiming that mitosis in circulating blood has a definite diagnostic or prognostic value. In general it coincides with the occurrence of many nucleated red cells or myelocytes in the circulation. A typical mitosis is apparently a more serious condition than the normal process.—*The Physician and Surgeon.*

The Treatment of Hernia and Its Complications.—As a result of observations made in ninety-one cases of hernia, Dr. Orville Horwitz (Proceedings of the Philadelphia County Medical Society, January 30, 1904) has reached the following conclusions: The safety of the patient, as well as the lowering of the mortality, in cases of strangulated hernia depends on gentle taxis being practised for a short period, and, if unsuccessful, followed by immediate operation. Herniotomy for the relief of strangulated hernia in the aged is not a dangerous operation, provided it is performed as soon as possible after the constriction has taken place. An inflamed hernia should not be treated by taxis, but should be subjected to operation. No one method of attempted radical cure is applicable to every variety of rupture. The Bassini is suitable in the large majority of cases, the Bloodgood in those in which a large abdominal ring and weak or atrophied conjoined tendon are present. The means of relief for special forms and conditions of hernia must be suggested by the ingenuity of the surgeon, who will select the operation in accordance with the indications present. The palliative operation is applicable to a large number of selected cases of reducible hernia when the protrusion cannot be kept within the abdominal cavity by means of a truss, and also to some forms of incarcerated hernia. A radical cure may be safely attempted on patients between six and sixty years of age. Individuals that submit to what is known as the palliative operation should continue to wear a truss after recovery. In cases that cannot be submitted to a routine method of operation, the surgeon should strive to do that which would in his judgment be the best means of effecting the removal of the entire neck of the sac on a level with the parietal peritoneum. He should, if possible, firmly close the opening in the pertioneum after the removal of the sac; he should obliterate the depression of the peritoneum in the vicinity of the internal abdominal ring, bring the structures in apposition and close the apertures that form the canal through which the rupture protrudes. An aseptic result following a radical operation, with primary union, is essential to obtain a permanent cure of hernia. In cases of undescended testicle associated with hernia every effort should be made to save and transplant the organ. The method of operating for umbilical hernia suggested by Mayo is probably the most satisfactory hitherto suggested for that variety. Absorbable are preferable to non-absorbable sutures.

A CONSIDERATION OF DIABETES.

THE *Albany Medical Annals*, April, consists mainly of a series of articles dealing with diabetes considered from various standpoints. The first of these is by Dr. Richard M. Pearce, and discusses the pathology of the disease. The pathology of that form of the malady dependent upon lesion of the pancreas is solely considered, especial attention being paid to the influence exerted by the islands of Langerhans. It is pointed out that from the discovery of these structures by Langerhans in 1869, until within a few years, many and varied efforts have been made to explain their origin and function. They have been regarded from time to time as nervous elements primary ducts, embryonic remains, and as immature or wasted acini. The study of the ductless glands is largely responsible for the recognition of the similarity of structure of the islands and these organs. The structure of the islands—columns of cells rich in protoplasm, lying in an abundant vascular network of the sinusoidal character and with no excretory duct—naturally suggests as to their function the elaboration of some substance destined to be introduced into the circulation. This theory of the independence of the islands was first advanced by Shäfer, and received considerable support from the experiments of Ssobolew.

Again in the embryonic development of the islands Dr. Pearce insists that we have evidence that they are destined for some special function. As he demonstrated a short time ago, the islands at an early stage of the growth of the pancreas arise from the primary acini and for some time remain connected to these structures by a solid process of cells; but eventually become entirely separated, and with the development of a blood supply proportionately greater than that of the acinus, become anatomically independent. The writer therefore thinks that such anatomical differentation argues for a special function, and taking into consideration the recently accumulated knowledge, the result of pathological investigation, we are forced to the conclusion that this function is an internal secretion concerned in carbohydrate metabolism and conseqently of fundamental importance in any consideration of diabetes.

Dr. David L. Edsall of Philadelphia treats of the physiological chemistry of diabetes, and after giving a history of the disease, viewed from this standpoint, says the important facts known as to the nature of diabetes are unfortunately very few. When sifted down, they are found to be chiefly that the pancreas possesses an extremely important influence over carbohydrate metabolism; and that it is not knnow in what way this organ exerts its influence, except that it probably does not do so merely through providing a glycolytic ferment, but possibly through influencing the glycolytic activities of other tissues. Finally, it is becoming increasingly evident that carbohydrate metabolism is intimately associated, not only with the pancreas, but also with other tissues, and it is constantly assuming greater complexity than it has generally been conceived of exhibiting. At present, thinks the writer, one is justified in suspecting, at least, that carbohydrate metabolism is of a complexity that is comparable with that of proteid metabolism.

With regard to the medical treatment of diabetes, Dr. W. H. Thomson of New York, who writes on the subject, lays special emphasis on the point that functional medicines are only of use to relieve symptoms or to meet emergencies. In order to be of value in treating such a constitutional disease as diabetes, medicines other than functional must be sought. Dr. Thomson states that for a number of years he has had good results in the free administration of cod-liver oil in the treatment of diabetic patients. He also advocates the use of iron and certain medicinal antiseptics. To postpone diabetic coma as long as possible the writer recommends at the first symptoms of the approach of this condition, intestinal irrigation with hot normal saline solution.

Dr. Frederick C. Shattuck of Boston concludes the symposium with an article upon the general management of diabetes. He is of the opinion that the more diabetic patients are individualized, applying general principles to special cases, the better results shall we have. The writer does not believe in a rigid routine diet table, but is of the opinion that the diet should be adopted to each case. As to the length of time a strict diet is to be maintained, Dr. Shattuck says that this must depend upon the type of the disease, which, again largely depends upon the age and nutrition of the patient. He thinks it to be wiser, in milder cases, to keep the patient on a strict diet for one or two months, and then to test the tolerance for starch, giving first two or three ounces of bread daily and increasing the amount weekly as toleration warrants. In more severe cases, which are rendered sugar-free with difficulty, one must be more careful in allowing bread, and watch its effect even more closely. In the severest cases, in which the diet does not cause the sugar to disappear, it is ordinarily better to allow a fixed amount of bread. It is certainly so if under the strict diet weight and strength fall off, the sugar then being made from the nitrogenous food or the body tissues, the danger of acid intoxication being thereby increased.

Diabetic breads find but little favor with the writer, while if alcohol is considered desirable, the preference should be given to whiskey or brandy, a brut champagne, Moselle wine, or one of the California hocks. A day of starvation every two or three months has a beneficial effect in some cases. Special attention should be paid to the bowels, and particularly is this so if acetone and diacetic reactions are present in the urine. The skin should not be neglected, while great care should be taken to guard against cold. Worry and anxiety are to be avoided as far as possible, and muscular exercise should be taken in moderation, in that it burns sugar; in-

directly owing to the fact that it aids blood and lymph circulation. A change of climate during the winter may be of great importance.

In conclusion, Dr. Shattuck makes the following remark: "In the young, treatment of diabetes can at best only delay the fatal result. In those in the prime of life great service can generally be rendered, though actual cure occurs only in the minority of cases. In those past middle life the disease is usually well tolerated, and may be of comparatively little moment, provided that reasonable care be exercised; and yet, now and then we encounter cases the course of which proves other than first impressions would lead us to expect."

CHRONIC HABITUAL CONSTIPATION.

For the daily evacuation of the bowels a combination of several factors is necessary. In the first place the function of the muscular coat of the intestine and of the nerves controlling its activity must be neither excessive nor deficient. In the next place the secretions of the intestine and its accessory glands must be normal in quantity and in quality. Thirdly, the food-residue must be adequate in amount and capable of exerting a certain degree of irritation, in part from the presence and activity of fermentative bacteria. Finally the bowel must be habituated to regularity of action. Constipation may thus be due to a variety of causes, and these may be operative, singly or collectively. In many cases no doubt a condition of atony of the muscular coat of the intestine is present, while occasionally a state of spasticity may be the underlying factor. That in some instances, perhaps in many, the disorder is due to a too perfect digestion and absorption of the food, resulting in a deficiency of fecal matter, with diminished peristalsis, owing to absence of the products of fermentative activity, is not generally appreciated.

Observations have been made that go to show that not alone the total amount of fresh fæces is small in the case of individuals suffering from habitual constipation, but that the amount of dry substance is likewise greatly diminished as compared with the normal. Under such circumstances, further, the residue of food, including muscle-fibers, starch-cells, and cellulose membranes, has been found microscopically to be diminished, and likewise the number of bacteria. The conclusion has therefore been reached that chronic constipation is in some instances due to unduly perfect assimilation of the food in the stomach and small intestine, so that, among other things, there is an insufficiency of pabulum for the activity of the bacteria in the large intestine, with the result that the products of fermentation are generated in lesser amount and the stimulus to peristaltic activity is thus diminished in greater or lesser degree.

With the object of throwing additional light on this subject Dr. Hans Lohrisch (*Deutsches Archiv für klinische Medizin*, Nos. 3 and 4, Vol. 79) undertook a series of metabolism-experiments and found that the total amount of fecal matter discharged in cases of constipation was considerably diminished as compared with the normal—125.5:249.5. This diminution was due not alone to a lessened amount of water, but also to a lessened amount of dry substance, which was reduced almost one-half—33.9:59.3. The amounts of nitrogen, fat, and carbohydrates were also reduced, as well as that of cellulose. Further the difference in the number of calories eliminated by normal and constipated individuals was striking—namely, 266.1:190.2. When, on the other hand, constipation was induced artificially by the administration of opium and inhibition of peristalsis, the total amount of fecal matter was diminished, but this result was due to the large loss of water, the amount of dry substance being rather greater than normal. The evidence thus goes to support the view that in some cases of habitual constipation at least there is unduly perfect assimilation of the ingested food. That the deficiency in nitrogen, fat, carbohydrates, and cellulose is not due to the activity of bacteria is shown by the fact that these are actually diminished in number in cases of habitual constipation. It has, however, been suggested that the smaller number of bacteria present are afforded better opportunity for the exercise of their activities, but while such a view seems hardly probable it is difficult of contradiction, and the results of investigations on this point are inconclusive.

The practical lesson to be learned from the foregoing observations is that in cases of habitual constipation care should be taken to provide for a certain mass of physical bulk in the food advised, and in this connection fruits and vegetables subserve an especially useful purpose, and also for the ingestion of a definite and liberal supply of water.

Smallpox and Isolation.

Many of the opponents of vaccination contend that the chief reasons smallpox has so greatly decreased, are the general adoption of more efficient sanitation and the strict isolation of those suffering from the disease. When Germany is pointed to as a conspicuous example of the benefits of vaccination, these unbelievers say, but this result is not so greatly due to vaccination as to isolation. The British Local Government Board recently resolved to investigate the matter, and to decide as to whether isolation has been the main factor in practically driving smallpox out of Germany, or whether to vaccination must be given the credit for this desirable state of affairs. Accordingly Dr. Bruce Low, one of the inspectors of the Board, was despatched to Germany some few months ago with instructions to make a thorough investigation of the smallpox question. Dr. Low has performed the duty placed upon him, and has just published a report in which all the aspects of the situation are dealt with.

The law of Germany with regard to vaccination, is, as is well known, extremely strict and stringently enforced. This law requires infants to be vaccinated before the end of the calendar year following the year of birth, and all school children to be vaccinated in their twelfth year. The notification of smallpox is obligatory throughout the Empire, and all persons suffering, or suspected to be suffering, from smallpox can be ordered to hospital for isolation if, in the opinion of the medical officer of the local authority, the patient cannot be properly isolated at home. On the occurrence of a case of smallpox in a house, the "contacts" are immediately vaccinated or revaccinated; and in some towns they are removed to a place of isolation until the time for the development of the disease has passed away. The provision for "isolation" is nowhere of such a kind as would satisfy English practice or requirements.

A comparison of smallpox mortality cannot but convince the most prejudiced opponent of vaccination of the overwhelming superiority of German methods. Dr. Low supplies the following figures for the twelve years from 1891 to 1902 inclusive. In a population of over fifty-six millions the total German mortality for the twelve years was 607; the highest mortality for any year was 108, and the lowest was 51. In England and Wales, with a population of about two-thirds that of Germany the total mortality of the twelve years was 6,761; the highest mortality for any year was 2,461, and the lowest was 25. Dr. Low's general conclusion is that the German plan differs markedly from that employed in England and Wales by reason of the character of the so-called isolation. Untoward results to other presons from bringing smallpox to the sites of the general hospitals, have been seldom observed, and this, in Germany, is with one consent attributed to the protection afforded by statutory vaccination and revaccination, without which it is unanimously admitted that the method would break down. With this assistance Germany is able to dispense with separate smallpox hospitals and with any separate administration for the purpose of providing against the disease, and is thus freed, not only from a great expense, but from the suffering and inconvenience entailed upon England and Wales by the costly and half-hearted methods of dealing with epidemics as they arise, instead of preventing them from arising.

The instance of Germany, with reference to the methods in vogue there for the prevention of smallpox, is a conclusive proof that vaccination and revaccination, carried out thoroughly and conscientiously, confers so great an immunity against smallpox that other means of dealing with the disease are rendered superfluous. It would be well if other nations were to take the lesson taught by Germany to heart and follow in her footsteps. There are times when the objector to vaccination, however conscientious, must be ignored and his principles must be sacrificed for the public good.

Icterus in Secondary Syphilis.

Dr. W. J. Calvert, in the *Journal of Medical Sciences* for May, relates a case of icterus in secondary syphilis which came under his notice. This condition is of rare occurrence and when met is frequently not recognized as icterus. The literature, too, on the subject is scanty. Paracelsus in 1510 refers to icterus in secondary syphilis. In 1740 Astuc pointed out that icterus followed obstruction and congestion of the liver, as was later mentioned by von Swieten in 1743 and Fabre in 1765. Rosen de Rosentein in 1764 admitted the co-existence of icterus and syphilis, but thought the icterus was due to the mercurial treatment. Portal in 1812 admits that icterus is associated with secondary and tertiary syphilis; Guebler in 1852 reported five cases; and Luton in 1856 first pointed out the difference between icterus in secondary syphilis and that in catarrhal conditions. Three cases were reported in 1864 by Lancereaux; Lacombe in 1874, and Moreland in 1879, reported new cases, while Schroeder in 1887 reported seven cases. Engel Reimers in 1887 recorded a case of acute yellow atrophy in secondary syphilis terminating fatally. More recently Lasch, 1894, reported three of his own cases and forty-six from literature. Neumann in 1895 records fourteen cases; Lowenstein, one. From the record in Allgemeinen Krankenhause in Hamburg, Weiner reports fifty-seven new cases of icterus in secondary syphilis out of a total of 15,799 cases or 0.37 per cent. Aschner in 1896 reports three cases; and Jaumenne in 1899 two cases, making a total of 127 cases found in medical literature by Dr. Calvert.

As to the cause of icterus in syphilis, Lancereaux, Engel-Reimers, Quincke, and others think that is due to enlarged glands pressing on the bile-ducts. Senator Hutchinson and Chapotot agree with Guebler, who thinks the secondary eruptions in the intestines cause an obstruction in the flow of bile. Maurice thinks the hyperæmia of the bile capillaries, due to inflammation of the liver, is sufficient cause. Schroeder believes general catarrhal conditions, similar to the infectious diseases, exist, while Quadillac holds that the changes in the blood due to syphilis produce icterus. Several French writers think that the general condition of the nervous system plays a rôle. Neumann considers changes in the vessels a sufficient cause; Eichorst and others favor the chemicotoxic theory, and Liebermeister advocates Menkowsky's idea of acatactic or diffusious icterus.

Two types of this condition occur benign and grave. The writer says that the diagnosis of this manifestation is comparatively easy. There is a history and evident signs of syphilis and the following points are the most distinctive: (1) Appears in secondary stages of syphilis. (2) Simultaneous appearance with secondary lesions. (3) Influenced by specific treatment. (4) May vary in degree as the secondary eruption varies in intensity during the course of the disease, and, like the eruptions, may recur. (5) Rapid appearance without digestive disturbances. Dr. Calvert finally remarks that even grave cases are rarely fatal, and that treatment consists in ordinary treatment for syphilis in this stage.

News of the Week.

Dr. William Kelly Simpson of this city has been appointed consulting otologist to the Presbyterian Hospital.

Examination for Director of the Pathological Laboratories at Bellevue.—The Civil Service Commission will hold a competitive examination on June 7, 1904, for Director of Pathological Laboratories, Department of Bellevue and Allied Hospitals. Applications will be received by the commission, 61 Elm street, until May 28. The salary is $5,000 a year and the successful candidate will be required to devote all his time to the work, abstaining from private practice or connection with a medical college. The examination is open to residents of the State o f New York.

Generous Bequest to a Hospital in Philadelphia.—By the will of the late John N. Doak the sum of $20,000 is devised to the Methodist Hospital for the maintenance of four free beds in memory of the donor, his wife, and parents. An additional $200 is bequeathed for the purchase of the necessary furniture.

To Diminish the Dust Nuisance.—Arrangements have been made by the Street Cleaning Bureau of the city of Philadelphia to sprinkle certain prominent streets every two hours in the day during the summer; and also to flush the streets after having been swept with brooms, the streets subsequently being gone over by sweeping machines, and the dirt collected then carted away.

Tuberculosis among Street-sweepers.—Much excited comment has been indulged in by writers, both lay and medical, on a recent report to the effect that from one-fifth to one-third of the men in the Street Cleaning Department have been found to be suffering from tuberculosis. Long editorials have been written, and most important deductions drawn

from the alleged fact that the cause of this prevalence of consumption was the inhaling of bacilli by the men while sweeping up the dust on the streets. It appears, however, that the report was grossly exaggerated, and the latest news from the office of the Commissioner of Street Cleaning is that there is no foundation for the rumor about the tuberculosis epidemic. Less than 2 per cent. of the men in the department are suffering from consumption, and it is further stated that most of them had affected lungs before they became street-sweepers.

Resignation of Miss Clara Barton.—A new phase has been reached in the investigation of the American Red Cross. Miss Clara Barton resigned the presidency of the society on May 14, and has been succeeded by Mrs. John A. Logan, vice-president of the society. The change was affected quietly at the home of Mrs. Logan in Washington, where the executive committee met and accepted the resignation. Miss Barton read a letter reviewing her work in connection with the Red Cross, and concluded by expressing the wish that the organization would now "find that peace and quiet in its long disturbed elements so welcome to it, to us, and to the country. It is not believed, however, that this move will result in a breaking-off of the investigation, for the remonstrants insist that nothing short of a complete reorganization of the society with the election of an entire new set of officers will satisfy them.

American Confederation of Reciprocating Examining and Licensing Medical Boards.—Third annual meeting of this association will be held in the Great Northern Hotel, Chicago, on Tuesday, May 24, 1904. The first session begins at 9 A.M., the second at 2.30 P.M. All members and ex-members of medical examining boards and educators in medicine are invited to attend the meetings. The officers for 1904 are: *President*, Dr. W. A. Spurgeon, Muncie, Ind. (Member and ex-President Indiana State Board of Medical Examination and Registration); *Vice-Presidents*, Dr. H. Baxter, Cleveland, Ohio (Member Ohio State Board of Medical Registration and Examination), and Dr. John A. McKlveen, Chariton, Iowa (President Iowa State Board of Medical Examiners); *Secretary and Treasurer*, Dr. B. D. Harrison, Sault Ste. Marie, Mich. (Secretary Michigan State Board of Registration in Medicine).

The New Superintendent of Bellevue Hospital.—Dr. Willard P. Spratling, superintendent of the Craig Colony for Epileptics at Sonyea, near Rochester, N. Y., has been chosen superintendent of Bellevue and Allied Hospitals, to succeed Dr. William Mabon, who was recently appointed president of the State Commission in Lunacy. Dr. Spratling is a graduate of the College of Physicians and Surgeons, Baltimore, in 1886, and has been superintendent of the Craig Colony for several years.

American Urological Association.—The annual meeting of this association will be held at Atlantic City, June 8 and 9, 1904, under the presidency of Dr. Ramón Guitéras, 75 West Fifty-fifth Street, New York. The preliminary program contains twenty-nine titles. Authors who may desire to correct the titles of their papers are requested to notify the secretary, Dr. Ferd. C. Valentine, 31 West Sixty-first street, New York, before May 20. The annual dinner will be held at the Windsor Hotel on Wednesday, June 8, at 7.30 P.M. ($2 per plate). Members who desire to attend are requested to inform the President, stating the number of seats wanted. The following matters will be brought before the annual meeting: (1) Consideration of the invitation to affiliate with the American Medical Association. (2) Election of officers for the ensuing term.

Consolidation of the New York State Medical Associations.—At a meeting of the Joint Committee of Conference, held at the New York Academy of Medicine, May 6, 1904, the resolutions were passed that the president and the secretary of the Joint Committee of Conference be authorized and directed to make a certificate provided for in the tenth paragraph of the agreement, and the counsel of the committee be directed to proceed with diligence to obtain a final order for the consolidation of the corporations, pursuant to the terms of the agreement. Thirty out of thirty-five county associations have ratified. One, Onondaga, has refused to ratify, four have not yet reported. The associations that have ratified represent a membership of 1,711, and those that have not acted a membership of 42. The one refusing to ratify has 14 members. Ratifications have been received from 47 out of the 51 county societies, four have not yet acted. Those which have ratified represent a membership of 5,569. Those which have not yet acted a membership of 164. Article X of the agreement declares that "whenever the chairman and secretary of the joint conference committee shall certify that the conditions precedent to an application to the court have been fully complied with, the presidents of the respective corporations shall, and they are hereby authorized and required in the name and behalf of their respective corporations to petition the Supreme Court for an order to consolidate in accordance with the terms thereof." Therefore all county associations and societies that have not ratified will be asked to appear before the court at a specified date, appointed by the court, and show cause why the consolidation should not be completed according to the terms of the agreement, despite their failure to ratify.

Ambulances for London.—An effort is now being made in London to do away with the primitive method of handling street casualties, and to establish a system with most of the desirable features of the method in use in so many American cities, notably New York. To this end an association has been formed and an effort will be made to convince the London County Council of the utility of ambulances. A meeting was held on May 2, and resolutions were passed embodying this idea and suggesting making the Fire Brigade the basis on which to erect an ambulance system. Speeches in favor of the resolutions were made by Sir William Church, president of the Royal College of Physicians of London, by Mr. John Tweedy, President of the Royal College of Surgeons of England, and by Sir Thomas Barlow, and the New York system was described by Dr. E. Marion Cox, formerly of this city.

Night Classes of the Tuberculosis Clinic.—Dr. Thomas Darlington, President of the Board of Health, has decided to open a night class at the Tuberculosis Clinic of the Department of Health, the hours being from 8 to 9 P.M. on Monday, Wednesday, and Friday. This evening class began on Monday of this week. Since the opening of the clinic on March 1, 1904, from 250 to 300 patients a week have been in attendance from 9 A.M. to 4 P.M. This new clinic is for those patients who are unable to attend during the day. Special cards for the reference of patients to the clinic for diagnosis or treatment will be furnished on request. Physicians and others interested are cordially invited to visit the dispensary.

Physician Drugged and Left on Train.—Dr. J. A Boice of St. Agnes's Hospital, Baltimore, was taken

to St. Michael's Hospital, Newark, N. J., on the afternoon of May 11, suffering from what the physicians there said was poisoning. He was found unconscious on a Pennsylvania Railroad train due at Newark from Jersey City at 4 P.M. After being taken to the hospital he revived only long enough to reveal his identity. The police believe he was the victim of a carefully planned robbery, as he had neither jewelry nor money when taken to the hospital.

Smallpox in Theater.—According to Dr. Walter Bensel, Sanitary Superintendent of Brooklyn, a case of smallpox was detected on May 10, among the chorus of "Wang" at the Lyric Theatre. The man who was taken ill is now in the Kingston Avenue Hospital in Brooklyn. All the "Wang" company have been vaccinated, and the Lyric Theater has been thoroughly fumigated.

The New Bellevue Hospital.—The plans of the new Bellevue Hospital have been unanimously approved by the Municipal Art Commission to whom they were submitted recently.

Official Health Board News.—A notice, signed by Dr. Darlington, was recently posted in the Health Department building, to the effect that "in future no information relative to the work of the Department of Health shall be given to the public or representatives of newspapers without the personal sanction of the Board of Health," that is to say, of Dr. Darlington himself.

Radiotherapeutic Nurses.—Courses of instruction in the nursing of patients undergoing treatment with *x*-rays, the Finson light, etc., have recently been instituted in Berlin. Nurses who have taken these courses will receive a certificate of special proficiency in the care of *x*-ray patients.

Illness in the Japanese Army.—The correspondent of the *Sun* at Seoul reports that smallpox and typhoid fever are increasingly affecting the first Japanese army. Four thousand men are said to have been invalided home, while others are at the hospital stations in Corea. The authorities refuse to give any information concerning the sick.

Opposed to Kissing.—The Board of Health of Neenah, Wis., has issued an edict against kissing, and has asked that the custom be discontinued for the general good of the public. It is urged that the practice is dangerous in more ways than one and that it is a direct cause of the spread of contagious diseases.

Antisepsis in Paris Laundries.—The health authorities of Paris have presented to the Minister of Commerce, with recommendation that they be adopted, a number of rules for the guidance of laundresses. These call, among other provisions, for the use of closed bags for the conveyance of dirty linen, the thorough disinfection of all articles before they are washed, and the use by the washerwomen, for their own protection, of rubber gloves.

Revue Pratique des Maladies des Organes Génito-urinaires.—This new venture, which is to appear every second month under the editorial management of Dr. M. Gallois, is published at Lille and has the general appearance of a companion publication to a similarly named dermatological journal of Paris. It will be devoted to original contributions and a general review of the progress in genitourinary surgery and medicine for each preceding two months.

Old Manual Training School Rented.—The Board of Trustees of the Dearborn Medical College has leased the old Chicago Manual Training School building, together with the Pharmaceutical Department of the University of Illinois. Because of the removal of the school to its new quarters, the series of lectures to the police on first aid to the injured will be abandoned temporarily.

Donation to the Maurice Porter Hospital.—The Maurice Porter Hospital will be known in the future as the Children's Memorial Hospital. Mrs. Porter has given $75,000 toward a new building in memory of her son. This institution will be the nucleus of a new hospital where adequate provision for the care of the poor children of Chicago will be made.

Money for Augustana Hospital.—The Board of Directors of Augustana Hospital, Chicago, was authorized to borrow $100,000 with which to erect an addition to the hospital, at a recent conference of the Illinois Augustana Lutheran Synod. Dr. M. Wahlstrom was elected Superintendent of the Hospital, and Dr. G. C. Folsom of Galesburg, and Dr. Theodore Freeman of Chicago, were elected members of the Hospital Board.

Jewish Hospital Donation.—Mr. Julius Freiberg has sent his check for $25,000 to the Jewish Hospital, Cincinnati. The money is to be used for building an annex to the hospital for surgical operations. The gift was made on the anniversary of the death of Mrs. Freiberg. It was Mr. Freiberg's second gift to the institution, which now bids fair to be one of the best equipped in the United States.

Ohio Homœopathic Medical Society.—At a meeting of the society in Columbus, May 11, the following officers were elected: *President*, Dr. J. D. Nelson, Bellefontaine; *Vice-Presidents*, Drs. Sara E. Fletcher, Columbus, and J. A. Mitchell, Newark; *Secretary*, Dr. C. E. Silbernagei, Columbus; *Treasurer*, Dr. T. T. Church, Salem.

Protection from Tetanus.—The Springfield, Ohio, Council has passed an ordinance forbidding the use on July 4 of fire-crackers more than 7½ inches in length, of dynamite in any form, and of the toy pistol. Three Springfield boys died of tetanus from the toy pistol last Fourth of July.

Chicago Branch Hospitals.—Hospitals in several different sections of the city of Chicago, built by the county and maintained as branches of the County Hospital, have been proposed by the President of the County Board. The plan was outlined at a recent meeting, and was favorably received by the members. The plan is to submit to the people of the county at the election next fall the question of a bond issue for the creation of three branch hospitals, and the construction of new fireproof buildings in all instances where the county does not possess fireproof buildings more than two stories in height.

Medical Officers of the Illinois Militia.—An examination of candidates for medical officers for the Illinois National Guard was held at Rush Medical College on April 30. Eight candidates took the examination; of these, five were for the naval reserves, two were dental surgeons, and one examination was promotional. The range of subjects included anatomy, physiology, chemistry, materia medica and therapeutics, pathology and bacteriology, hygiene, and sanitation, military surgery, and practice of medicine. The naval candidates were examined on naval hygiene and sanitation, and the dentists on anatomy, physiology, and dentistry.

Iowa Provides for Reciprocity.—The Legislature of Iowa has empowered the Iowa State Board of Medical Examiners to allow physicians to register without examination when they come from States whose requirements for certificates are equal to those of Iowa. The system will not be in operation until certain practical details are arranged.

Charitable Bequests.—Mrs. Gordon Shillito of Cincinnati, who recently died, left $2,000 for the Children's Home; $2,000 for the Home for Friendless and Foundlings; and $1,000 to the Episcopal Hospital for Children.

Dr. Charles W. White was elected Health Officer to succeed himself by the Covington (Ky.) Board of Health last week. The term is two years, beginning May 12.

Monatsschrift für Harnkrankheiten und Sexuelle Hygiene.—This new journal, devoted to urinary diseases and sexual matters of hygiene, gives evidence, in the first issue, of having the support of worthy contributors and editorial direction which will win success. It is edited by Dr. Karl Ries of Stuttgart.

Ohio State Medical Association.—The association will hold it fifty-ninth annual meeting at Cleveland, Ohio, on May 18, 19, and 20. Dr. Brooks F. Beebe of Cincinnati, the chairman of the Publication Committee, has endeavored to secure as wide a representation as possible. The meetings will be in two sections, a medical and a surgical.

Presbyterian Hospital Internes.—Miss Karan Frederick and Mr. W. S. Keller have been appointed to the house staff in the Presbyterian Hospital, Cincinnati. Mr. Keller took his position on May 10, and Miss Frederick goes on in the autumn.

Isolation Hospital Abandoned.—After six years of setbacks and discouragements, the joint committee on an isolation hospital for the Oranges (N. J.) has thrown up the sponge. All the money subscribed toward the fund for site and construction, more than $10,000, will be returned to the givers. In every case property owners near prospective sites have objected successfully, and there seems to be no hope of obtaining a place where such a hospital can be built.

Race Suicide Discouraged.—In the Des Moines post office the following notice is posted: "Hereafter preference will be shown to clerks who are married, especially those with large families." The order is said to have come from the Post Office Department at Washington.

Obituary Notes.—Dr. ROBERTS BARTHOLOW died in Philadelphia on May 10, from pneumonia, at the age of seventy-two years. He was graduated in arts from Calvert College, and in medicine from the University of Maryland in 1852. He entered the United States Army as a surgeon in 1857 and continued in that capacity until 1864, when he resigned to become Professor of the Theory and Practice of Medicine in the Ohio Medical College. He later became dean in this institution, with which he remained connected until 1879, when he was elected Professor of Materia Medica and Therapeutics in Jefferson Medical College. He subsequently became dean for a short period in the latter institution, resigning in 1893 and becoming Emeritus Professor. Dr. Bartholow was an original investigator, particularly in the field of physiological therapeutics, and he made some important observations on cerebral localization. He made numerous contributions to medical literature, and he was the author of several recognized textbooks. He was a member of many learned societies, both foreign and domestic.

Dr. WILLIAM H. MCGEE, a leading physician of Warren County, N. J., died at his home in Belvidere on May 11, aged fifty-six years. He was a graduate of the Bellevue Hospital Medical College in the Class of 1872, and was a member of the Warren County Medical Society and resident surgeon of the Pennsylvania Railroad Company.

Dr. WILLIAM WATERWORTH, for twenty-two years a practising physician in Brooklyn, where he died at his home in that borough on May 11. He was born in Salem, Ohio, in 1851, was graduated from Adelbert College, and in 1878 from the Bellevue Hospital Medical College. He was a member of the American Medical Association, the New York State Medical Association, and the Medical Society of the County of Kings, and was surgeon to the Brooklyn Eye and Ear Hospital.

Dr. CRAYKE S. PRIESTLY died of pneumonia at his home in Des Moines on May 13. He was a graduate of the Medical Department of the University of Pennsylvania in the class of 1894, and came from a long line of medical practitioners. He was a descendant of Joseph Priestly, the discoverer of oxygen. He was a son of Dr. James Taggart Priestly of Des Moines, who survives him.

Dr. BERNARD MACKAY, a retired physician, residing in New York City, was killed on May 12, by being run over by a fire engine. He was born in England, seventy years ago, but came to this country at the age of thirty years, soon after receiving his medical degrees.

Dr. HENRY HUNTINGTON died at National City, Cal., April 27, in his eighty-sixth year. He was graduated from the Albany Medical College in 1866 and practised successively at Champlain, N. Y., Craftsburg, Vt., Atlanta, Ga., and Des Moines, Iowa. He went to California about ten years ago.

Dr. JARED W. DANIELS, a native of New Hampshire, died at Los Angeles, Cal., on May 3, at the age of seventy-seven years. Early in his professional career Dr. Daniels received appointment as resident physician to the Sioux Indians at the Yellow Medicine Agency and afterward was made an army surgeon. Most of his life was spent among the Sioux in Minnesota, until three years ago, he removed to Los Angeles.

Dr. JOHN MILTON DUFF died in Pittsburg, Pa., on May 14 of septicæmia, at the age of fifty-five years. He was graduated from Jefferson Medical College in the class of 1874. He participated as a soldier in the Civil War with Company B, 107th Pennsylvania Volunteers. He was clinical professor of gynecology in the West Penn Medical College, obstetrician-in-chief and abdominal surgeon to the Rhineman Hospital, surgeon to the South Side Hospital, and gynecologist to the Kaufman Clinic. He had been President of the Pittsburg and South Side Medical Societies and Chairman of the Section of Obstetrics and Gynecology of the American Medical Association. He was a frequent contributor to medical literature.

Dr. CHARLES WILLIAM NEWTON of Toledo, Ohio, died in Phœnix, Ariz., February 2, 1904, aged thirty-six years. He was a native of Marietta, O., a graduate of Marietta College in 1888, and of Ohio Medical College, Cincinnati, in 1891. He served as interne in the Good Samaritan Hospital, Cincinnati, and was for two years assistant surgeon at the National Military Home, Dayton, Ohio. In 1893 he established himself in practice in Toledo, where he became connected with the medical college and also with Toledo Hospital. In 1898 he was first assistant surgeon of Tenth Regiment O. V. I. A change of climate being necessary, he removed in 1903 to Arizona, where he became physician for the Western Navajo School on the Navajo Indian Reservation. Later he went to Phœnix, where he died. He was a member of the Toledo Medical Association, the Ohio Pediatric Society, the Loyal Legion, and the Spanish War Veterans. In 1894 he was married to Miss Elsie Eaton of Washington, D. C. She and two children survive him.

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent.)

SPITAL SATURDAY FUND AND HEALTH LECTURES—INFANTS' HEALTH SOCIETY—PUERPERAL ECLAMPSIA—LUMBAR PUNCTURE—CLIMATIC BUBO—LEEDS UNIVERSITY—DUBLIN COLLEGE—THE KING'S TRIP—FOOTBALL—EO ON CLIMATE, ETC.—A WOMAN'S BOOK—ANTI-VIVISECTIONISTS—OBITUARY NOTES.

LONDON, April 29, 1904.

IE Hospital Saturday Fund had a successful annual eting on the 23d, the Lord Mayor presiding. Sir S. ssley stated that the year's income exceeded by £710 at of 1902, the total being £23,674, the highest of any tained during the thirty years of the fund's operations. committee on sanatorium accommodation had been rmed. The Lady Mayoress then distributed a number first-aid and nursing certificates, after which Prof. R. Smith, President of the Royal Institute of Public alth, delivered an address on "Health, Public and rsonal." He said a great want of the present day is tention to questions of hygiene and the creation of health-conscience" in the minds of the people. At at point the work of public authorities seemed to stop ort, but the Royal Institute, of which he is president, s been giving lectures on such subjects, and he was eased to state that the Council of the Fund has taken eps to organize a crusade in that direction. He could omise cordial coöperation on the part of the royal body which he was president. They would be rewarded the consciousness that they were doing most effective ork in promoting health, lessening disease, and solving any of the problems which were perplexing the people. An "Infants' Health Society" has been started, to read a knowledge of the best methods of promoting e health of infants, to encourage such institutions as epôts for supplying pure milk and proper food, and to co-perate with other bodies having similar objects. It is oped when money comes in, to establish an institution tted with every arrangement for saving infant life and romoting scientific knowledge to that end.

Puerperal eclampsia has so tragic an interest that every ggestion as to treatment is sure to attract attention. n account of forty-one cases in which thyroid extract as freely employed was lately read at the Obstetrical ociety by Lieut.-Col. A. J. Sturmer, I. M. S. Ten grs. f the extract were given on admission and 5 grs. every our hours afterward. But other means were concurently employed, as morphine, saline injections in many ases. Rupture of the membranes, followed by dilatation of the cervix and early application of forceps, was sually practised. The mortality was reduced to 12.2 er cent. Colonel Sturmer said the urine considerably ncreased after two or three doses of extract and by the nd of twenty-four hours that increase was great; whereas, nder saline injections and morphine alone, improvement id not usually set in for twenty-four hours. Dr. Herman marked that increased urine was one of the most rustworthy indications of improvement, so that the xtract seemed to be of value. Dr. Nicholson thought he results of extract encouraging, but in severe cases e always gave morphine in addition. Dr. Malins remarked on the difficulty of determining the value of hyroid extract from cases in which other treatment ad also been used.

Eclampsia was also discussed at the Gynecological ociety on the 14th inst. *à propos* of a paper by Dr. T. . Helme, who said that to control the convulsions when hey had set in drugs were chiefly resorted to. He suggested, however, that withdrawal of cerebrospinal fluid y lumbar puncture would be more effectual and safer, s it would directly reduce the cerebrospinal tension, to he increase of which he attributed the convulsions. le reported a case in which this treatment had proved uccessful.

Dr. Macnaughton-Jones said no opinion could be xpressed on a single case, but if further experience conirmed Dr. Helme's view, puncture of the canal would be nost valuable. He thought pilocarpine was not sufficiently recognized as most valuable, and cited two cases n which the fits ceased as soon as profuse sweating roke out produced by a hypodermic injection of that rug.

Dr. B. Fenwick agreed that the fits were due to intraranial pressure as clearly explained by Dr. Helme, and, herefore, that treatment should be directed to the ascular system. Some years ago, acting on this idea, treated a succession of cases by bleeding from 15 up 25 ounces without drugs or injections of any kind, and recovered. Even without bleeding to such an extent, thought better results might be obtained by reducing the pelvic circulation by sulphate of soda and reducing heart pressure by means of amyl nitrite.

Dr. Hodgson testified to the value of pilocarpine and remarked that epileptic fits, which were not supposed to be due to cerebrospinal tension, were very like those of puerperal eclampsia.

Mr. Jordan asked what was the total amount of cerebrospinal fluid in the body. He hardly thought removing a drachm and a half would relieve intracranial pressure as much as venesection to, say, 15 ounces.

Dr. Helme, in reply, said he did not know if the amount of fluid had been determined, but as removing a few drops from a rubber ball full of water materially diminished its tension, he thought the abstraction of a drachm and a half of fluid from the cerebrospinal canal would have great influence. It would be dangerous to withdraw too much at once—six drachms had been followed by coma. He knew of a case of Bright's disease and lead poisoning in which drainage was allowed to go on after puncture until it stopped, which suggested that in some circumstances it might all escape without being fatal.

The affection called "climatic bubo" was the subject of a paper by Mr. James Cantlie and Prof. R. T. Hewlett, which is of special interest in relation to the spread of plague. Mr. Cantlie, who has had experience of both these diseases in China, thinks climatic bubo a form of pestis minor. He said it usually appeared before an epidemic of plague and continued afterward, especially attacking the white race. It ran a definite course of three or four weeks' fever, the glands affected enlarged and generally suppurated with but little pus, which has until now proved sterile. The gland should be excised, but as early excision does not arrest the disease it is better to delay doing so for two or three weeks. A case was described in a gentleman from Kolar gold fields with inguinal glands affected. He was seen by several who had experience of climatic bubo, and they agreed on that diagnosis. A gland was excised and Dr. Hewlett reported two forms of cocci were obtained—staphylococcus pyogenes albus and staphylococcus cereus albus. There was also a minute bacillus resembling closely that isolated by Kitasato in 1898 from a case of plague, but smaller, only about half the size, and rather more pointed. It stained by Gram's method and curdled milk. Did not stain very well with ordinary aniline dyes. On agar formed an extremely delicate growth resembling that of pneumococcus. Grew very slowly on gelatin, forming a white growth without liquefaction—more luxuriantly on serum, forming colonies resembling those of diphtheria, but whiter. This bacillus was not pathogenic for mice or guinea-pigs.

Dr. W. J. R. Simpson said he had often seen climatic bubo in Cape Town, and had met with a bacillus very like that described by the authors of the communication. This bacillus was obtained from a plague-infected cat, and the owner of the animal had a mild attack of plague, and the same bacillus was found in the glands removed. This form of bubo seemed always to precede the outbreak of plague.

Dr. A. E. Wright said there was only one plague bacillus, and he did not think this was a variety of it. He did not think there was any evidence that pestis minor could develop into plague. It was not proved that the enlargement of the glands was caused by either of the organisms described.

Dr. W. D'E. Emery said this bacillus somewhat resembled Sabouraud's acne bacillus. It might possibly be that it had reached the glands through a skin lesion.

Dr. E. Klein, who occupied the chair in this discussion, commented on the differences between Kitasato's bacillus and that of plague, and could not think they were the same—Kitasato had, indeed, modified his descriptions. As to the bacillus under discussion, it was difficult to identify it with another form. He had seen a similar one connected with the skin. Sections of the excised glands would help to decide whether the bacillus lay in the tissue, and he hoped if Mr. Cantlie had another opportunity he would investigate the distribution of the organism.

At the last meeting of the Pathological Society Dr. A. E. Wright read a paper on the value of a comparative examination of the blood and urine. He described a method of estimating the amount of salt in these fluids, which, jointly with Dr. Newport Kilner, he published in the *Lancet* of the 2d inst. He said that in judging of the efficiency of the kidney there were two points to consider, viz., the capacity of the kidney to eliminate (1) salt from the blood, (2) water. In a case of urticaria with a considerable amount of albumin in the urine, he found the salt normal, but the coagulation period of the blood prolonged to five minutes and the lime salts diminished. He concluded that the albumin was due to a serous hemorrhage into the kidney—not to structural

disease. Decrease of lime salts produces diminished coagulability and may be brought about by the introduction of soap, alcohol, sour fruit, gooseberries. The ingestion of such articles often produces urticaria. In all cases of renal disease Dr. Wright has found the excretory quotient of salt less than normal. In physiological albuminuria he found it normal.

Sometimes I have ventured to tell an enthusiastic footballer that his favorite sport seems rather a ruffianly game. If he plays Association he will admit that Rugby is somewhat dangerous, but if he is a Rugbean he will repudiate the general notion that Association is more fitted for younger teams. A pamphlet on "Football Injuries," by Dr. Whitelock, does not support the popular view, but shows that injuries are more frequent under Rugby rules but usually less serious, being sprains, wrenches, contusions, and so on, leaving no permanent damage behind them. On the other hand, he finds the Association game gives a smaller proportion of casualties, but they are generally more serious, not a few being injuries to the viscera. Another point the author brings out is the high proportion of injuries in both games at the beginning of the season. The same circumstance has been observed at Oxford, more injuries being inflicted in athletic games during the first fortnight of a term than during the six weeks succeeding. It is suggested that players at the beginning are not in sufficient condition to stand a strain they more easily sustain after a little practice.

Dr. Burney Yeo has revised and to a great extent rewritten his book on "Climate and Health Resorts," long out of print. A self-imposed winter holiday has afforded him the leisure to do so and perhaps added some practical experience. He has given the remodeled book the rather queer title of "The Therapeutics of Mineral Springs and Climates."

That the Obstetrical Society's diploma does what its council denies, in enabling unqualified women to pose as practitioners, is obvious from an advertisement of a new book on woman's ailments, by a woman who is C.O.S., Lond., and author of other works on health and sickness and how to manage the sick.

Leeds University is now to be reckoned among our institutions. The charter was received in the Yorkshire College and was read by the Vice-Chancellor in the College Hall on Tuesday. The next step is to complete the Establishment Fund of £100,000.

The most interesting incident of the Royal trip to Ireland is the laying of the foundation stone of the Royal College of Science in Dublin by the King yesterday. The telegrams stated that the stone was "well and truly laid," and His Majesty in reply to the address spoke of his sympathy with efforts to improve the material and intellectual condition of the country.

The Public Health Bill is still delayed. The revaccination bill's second reading is postponed.

The antivivisectionists met last night and uttered their usual denunciations. A live lord declared the "awful practice" to be "unscientific." A member of the lower house said if it was desirable "many persons could be found ready to be vivisected at a price," and so on. Neither of these legislators can be considered representatives of parliamentary wisdom.

Mr. Montagu H. C. Palmer of Newbury, Berks, died suddenly on Saturday evening, aged thirty-two. He studied at Cambridge and the London Hospital and took the double qualification in 1894. He was a member of the Newbury corporation and honorary curator of the museum. He succeeded to the practice of his late father, who was at one time mayor of the town, and who had himself succeeded to his father, Dr. Silas Palmer, and was a well-known antiquarian.

Among other deaths in the month now closing I may mention those of Surgeon-General Ward, I. M. S. (retired), aged eighty-seven; Surgeon F. C. Stearn, R.N., of peritonitis at Portsmouth, where he was on duty in the dockyard since 1902. He qualified in 1892. Dr. J. F. Taplin, suddenly, at Small Heath, where he had practised over thirty years, aged sixty-six. Dr. F. J. Lander, aged thirty-nine, killed in a bicycle accident, when riding with his wife, close to his house in Stamford.

Cocaine and Adrenalin.—James W. Robertson recommends, in operations for the cure of inguinal hernia, injecting the skin and muscular tissues with one-half per cent. solution of cocaine, containing from one to two drachms of adrenalin to the ounce. The advantages claimed are: (1) less chloroform; (2) less pain; (3) less capillary hemorrhages and (4) a better view of the parts operated upon.—*Northwestern Lancet.*

LETTER FROM THE PHILIPPINES.

(From Our Special Correspondent.)

MANILA, March 8, 1904.

IN view of the relatively high mortality attending the inoculation against rinderpest of the carabao being purchased by the Government in China, this inoculation will hereafter be done in Manila by the employees of the Serum Laboratory. Heretofore the Government risk was assumed after the animals had been inoculated at Shanghai, and the loss there was so great that the contractors succeeded in securing permission to have immunization done here. This importation of carabao for the restocking of the islands, following the tremendous losses from epidemic animal diseases during the past four years, has not, however, been by any means an unqualified success. These imported carabao have been brought from the much colder climate of the northern half of China and from quite different environment. On arrival in the Philippines they are brought under conditions for which acclimatization is necessary, and are exposed to diseases which do not prevail in the districts from which they come. They are depressed by the hardships of a long sea voyage, the sickness incident to inoculation against rinderpest enfeebles their power of resistance, and the change from wintry cold at Shanghai to the tropical temperature of Manila, together with a change of diet, exacts an unfavorable effect upon them. While protected against rinderpest, a large number of them contract surra, and experience has shown that when this disease once appears in a herd every animal ultimately becomes infected, even if daily blood examinations are made and animals so found to be infected are promptly removed and destroyed. The explanation of this would seem to be that an animal may harbor a latent surra infection during the period of incubation without presenting any symptoms of sickness or having the parasite discoverable in the blood by microscopical examination, and that biting flies may convey such infected blood to other animals before the existence of any disease can be clinically or microscopically determined. So far, the most successful plan appears to be to break up each shipment of carabao into small bunches, well scattered, and to have these small herds frequently examined by veterinarians, destroy without delay any animals found diseased: but this plan is not always practicable and requires a vast amount of veterinary service. Surra is a disease which, in horses, destroys life in two or three weeks, but in carabao it assumes a chronic form which may persist for many months without apparently affecting the strength or condition of the carabao, even when the blood of the animal is almost constantly found to be swarming with parasites. The infected animal ultimately falls sick, however, and then succumbs within a very few days. It is probable that such carabao are the main sources of infection from which the disease is spread, by virtue of the long carriage of the infection. Horses are less potent in maintaining an infection as they soon cease to be foci of the disease from early death. Recently an examination of the blood of all the carabao in the city of Manila was made, and in more than a thousand so examined a proportion of 3.9 per cent. was found to show the infection of surra, the diseased animal being pretty well distributed over the city.

Custom officers have been ordered to refuse hereafter to allow the landing of diseased animals in Manila, except for purposes of cremation or for experimental study in the laboratories, except on written order from the Board of Health. Animals not so landed must be returned to the port of shipment or otherwise disposed of outside the jurisdiction of the Philippine Islands. Several wily Chinese thought they saw an opportunity to make money by bringing sick animals ashore on cremation permits and then slaughtering them for food, but their action was promptly detected and they are now before the courts to answer for their misdeeds.

Plans, estimates, and specifications for the proposed General Hospital in Manila have been prepared by the Insular architect and submitted to the commission. The site selected is in the vicinity of the new Government laboratories on Calle Herran, on a plot of ground of about twenty-three acres. The plan calls for the opening of a new street, and also provides space on which the buildings of a medical school may subsequently be erected. The plans are based upon a 300-bed hospital, with provision for further expansion to 1,200 to 1,400 beds by the erection of additional pavilion wards and the utilization of certain sound buildings, now existing in the immediate vicinity, as wards. The 300-bed hospital contemplates the erection of twenty-five buildings, of which eleven are medical and surgical wards. There is also a reception ward, and buildings for administration, operations, bath house, insane ward, kitchen and cold storage,

laundry, disinfecting plant, quarters for male attendants, female nurses' home, maternity pavilion, ambulance stable, morgue, crematory, and chapel. The male wards have a capacity of 148 beds, divided equally between the medical and surgical sections. The female medical wards have 88 beds, with a surgical side of 48 beds and a maternity ward of 16 beds. The nurses' home has accommodations for 34 female nurses. The administration building contains offices, consultation rooms, dispensary and facilities for an out-patient clinic. The operating pavilion contains four amphitheatres, also anæsthetizing, sterilizing and dressing rooms, and rooms for *x*-ray, photography, and medico-mechanical apparatus. The maternity pavilion, bath house, kitchen, laundry, morgue, crematory, and chapel are very complete. The drainage and sewerage systems present some difficulties, because of the flat nature of the site, but on the other hand heating facilities do not have to be considered and a considerable saving is effected thereby. The buildings coming into direct use in the care of the sick are to be of wooden frames, lined outside and inside with iron lath covered with plaster rubbed to a smooth finish, the ground surfaces are to be concreted, the floors of terrazo, and the roofs and stairs of iron. The other buildings are to be of hard native woods. The cost of the 300-bed hospital is estimated at more than $600,000, or $2,143 per bed, which is extremely high as compared with similar institutions elsewhere, even when the latter includes the installation of expensive heating arrangements. If the hospital is expanded to 1,400 beds, the total cost is estimated at $1,300,000, or $940 per bed. There is an opinion that the cost of the hospital as planned is unnecessarily high, and may be considerably reduced without impairment of efficiency, particular since the contagious disease hospital recently erected in Manila cost only about $300 for each of its 120 beds, and if expanded to its proposed size of $225 beds would only cost about $200 per bed. In this climate, where internal heat does not have to be conserved and heating arrangements are not required, there should be a far greater economy in building construction than is shown in the above estimates, and it is probable that the authorities will take this view and return the plans to the architect for further consideration or appoint a board to further consider this important matter.

The commission has lately passed an act requiring all provincial and municipal health officers to give medical attendance without charge to any officer or enlisted man of the constabulary, when called upon to do so by the officer in command of the constabulary of that district or province. The same service must be rendered free to any indigent person under the direction of the governor of the province or the president of the municipality. The law also states that no pay for medical services can be received by provincial or municipal health officers from persons entitled to them by law.

Dr. C. S. Gilchrist has been appointed surgeon to the large engineering force constructing the road from Vigan into the province of Abra. Dr. Gilchrist came to the Philippines with the Thirty-ninth Volunteers, and has lately been an assistant at the quarantine station at Mariveles, and in the port quarantine service in Manila Bay.

A rather gruesome occurrence took place some time since in connection with the garroting of four condemned murderers in the province of Isabela. It appears that the American judge sentencing these men declined to witness their execution, embarking on a boat lying in the Rio Grande, opposite the prison. The execution was witnessed by several Americans, and the act of death certified by a native doctor and several provincial officials. This death certificate was brought to the judge, who signed it and at once departed down the river. The bodies of the four garroted men were removed to the church and laid out preparatory to a funeral service to be held later, and about three hours after the supposed execution two of the garroted men showed signs of returning consciousness and ultimately returned to life, with no worse results than badly bruised and wrenched necks. This put the judge, doctor, and others who had certified to the fact of death in an embarrassing position, and raised a very serious question as to the legal status of the men themselves. The records in their cases had been officially closed by a certificate of execution and they could thus have no legal existence. Apparently they could not be held or proceeded against in the courts, not having a legal entity; but, on the other hand, if they were allowed to go free and committed any further depredation, they could be shot down by the injured party without fear of punishment for such action. As a matter of law, a judgment cannot be attached except where accident, mistake, or fraud has crept into the record, but this cannot be at the instance of the party responsible for the mistake, as the Government was in the present instance. The condemned men certainly committed an intentional fraud in surviving after the Government executioner had choked them into insensibility, and in passing through such an experience it would certainly seem as if they had paid a large portion of the debt due. The Government has, however, held the survivors in custody, and recently the Governor has imposed a sentence of life imprisonment in lieu of the uncompleted one of death by the garrote. It is understood that the existence of these men having thus been legally recognized, they will now demand that they be heard in the courts, where they propose to contest the latest action of the governor. The case is one of such peculiar nature that the medicolegal questions raised will be of unusual interest and much importance.

The above experience is in marked contrast with a recent execution by the garrote in Bilibid Prison, where the fact of death was certified to in four minutes after the screw was turned. Death was apparently instantaneous and without pain, and the method was very favorably commented on, as compared to hanging by the Americans, who witnessed the execution. The unfortunate episode in Isabela province was apparently not the fault of the method, but the half-hearted and ineffective way in which it was carried out. It is a Spanish tradition, that it takes eight minutes to cause death by the garrote, but that the bodies should be left in the machine for four hours, and it is said that in Spain or the Philippines no executioner ever made a failure of his job on the above basis.

Progress of Medical Science.

The Boston Medical and Surgical Journal, May 12, 1904.

The Danger of Infection to the Attendants of Tuberculous Patients.—Louis Faugeres Bishop declares that the idea that tuberculosis is of necessity contagious, is not strictly true. We all take in germs of tuberculosis from time to time. There will be fewer tubercle bacilli found in the tuberculous ward of a hospital than in the air of a dusty street, for in a crowded street all conditions are favorable. We do not get tuberculosis because we enjoy a natural immunity against it. The tubercle bacilli may be introduced into the human body, but there will, ordinarily, be no ill effect. The one exception is in the case of a very severe infection if the person is inoculated with the germs of tuberculosis repeatedly, and the natural immunity temporarily broken down; but even then if the individual is not susceptible he will throw it off. Many people are afflicted with this disease for a little while, but the condition is not recognized, and the lesions heal and the patient recovers. The writer hardly considers it fair to put tuberculosis in the same category with other contagious diseases because it is only contagious in the sense that it may be transmitted from one to another, but is not contagious in the sense that the average person is liable to catch it. As far as danger in taking care of tuberculous patients is concerned, it is practically nil.

Hysteroneuroses and Their Relation to the Physical Examination of All Women Patients.—Daniel H. Craig believes that physical examination occupies the same position relative to the hysteroneuroses that judge and jury occupy to the accused, or suspected, criminal. Engelmann's definition of hysteroneuroses is: "Those phenomena which simulate a morbid condition in an organ which is in an anatomically healthy state, and which are due, not to structural changes in the organ in which they appear, but to morbid or physiological changes in the uterus or ovaries." The writer says that to uterus and ovaries he would like to add kidneys. The more thorough the physical examination of all women patients, the less opportunity there will be for over- or underestimating the hysteroneuroses. For his students, the writer has formulated the following rule: "Never accept any symptom as an hysteroneurosis until every other possible cause has been rationally ruled out." A pelvic examination is not necessary in the case of every woman. The physician should make a thorough study of etiology, pathogenesis, and pathology. If a thorough search be made for extra pelvic causes of symptoms, all necessity for intrapelvic examination may often prove wanting. Pelvic lesions may cause distant neuroses with pelvic symptoms so slight as to have been overlooked by the patient. After a thorough examination of the seat of reflex symptoms without discovery of the cause, pelvic examination may give the happiest results. One condition in which the hysteroneuroses have been made a diagnostic scapegoat is the menopause. When hysteroneuroses or local pelvic symptoms arise at the beginning of the menopause, they should be treated just as at any period of a woman's existence. Many cases of cervical carcinoma would then be recognized early. Comprehensive physical examination will sometimes discover that the patient is suffering from two or more distinct pathogenies in no way related to each other except in so far as both disturb general metab-

olism. The writer then gives a general outline of examination in the case of a new patient. He calls attention to the intimate relationship existent between respiratory and intrapelvic lesions. In supersensitive patients, the use of nitrous oxide greatly facilitates pelvic explorations. The writer then reviews the histories of several patients which emphasize the paramount importance of thorough and careful physical examinations.

Journal of the American Medical Association, May 14, 1904.

The Prevention of Tetanus.—D. Eisendrath reviews the literature of the prevention of tetanus and describes the procedures which, during recent years, have proven successful in his hands. The essential feature is to convert a closed wound filled with necrotic débris, blood-clots, cartridge-wads, etc., into an open one. His postulates for the successful treatment of wounds so as to prevent tetanus are as follows: (1) Early and thorough exposure of every portion of the tract which has been infected by the blank cartridge or instrument which caused the punctured wound, retracting the edges, so that the disinfection and removal of the infected tissues can be done under the guidance of the eye. (2) Prophylactic injections of tetanus antitoxin to aid the organism in combating whatever toxins may have been absorbed prior to the time of operation. (3) This thorough disinfection can only be carried out under anæsthesia, either local or general, and when the parts are rendered bloodless by the application of a constrictor. (4) The blank cartridge itself does not contain tetanus bacilli, but undoubtedly carries them in while penetrating the skin. (5) The instruments which cause punctured wounds either are covered as described above with tetanus bacilli or the manure of horses, etc., and are thus carried into the wound. (6) Our only hope in reducing the high mortality of tetanus is in a thorough application of such radical measures as have just been described.

Acute Ascending Paralysis and Landry's Paralysis.—According to L. H. Mettler, these two names are used synonomously, yet the two conditions are by no means the same, although there is a middle ground where they overlap. The author's paper is a discussion of the following propositions: (1) Landry himself described not a new disease but rather a symptom-complex or clinical picture, which included much less than what is now included under the term acute ascending paralysis. (2) Both Landry's disease and acute ascending paralysis are recognized to-day as mere phases of a particular form of specific intoxication of the nervous system. (3) The proof that this intoxication is of bacterial origin, the particular microorganism, if, indeed, there is a particular one being still unknown, is about established. (4) This bacterial intoxication produces functional disturbances, and later on diffuse inflammatory and degenerative changes in various parts of the central and peripheral nervous apparatus, thus accounting for the variability of the clinical phenomena. (5) Time, virulence of the poison and resistive power of the patient are the principal factors that determine the nature of the pathological findings and the clinical form of the trouble. Under some circumstances the post-mortem findings may be *nil*, while under other circumstances they may be highly suggestive of a diffuse myelitis, an acute anterior poliomyelitis or a peripheral multiple neuritis. It is an error, therefore, to identify Landry's paralysis, or even acute ascending paralysis, always with one or the other of these diseases. (6) The recognition of the class of cases under discussion, as a form of diffuse bacterial intoxication, not only explains most satisfactorily their striking clinical discrepancies, but suggests a far more rational guide for their management than has any explanation hitherto offered.

Medical News, May 14, 1904.

The Ammonium Sulphate Method of Sterilizing Catgut—Weller Van Hook recommends this method. It depends upon the principle that organic substances are insoluble in the fluids by which they are precipitated from their solutions. A saturated solution of ammonium sulphate answers these requirements. The writer has found that slightly chromicizing the material before sterilization prevents it from weakening and softening, and yields a product more easily handled and tied. The raw, rough, unbleached material should be chosen, and should be soaked for a week in pure ether or a mixture of chloroform one part and ether two parts. It is to be wound on glass spools in single layers and soaked for three days in aqueous solution of chromic acid, 1 to 1000. It is boiled for twenty minutes in water to which, while boiling, chemically pure ammonium sulphate has been added until the crystals cease to dissolve. The catgut is washed for half an hour in cold sterile water, and stored as desired. Should the material become infected, it may be reboiled. The writer places the spools in a solution of corrosive sublimate, one part in 95 per cent. alcohol, 1,000 parts.

A Case of Carcinoma of Retained Testis.—Sinclair Tousey reports this case which came under his care. The patient was a man of thirty-three years, with both tuberculosis and cancer in his family history. He was born with a number of malformations. Both testes were completely within the abdominal cavity. There was an inguinal hernia and an exaggerated hypospadias with apparent absence of the penis. This condition was operated on unsuccessfully. About twelve years later the patient began to have fainting spells with pain in the lumbar region; later convulsions occurred after overwork or exposure. In about two years there was an attack of intense pain in the small of the back, supposed to be of a rheumatic, neuralgic, or tuberculous origin. This continued for about a year. The condition was then found to be one of enormous swelling of the colon, forming a genuine enteroptosis. The application of a Rose's belt reduced the swelling in forty-eight hours to such an extent that the tumor could be felt. The tumor occupied the entire lower part of the abdomen from two inches above the umbilicus. This felt softer and cystic on the right side. A diagnosis of retained testis was made. At operation the tumor appeared at first like a fibroid uterus, but later a part of it was found to be a cyst. A digital prolongation extended from the cyst down into the hernial sac. The entire mass was removed without rupturing the sac. The solid part of the tumor weighed about four pounds. Microscopical examination showed this to be carcinoma with a considerable amount of soft fibrous tissue. None of the normal testis tissue could be distinguished microscopically. The patient made a rapid recovery, but recurrence took place in two months. Pain in the back returned, and he died about five and one-half months after the operation. At the autopsy the body was found in a frightful state of decomposition. The direct cause of death seemed to be an occlusion of the abdominal aorta caused by the pressure of the growth.

Asthenopia: A Clinical Study.—D. H. Wiesner defines the term "asthenopia" as a compound derivative, meaning without strong sight; ordinarily called "eye-strain." The writer shows that poor vision is becoming more and more frequent, especially in crowded populous cities. The cause lies in the close application of the eyes for many hours each day and far into the night, and that at close range. The first variety of asthenopia mentioned is the accommodative. In order to see clearly at close range, the ciliary muscle must be called into action. Hyperopes of any large degree have to use this muscle of accommodation for distant vision; with this refractive error, symptoms of eye-strain are common. The act of accommodation is accompanied and assisted by the act of convergence, both internal recti taking part in it. If this convergence be long continued, an overstrained muscle will assert itself. Nervous, hysterical, or psychical asthenopia is also met with. In simple hyperopia eye-strain is common; in hyperopic astigmatism it is usual; and in compound hyperopic astigmatism it is the general rule. In myopia, with the exception of the reduced distant vision, eye-strain is not met with. With myotic astigmatism eye-strain is noted, and also with the compound variety. The large majority of cases are those with hyperopia, with or without astigmatism, because the accommodative act is so continuously required. Sex does not enter materially into the diagnosis, temperament does, and age is a factor. Headache is a prominent symptom, so are blurring of vision and lacrimation. Diplopia is not infrequent. In spasmodic twitchings of the lids, a slight rubbing of the lids will generally bring relief. Blepharospasm is at times encountered as a direct result of asthenopia, and is hard to overcome. Certain inflammatory conditions result, from eye-strain usually of the refractive kind—blepharitis marginalis, hordeolum, and chalazion. The writer calls attention to the importance of limiting the treatment of the eyes to those who are qualified for this work.

New York Medical Journal, May 14, 1904.

Prostatic Crises.—Under this term S. H. Friend refers to the perineal pain which is one of the early symptoms of tabes and is located, according to the author, in the prostate gland. He refers to three patients in whom the pain occurred after coitus or nocturnal emission. In one case the pain came on during the day while the patient was riding in the street cars. These prostatic pains last steadily for from three to five minutes and do not recur. The patients closely examined themselves at the author's request and found that after each "crisis" the tissues of the perineum were yielding and not tender, that the rectum was soft, the insertion of the finger causing no pain and that the point of tenderness lay in the anterior wall of the rectum opposite the prostate gland. The latter is therefore considered as the starting point of the pain.

Intussusception.—J. F. Erdman believes that this condition calls for abdominal section, and that it is generally a waste of time to temporize with inflation or water injections. As to diagnosis the presence of a tumor in the abdomen is a most fallacious sign. In over 60 per cent. of a series of twenty-six cases, in all but three of which operation was done by the author, no tumor of any kind could be made out. The great diagnostic sign is blood, bloody serum, or mucus, either in the stool or expelled after rectal examination with the finger. There is some fever and quickened pulse. The author describes his manner of operating, using chloroform so as to lessen the liability of vomiting, making the incision in the middle third of the right rectus muscle and avoiding traction on the bowel. He gives the histories of two interesting cases. In one, preparations had been made for operation but spontaneous reduction occurred six hours after an enema had been given, this having been administered before the case was seen by the surgeon. In a second case, one of the subacute variety, of six days' duration, operation was successfully done. In the case recovering spontaneously there had been some abdominal manipulation and massage, and to these rather than to the enema the author attributes the happy outcome.

Mucous Colitis with Special Reference to Therapy.—F. J. Runyon states that if there is much abdominal pain and soreness, if much mucus is discharged, and if the latter is blood tinged, the patient must be put to bed and kept there till these acute symptoms have subsided. Constipation calls for liquid diet. Milk should be avoided, as it forms scybalous masses. Beef juice and broth are to be preferred, and to these bread and some of the cereals may be added, the whole being strained. Fruit juices are allowed. If diarrhœa is present, we should give a dry diet, such as toasted biscuit, rice, and broiled meats in moderation, a little tea being allowed. After the diarrhœa is checked we may give any food easy of digestion that does not contain coarse substances. We should prohibit corn bread, oatmeal, tomatoes, pastry fried foods, and sweets. For general tonic measures, cold baths, massage, electricity, all are indicated. The bowel must be thoroughly flushed, and for this purpose nothing is better than Epsom salts. Warm normal salt injections are also of service, and to these various astringent agents may be added. For the obstinate cases a right colotomy is sometimes necessary. The author states that he has seen it suggested that the appendix be utilized for the purpose in these obstinate cases of washing out the colon, the point of the syringe being introduced into the appendix, previously exposed and opened for the purpose. The appendix is left exposed and utilized for this as long as it is deemed advisable.

American Medicine, May 14, 1904.

The Puerpera: Her Care and Comfort During Convalescence, Particularly the Prevention of Visceral Prolapse.—A. Ernest Gallant believes that, from the standpoint of an up-to-date obstetrician, it is the duty of all such specialists to devote more time and attention to the local and general condition of the puerperal woman, in order that she may get up from the puerperal bed in every respect a healthy individual. For this purpose it is necessary that following labor, she secure proper rest and food, that the bowels act freely, that by insisting on the lateral or abdominal posture, avoiding the dorsal position, the uterus be encouraged to contract in its normal relation to the bladder, and after the first week by the use of tampons overcome any tendency to uterine displacement, or prevent its recurrence, if present before pregnancy, and continue the good effect by inserting a pessary, to be worn until assured that the uterus will remain in its proper position. For the relief of soreness, stiffness, and after-weakness, loss of muscular tone and strength, the prevention of abdominal laxness and consequent visceral prolapse, the patient must receive general massage for the first three days, massage with passive and active motions for the fourth, fifth, and sixth days, and be taught suitable exercises for strengthening the muscles of the abdomen, back, and extremities during the succeeding days in bed, and practise daily after she is permitted to get out of bed. As long as the patient is in bed, she should wear a snugly fitting abdominal binder, held in position by perineal straps. When she is out of bed she should wear a specially fitted corset, put on while in the dorsal position. The writer has had excellent success with this method of treatment in his cases.

Is the Epileptic Attack Explosive in Character?—J. W. Wherry gives interesting data in regard to mental confusion deepening into unconsciousness in several epileptics just prior to the convulsion. He presents the copy of a letter written by an epileptic which shows undoubtedly the gradual loss of consciousness which he believes is present in all cases of epilepsy, even though there is no visible evidence except as secured by accident. This initial stage of gradually increasing loss of consciousness gives rise to peculiar and confused sensations to which the name aura has been given. This aura is probably present in practically every case of true epilepsy. The writer believes that if the unconsciousness is due solely to the explosive character of the convulsion, there could then be no loss of consciousness until after the convulsion had been initiated. The condition of unconsciousness and the convulsion bear no closer relation to each other than that they are both the result of an identical elemental cause, each representing a stage in the epileptic attack. Unconsciousness precedes the convulsion. The treatment of epilepsy must ever remain unsatisfactory so long as it is directed exclusively toward the convulsion, or exclusively toward any single symptom of the epileptic condition. The writer then discusses the subject of methæmoglobin. He gives the key to the situation as follows: Remembering that the onset of the epileptic attack is not dynamic or explosive, and that the prime cause of epilepsy is an element, toxic, infectious, or whatever it may be, possessing a double characteristic: (1) to produce unconsciousness; (2) to cause convulsions; and then remembering that treatment to be effective must be directed toward those causes only which possess within themselves these two qualities. Given a toxin that will convert the oxyhæmoglobin in the blood into methæmoglobin, and the problem is solved; for from that moment the process of reconstruction is identical with that of the epileptic attack. The writer believes that back of the epileptic attack is a toxic condition which, if present in some individuals, not epileptics, would give rise to a symptom-complex identical with that found in epilepsy, and that heredity is indicated in the functional perversion which leads to the production of the prime cause, rather than in the resultant unconsciousness and convulsion.

The Lancet, May 7, 1904.

Amaas, or Kaffir Milkpox.—W. E. De Korte defines this disease as a specific contagious eruptive fever closely resembling smallpox in appearance, yet differing from it in some respects. The disease affects the pure-blooded native rather than the mulatto, and the white man is almost entirely immune. Vaccination or a previous attack of smallpox in the negro affords nearly absolute protection against amaas, yet vaccination of natives convalescent from amaas very often "takes" in a modified form. The period of incubation is, like that of smallpox, from ten to fourteen days, and similarly the eruption also appears on the third day. Defervescence occurs, as in smallpox, with the appearance of the eruption, but there is no secondary fever. The mortality from amaas is very slight, and the disease is especially mild in infants and children, often aborting, indeed, in sucklings. The general symptoms are headache and occasional backache, slight coryza, mild sore throat, enlargement of the cervical glands, fever, and vomiting.

Carbolic Acid Poisoning in an Infant.—Louis E. Stevenson reports the case of an infant, six weeks old, whom he circumcised on March 10. The wound was dressed with lint soaked in carbolic oil (1 in 20). The little patient was very well all day, sleeping most of the time, and had a good night. Early next morning he vomited and had apparently nausea at intervals during the day but did not vomit any more. He had two normal motions. During the afternoon the napkins were stained a dark color. The carbolic dressing was discontinued. On March 12 he was rather restless with no sound sleep. The appetite was poor and the urine was scanty and dark colored. He had two motions, one of which was dark in color. He had a very restless night, scarcely sleeping at all. On the 13th the patient had a temperature of 98° F.; the urine was passed freely and the motions were normal. The eyes had a glassy appearance with the eyelids somewhat injected. He was pallid and had twitchings in the limbs at intervals all day. On the 14th the same symptoms continued, and there was a slight rose-colored rash in patches on the chest and the abdomen. On the 15th rash was very thick over the chest and the abomen. At 9 A.M. the child became extremely pallid with feeble pulse. He was ordered brandy, five drops every two hours. He had a second fainting attack about 11 A.M. His temperature was 98°. At 6 A.M. the rash on the chest and the abdomen was disappearing, but a slight rash developed on the back. He slept well. On the 16th the rash was very thick on the back and very slight on the hips, the neck, and the face, On the 17th the rash was almost gone. The eyelid injection and the glassy appearance of the eyes were rapidly disappearing. The child became convalescent from this date. The author had frequently used carbolic oil of this strength in circumcisions, but never before saw it induce symptoms of poisoning.

British Medical Journal, May 7, 1904.

Hæmoglobinuric Fever.—Ernest A. Boxer has seen distinct rigors and exacerbation of the black urine follow exhibition of five grains of quinine. His conviction is that quinine in black-water fever should be avoided—and nearly all drugs until we know of some really trustworthy specific, except the most simple and gentle purgatives, for example, calomel. As for food, he would almost recommend entire rectal feeding until the gastritis and intense biliousness is allayed. For patients in that state seemingly waste much, if not all, that is given them by the mouth, and time being of immense value, it is as well that absorption should be taking place continually. The writer feels that the secret of successful treatment of black-water fever lies not so much with physicians as such, as in skilful and tender nursing.

Treatment of Acne, Furunculosis, and Sycosis by Therapeutic Inoculations of Staphylococcus Vaccine.—A. E. Wright thinks that chronic staphylococcus invasions—in particular, furunculosis, sycosis, and acne—can be treated very effectively by inoculation of a staphylococcus vaccine. By this method the chemical machinery of the patient is induced to elaborate by its own efforts, the protective secretion which is required for the destruction of the invading bacteria. A vaccine of standardized strength must be employed. Before proceeding to reinoculation, the effect produced in each case upon the patient's blood by the previous inoculation must be measured to obtain the best results. It is advisable in obstinate cases to resort to a vaccine made with the particular strain of microorganism in which has acclimatized itself to grow in the patient's organism. In the cases here reported, clinical improvement invariably went hand in hand with improvement in the phagocytic power, and the negative phase which everywhere supervenes upon inoculation revealed itself to blood examination in the form of diminution of the phagocytic power and in some cases to clinical observation in the development of fresh pimples and boils. The writer concludes by saying that this transient and, clinically speaking, insignificant aggravation of the symptoms is full of instruction, inasmuch as it is indicative of the possibility of aggravating the patient's condition by the employment of excessive and too frequently repeated doses of vaccine.

Congenital Hour-glass Stomach.—W. F. Brook believes the following case of hour-glass stomach to be clearly one of congenital origin. The patient was a school teacher, aged fifty. She had been liable since girlhood to attacks of pain after food at no fixed interval, followed and relieved by vomiting. There was no history of hæmatemesis or melæna. The diagnosis lay between pyloric or hour-glass stenosis. The general enfeeblement was so marked that it was decided before operating to endeavor to pick up the strength by rectal feeding. Under this treatment the condition greatly improved for several days, till the seventh day, when the enemata were returned and vomiting recurred. At operation, the stomach which was unusually thin-walled, was found to be divided into two pouches by a narrow constriction. The peritoneum covering the isthmus was free from adhesions both in front and behind. It was transparent, glossy, and free from thickening. The omenta continuous with it, showed no sign of puckering. The pylorus and both pouches were free from thickening, and showed no external indication of chronic ulceration. Upon incising the isthmus, the mucous membrane showed no sign of cicatrix. The operation of gastroplasty was rapidly completed, but the patient died ten hours later. So narrow a constriction in the stomach must be a very vulnerable spot, so that it is not improbable that congenital hour-glass contraction may actually lead to ulceration, when traces of the latter, if found, would be liable to be wrongly interpreted as evidence of a pathological origin of the deformity.

Foreign Body Impacted for Seven Months in the Œsophagus.—Andrew Fullerton reports this case. The patient was a girl of seven years, and had swallowed a half penny seven months before admission to the hospital. The interesting points are as follows: The length of time since impaction, seven months. The absence of symptoms until three weeks before admission to the hospital, when ulceration of the œsophageal walls was evidently in progress. The situation of the coin, close to the arch of the aorta, into which ulceration would possibly have taken place, and in a position where the use of forceps might have been fatal. The method of dealing with the œsophageal wound: As it was in healthy structures, it was completely closed by a row of sutures in mucous membrane and a second row in the muscular walls. No tube was passed down the œsophagus to feed the patient. Rectal feeding was of doubtful effect. Soft, easily digested food was given at the end of the first week. The child made an excellent recovery.

Deutsche medizinische Wochenschrift, April 28, 1904.

Effects of the Röntgen and the Radium Rays on Cell Division.—Perthes claims that both of these rays have a well-marked inhibitive effect on division in both animal and plant cells. Observations made on the developing eggs of "ascaris" show that the *x*-rays exert a distinct harmful effect, independently of whether nuclear division has begun or not. The damage does not appear at once, but comes on later as cellular division proceeds, and is marked by an irregular course in the development and the production of abnormal end products. Analogous results were obtained when the radium rays were employed. Exposures of growing plant roots to the influence of both varieties of rays, also disclosed a marked inhibitive action on their growth. The author suggests that the effects are due in all probability to the production in the living cell by the rays of substances which damage the chromatin in the nucleus.

Berliner klinische Wochenschrift, April 25, 1904.

Zones of Hyperalgesia in the Neck after Bullet Wounds in the Head.—Milner believes that the principle elaborated by Head, whereby areas of analgesia in the skin may lead to the localization of disease processes in the internal organs, may also be applied with certain modifications to head injuries. He reports a case in which after the infliction of a bullet wound which involved the surface of the brain, but did not cause any marked general symptoms, localized areas of analgesia could be demonstrated in the neck. In this instance there was probably a direct irritation of the minute divisions of the sympathetic, either in the pia or the gray matter, and the extent of the hyperalgesic zone corresponded to the upper cervical segment, probably the second. Milner thinks that further observations in this field may demonstrate that accurate recognition of these dermal zones may facilitate the diagnosis in injuries of the brain, as by bullets, when the picture afforded by the *x*-rays is not sufficiently clear or conclusive.

Organotherapy in Pancreatic Disease.—Glaessner and Sigel have carefully studied the administration of various organic products in a s ries of cases in which pancreatic disease was suspected. The symptoms considered as characteristic were pancreatic colic and disturbances of metabolism and digestion, marked by the appearance of sugar in the urine, fatty stools, and insufficient absorption of albuminoid substances. They found that thyreoidin exerted an unfavorable influence on the symptoms. Pancreon had little effect on the nitrogen absorption and none at all on the resorption of the fat. The administration of pancreatin, however, produced an increase in the nitrogen resorption from 52 per cent. to 56 per cent., and of the fat from 41 per cent. to 68 per cent. The most favorable effects were found when large doses of the alkaline carbonates were given with the pancreatin, although the alkali alone was not followed by any marked increase. Pancreatin and sodium bicarbonate seemed to be the best combination.

Effect of the Application of Cold on the Heart Action.—W. Krebs has made some very careful observations in various diseased conditions, in order to determine the truth of the almost universally accepted dictum that cold acts as a sedative to cardiac action. He comes to the conclusion that the application of cold in the cardiac region benefits a certain class of patients suffering from cardiac insufficiency, whether of a neurotic or organic nature. This is shown by an improvement in the pulse rate, a reduction in its frequency, and an increased arterial pressure. He considers that one of the most important factors in the attainment of a favorable result is the enforced quiet to which the patient is subjected. In other cases no results can be perceived of an objective character, and these cooling methods cannot compare in their effects with digitalis. The application of cold is agreeable to the patient, but equally good effects are produced in most cases by water of an indifferent temperature. Moreover the application of a certain amount of moderate pressure on the cardiac region also seems to relieve the patient to a more or less marked degree.

Münchener medizinische Wochenschrift, April 26, 1904.

Complications of Fractured Clavicle.—Meinhold comments on the fact that in this fracture there is rarely any damage done to the underlying nerve trunks and blood-vessels. He reports a case in which man sustained a fracture of the middle of the clavicle by direct violence. Healing did not take place promptly, and it became necessary to remove a fragment of bone which was penetrating the skin. The fragments then united with the formation of a large callus. About ten weeks after the injury and while indulging in some severe exercises, the arm suddenly became numb and pulseless. An exploratory operation showed that the fragments had slid one over the

other and had become united in this position. A large callus apparently pressed on the subclavian artery through the scalenus muscle, and the sudden cessation of pulse may be accounted by a spasmodic contraction of the walls of the vessel due to the prolonged previous pressure, aided by the severe exertion.

The Prognosis in Intestinal Sarcomata.—Steinthal believes that the prognosis in this condition is not so bad as formerly assumed. The disease is quite rare and but few cases have been reported. The author operated on two patients, one of whom presented a sarcoma of the jejunum, which necessitated extensive resection of the intestine, and the other a sarcoma of the ilium, for which about seven inches of gut was resected. Both of these patients were operated upon about four years ago and have since then remained free from recurrences. The variety of sarcoma has an important bearing on the prognosis. The spindle-celled sarcomata usually produce a constriction of the lumen of the gut and therefore lead to the production of clinical symptoms earlier than the round-celled or lymphoid sarcoma, for the latter are apt to be accompanied by a dilatation. Operation is therefore undertaken at an earlier period in the former than in the latter class of cases.

Action of Fluorescent Substances on Diphtheria and Tetanus Toxin.—Tappeiner and Jodlbauer have supplemented their observations on the photodynamic effects of fluorescent substances on infusoria and enzymes, by experiments on bacterial toxins. They conclude that the practical application of their findings in therapeusis depends on two points of view. It has been demonstrated that the effect of fluorescent substances depends on absorption and also that the light rays penetrate the tissues to an extent which depends on the extent of their wave lengths. It would seem, therefore, that those substances are to be preferred which are rendered fluorescent by rays made up of long wave lenghts, *i.e.* green, yellow, or red. Then, again, other things being equal, those substances would be most suitable which show a particular affinity for those organs in which the toxin has become fixed. Methylen blue, for example, would be most appropriate for tetanus toxin, because, as Ehrlich has shown, this substance has a particular affinity for nerve tissue, and it is here that the tetanus toxin is localized. It also remains to be seen whether the substance when taken up into the tissues can only be excited to fluorescence as long as it remains in solution in the tissue fluids, or whether this continues when it has become fixed in the tissue. This opens a field for extended research.

French and Italian Journals.

Sudden Death in Chorea.—Barié observes that rapid or sudden death in chorea, even uncomplicated, is not very rare. Statistics give $2\frac{1}{6}$ per cent. of deaths in simple chorea. Generally nothing especial is discovered at autopsy and the fatal issue is unexplained; but in complicated chorea the mechanism of death is often very simple, being due to heart lesions, embolism, apoplexy, etc.—*Le Bulletin Médical*, April 23, 1904.

Syphilitic Origin of Appendicitis.—Faucher, in making statistics of cases in which syphilis has preceded other maladies, has found that out of 32 cases of appendicitis 29 developed in syphilitics. Of patients over 30 years, 4 were men, all of whom had had syphilis; 5 were women, 1 a syphilitic, while the husbands of 3 admitted syphilis. The author says that appendicitis occurs especially in cases of acquired syphilis. Of those under 30 years, there were 23 cases, 21 being hereditary syphilitics. In 2 instances there were 2 children in the same family. The writer has given specific treatment but once, and then without result. He considers appendicitis as a quaternary manifestation of syphilis, a form of parasyphilis.—*La Presse Médicale*, April 20, 1904.

Imperforation of the Hymen.—L. Laroyenne reports the following case. The patient was a girl of seventeen years. She had never menstruated. For fifteen days she had complained of vague pains, headache, and lumbar pain which had not hindered her from doing her housework. But for two days the pain had been very severe and she had found it impossible to urinate. Examination revealed an imperforate condition of the hymen, which bulged out, was red, tense, and fluctuating. The hypogastrium was distended and painful on palpation. The temperature was above normal. The hymen was incised with a thermocautery without anæsthesia. Pus was evacuated in the quantity of five or six hundred grams, containing no clots. The vagina was found to be distended. There was a condition of pyocolpos without pyometria. The temperature fell and the patient has continued in good health. Two months later menstruation began to appear for the first time. Bacteriological examination of the pus revealed small diplococci, some streptococci in short chains. Staphylococci were also obtained.—*Annales de Gynécologie et d'Obstétrique*, April, 1904.

Aneurysm of the Aorta Complicated with Addison's Disease.—Ducos relates this case. The beginning of the trouble was noticed four years ago. The patient suffered with asthenia, gastrointestinal disorders, lumbar pains; the characteristic tinting of the skin became very marked. At the first examination the abdominal aorta was found to be hard and dilated, but no other signs of aneurysm appeared. The patient was given adrenal medication with remissions. About six months later, after the strain of vomiting, there was a sharp pain in the epigastrium, followed by fainting. The tumor appeared about the size of a fist. The tumor persisted for about a month when hæmatemesis and melæna occurred; ice, both internally and externally, was applied and a hypodermic of ergotine was given. The symptoms subsided. There were two recurrences of hemorrhage, the latter being followed by death. Autopsy revealed a communication between the duodenum and the aneurysmal pocket. Microscopical examination of the suprarenal bodies showed nothing of special interest, and the histological examination has not yet been reported.—*Journal de Médecine de Bordeaux*, May 1, 1904.

A Case of Aneurysm Localized in the Arch of the Aorta.—V. Maragliano describes a case of aneurysm of the arch of the aorta, in which the diagnosis was made by the use of the *x*-rays. He considers radioscopy the best method for the diagnosis of such troubles. The patient was forty-one years of age. The beginning of the disease was rather sudden, coming on with cough. Five months before the patient was seen by the author. There was also loss of voice and pain in the right interscapular region. Later there were added to the symptoms a pronounced sense of suffocation when lying on the right side, and a characteristic harsh and prolonged murmur. On inspection the manubrium sterni was more prominent than normal, especially to the right. In the second intercostal space, on the right, along the margin of the sternum, was to be seen a rhythmical pulsation extending over the entire clavi-pectoral region. Percussion gave a marked hyperresonance over the manubrium and along the sternal margin. On auscultation the first sound was prolonged, the second increased in intensity. The left radical pulse was weaker than the right. Laryngoscopic examination showed that the left vocal cord was contracted. The radioscopic examination showed on the level of the second and third intercostal spaces, in a plane parallel with the middle plane of the body, a pulsating mass, which seemed to be deeply situated. It had a width of 11 centimeters. The patient died suddenly after a severe attack of coughing.—*Annali di Elettricità Medica e Terapia Fisica*, March, 1904.

Two Observations of Congenital Hydronephrosis in Young Infants.—Rabot and J. Bertier state that of all the different types of hydronephrosis, that of congenital origin, developing slowly during childhood and adolescence, is the least understood. Two cases have recently come under their notice. The first patient was a boy two years old, who entered the hospital on account of diphtheria. The urine was thick with albumin. The child died, and autopsy was performed. The two ureters were much distended, filled with urine, and of the size of the middle finger. They were perfectly permeable, and the bladder was healthy. Both ureteral openings into the bladder were very small and scarcely admitted a fine needle, and the urine passed drop by drop very slowly when it was forced from above. There were no traces of any inflammatory process. The kidneys themselves were apparently equal and normal. On incision, the parenchyma was seen to be diminished in thickness, while the calices and pelvis were distended. But the distention was much less in proportion to that of the ureters. The second patient was a boy of eighteen months, admitted to the hospital for measles with a severe laryngitis. The family history was negative, and the child had been healthy up to the present illness. Intubation was performed. During the twenty hours that the child was in the hospital, it passed urine only once. There were no signs of bronchopneumonia. There was no apparent disturbance aside from measles of a severe form, complicated by non-diphtheritic laryngitis. At autopsy, as soon as the abdomen was opened, both ureters were found to be very large, the left especially, and filled with urine. The ureters were bosselated. Dilation alternately with constriction. The kidneys appeared to be totally different. The left was hypertrophied almost to the size of an adult organ. On the right, the kidney was atrophied and was about the size of a little finger. The bladder was normal in size, but its walls were a little hypertrophied. On incision, the left kidney showed calices and pelvis somewhat dilated, while the right showed very advanced renal atrophy. The writer believes that the frequency of congenital hydronephrosis is greater than has been hitherto supposed. The treatment is surgical, various methods being employed; nephrectomy, nephrotomy, and conservative operations such as punctures.—*Lyon Médical*, May 1, 1904.

Society Reports.

THE NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, Held April 21, 1904.

ANDREW H. SMITH, M.D., IN THE CHAIR.

THIS meeting was held under the auspices of the Section on Laryngology and Rhinology.

Presentation of Portrait of the Late Dr. Joseph O'Dwyer.—Dr. WM. P. NORTHRUP committed to the keeping of the president and trustees of the Academy of Medicine, in behalf of the following-named members of the Medical Board of the New York Foundling Hospital the portrait of the late Dr. Joseph O'Dwyer: Drs. J. Appel, President; T. Halsted Myers, Secretary; Thomas Darlington, Health Officer of the City; John Reid, oldest associate member with Dr. O.Dwyer; L. E. Holt, R. G. Freeman, C. W. Cutler, J. A. Kenefick, and W. P. Northrup. Dr. Northrup said he had been commissioned by the above-named gentlemen to procure and present the best possible likeness of their distinguished colleague, Dr. O'Dwyer. There existed but one photographic negative, and whatever was accomplished had to be done from this. Though the negative was an excellent one, it had been retouched until the photographer's utmost desires were satisfied, and the result, an untouched photographic enlargement and carbon print, had met with the approval of the friends interested. The reproduction was unfading, the black printer's ink would last longer than the paper on which it was impressed. He regretted that it was impossible to obtain a good likeness in oil. The name and the two dates 1841-1898 had been clearly printed on the paper, and when the portrait would look down on successive generations of young men, who should come to see the honor list, no added comment would be needed. He hoped that the portrait would be accorded a place over the case of instruments containing Dr. O'Dwyer's inventions, as thus a life history would be represented, and we could say with pride that Dr. O'Dwyer had not been unrecognized by this Academy or unhonored by his friends. The speaker said that he was aware of the personal regard of the President and of every member of the Academy for the memory of Dr. O'Dwyer, and that this memorial tribute would be pleasing to everyone. He knew, that though Dr. O'Dwyer was the most modest and retiring of men, he would be pleased and comforted by the sympathy and kindly feeling of his friends thus expressed, although one would never have dared praise him to his face. He had once asked him to write out a sketch of his life, saying: 'It may be of interest to your boys, it may be of interest to the profession, it is of interest to me." Dr. O'Dwyer replied that all could be found in a certain directory which he named. When he opened the book, hoping to find "all," he found about ten lines in fine print telling when he was born, where educated, and that he was a member of the Widows and Orphans' Relief Society. . . . He asked that the President and members of the Academy consecrate a little space to the memory of Joseph O'Dwyer, for when the records of this Academy at the opening of another century were scanned no name would be more familiar, and the new fledged practitioner as he reverently moved from one portrait to another, and as he gazed upon those grave and noble faces would be himself ennobled and stimulated. He hoped that the portrait might survive accident and endure through all time as a tribute to that most modest, most honest, most useful of men, Joseph O'Dwyer.

The subject of the evening was tuberculosis of the upper respiratory tract.

Tuberculosis of the Nares.—Dr. CHARLES H. KNIGHT read this paper. He said that if the tubercle bacillus be the source or the vehicle of contagion, if it be capable of invading the organism through a break in the protecting epithelium, or even through a mucous membran still intact, the nasal fossæ might be expected to show the first evidences of its attack. Statistics proved that precisely the contrary was the fact. This immunity of the nasal mucosa was, perhaps, explained by the existence in the secretion of the Schneiderian membrane of some quality antagonistic to morbific germs. In fact, Herzog had only reported twenty cases of primary nasal tuberculosis. Secondary deposits were believed to be due to the conveyance of bacilli or toxins through the lymph channels, or less frequently by the blood current, to their point of development. The infrequency of generalization by way of the meninges was accounted for by the fact that the flow of lymph was *from* the brain *toward* the nasal cavities. Although all authorities were not in accord in regard to the bactericidal power of the nasal mucosa, still some explained the scarcity of bacteria in the nose by the irrigating effect of the secretions from the roof of the nasal cavities, by action of the cilia in repelling intruders, by the filtering function of the vibrissæ, and finally by the fact that ordinarily the inspired air contained very few pathogenic germs.

In regard to the coincidence of nasal atrophy and tuberculosis of the lungs a review of the subject made it reasonable to infer that the physical state predisposing to tuberculosis, or the resulting malnutrition, provoked the intranasal degeneration, rather than the reverse. The whole number of cases of primary nasal tuberculosis reported up to 1901 was 108, and a few have been since added.

Differential Diagnosis.—It was difficult to give a description of nasal tuberculosis that would enable one to identify it unfailingly. It was most likely to be confounded with lupus and syphilis. In distinction from lupus he relied chiefly upon the insensitiveness of the tuberculous nodules and the absence of a tendency to spontaneous repair after ulceration had been established. The serpiginous progress of the lupoid ulcer was diagnostic. Their resemblance, however, was often so striking as to justify the assumption that lupus was really a superficial form of tuberculosis. The practical identity of lupus from tuberculosis being admitted, the difference in their symptomatology being rather one of virulence or intensity, and the treatment of either being the same the question naturally arose why should they be continued to be regarded as independent diseases. From syphilis, with its proneness to simulate almost every other disease, and with its demands for a totally different mode of treatment, the diagnosis was more important and more difficult. Tuberculosis almost never involved the bony framework of the nose and but seldom the cartilage, but it would be unfortunate if we were forced to await such a differential sign as this, and often a tentative course of specific treatment would promptly cure a doubtful case.

He said it seemed proper to recognize in the nose as elsewhere two stages of tuberculosis, that of infiltration and that of ulceration. We met with the former as a diffuse condition or as a circumscribed tumor. Even a microscopical examination of the secretions or of the tissue itself might be inconclusive, as tubercle bacilli were sometimes absent from a lesion undoubtedly tuberculous, while they might be found in the air tract of a perfectly healthy individual. Ulceration was generally secondary to infiltration. The appearance of a typical tuberculous ulcer was usually pale, grayish, granular, with irregular "worm-eaten" borders, often thickened and dotted with translucent or opaque miliary tubercles, or it might be disguised by a profuse proliferation of exuberant granulations. Free hemorrhage was sometimes a marked symptom. It was more than likely that in every case there was a preliminary stage of infiltration, the ulcer resulting from disintegration of more or less extensive tuberculous foci.

Site.—As regards the site of nasal tuberculosis the septum, the inferior turbinated, and the middle turbinated was the order of frequency. The disease might start on the septum and creep across the floor of the nose to the turbinated, or it might invade the nose from the pharynx, or the palate, or again it might extend from the nose to the

lacrymal duct and the eye. As a rule the patient succumbed to general tuberculosis before extensive loss of tissue had been effected. There was general agreement that the prognosis, except in lupoid cases, was bad.

Treatment.—The treatment might be summed up as follows: The morbid deposit, if circumscribed and accessible, should be extirpated with curette and caustics, provided the general condition of the patient and the existence of active lesions in other regions of the body did not forbid interference. Phototherapy, of which they had had great expectations, had hitherto given no satisfactory results except in lupoid tuberculosis and in disease located near the *introitus nasi*. Although a rare disease, owing to various means of defence with which the nasal chambers were furnished, the obvious indication, especially as regards nurses and attendants upon tuberculous subjects, was to avoid causing an abrasion of the surface which might become an open door to the tubercle bacillus.

Tuberculosis of the Pharynx.—Dr. J. E. NEWCOMB discussed this phase of the subject and admitted the possibility of primary infection, though stating that most cases appeared as a late complication of lung disease while a few were seen in the earlier stages of acute general miliary tuberculosis. In view of the direct exposure of the pharynx to infection it was surprising that more pharyngeal lesions of this nature did not occur. It had been suggested that the pharynx enjoyed a special immunity, and that this resided in the scanty anastomosis between the external and internal lymphatics. There seemed no doubt that bacilli had been found able to penetrate intact epithelium, the resisting power of which was below par. It was possible that in the stage of mixed infection in lung disease the pus germs worked in between the epithelia, setting up minute abscesses, through which the bacilli entered.

In adults the involvement of the tonsils and cervical glands was secondary to the lung changes, but in children the reverse obtained. A possible source of infection was tuberculous disease of the spine. In men, the beard might become infected from the sputa and secondarily infect the pharynx. The sanitary suggestion from this fact was obvious.

When once infection had occurred we might have (1) a latent tuberculosis, (2) a typical infiltration and ulceration, and (3) the latter plus a systematic invasion. As to treatment of all these pharyngeal lesions, curettage, applications of silver solutions and various acids, and phototherapy were at our disposal.

As between lupus and tuberculosis, an initial febrile course, intense pain, an isolated origin on the posterior pharyngeal wall or other side, avoidance of the epiglottis (a favorite site of lupus), and a marked infiltration with a flattened surface, all indicated tuberculosis. The decision was strengthened by the occurrence of lung lesions and the absence of any old nasal scars.

From a review of the recent literature of the subject three things had impressed themselves on the writer. The first was that there was a form of the disease running an acute course in children and resembling on inspection the invasion of diphtheria. Examination of the deposit showed no bacilli, but lung disease coming on very shortly revealed the true nature of the malady. There were flaws in the arguments advanced to prove the tuberculous nature of these cases, for the bacteriological findings were incomplete. Granting that the initial lesion in the pharynx was tuberculous, it may have been secondary to some lesion in the chest, undiscoverable at first but becoming more evident under the general systemic deterioration.

The second fact worthy of note was that tuberculosis might cause perforation of either soft or hard palate. At least ten authentic cases were on record. Of this number eight were undoubtedly secondary to disease elsewhere. Examination of these cases showed yellowish polycyclic granulations on the palate with an adherent bloody covering, low borders, superficial, extremely sensitive, and surrounded by a reddish violet zone. The ulcerated areas gradually increased in depth until perforation resulted. They were generally of an irregular sinuous shape, and frequently appeared as fissures at the bottom of a narrow space. In this respect they offered a noticeable contrast to syphilitic perforations. Smaller openings might close up while larger ones called for surgery and prosthesis. A differential diagnosis was called for from (in addition to syphilis) congenital perforations, those due to trauma, scurvy and malignant disease and the "mal perforant buccal" of the French writers. The latter had been noted especially in tabes and pyorrhœa alveolaris. In the smaller cases the lesion might be the only one present, but in the larger the perforation was but one expression of the general malady.

The third fact worthy of emphasis referred to the so-called latent tuberculosis of the tonsils. The discussion on this topic dated back to 1884, but was revived by the appearance of the paper of Dieulafoy in 1895, who, from animal inoculation of preparations made from tonsils and adenoids, found that, judged by this test, one of every nine cases of apparent simple tonsillar hypertrophy and one of every five cases of apparently simple adenoids gave positive results. Lewin found that 5 per cent. of hyperplastic tonsils concealed tuberculous foci. This latent tuberculosis was almost impossible of clinical determination, as it occurred in tonsils of normal size as well as in enlarged organs. As to whether hyperplasis of the tonsils was brought about by some toxin influence was doubtful, but the latter could retard the normal involution of these organs.

The figures of the continental writers on this point had not been verified by the results of American investigators. While there was undoubtedly such a thing as latent tuberculosis of the tonsils, it was not as common as the earlier exponents of the theory would have us believe.

All the laryngologist could do in most cases was to heal up ulcerated areas, removing sometimes excess of infiltration. This made life more endurable though the patient steadily declined.

Laryngeal Tuberculosis.—Dr. J. W. GLEITSMANN read this paper.

Sources of Infection.—He said that after a review of the literature and experiments of investigators in regard to the source of infection of the larynx by the tubercle bacilli, it was evident that there was more than one source of infection. It had been shown that tuberculous invasion of the larynx through the epithelial structures was possible even when these were intact. Another mode of ingress was through surface erotions and through the floor of shallow ulcers. According to Horn, they might enter through the gland ducts, notably the subglottic region and the ventricles. A large number of recent writers considered the lymph vessels the principal channels of infection of the larynx.

Primary Laryngeal Tuberculosis.—The majority of laryngologists were averse to accepting its occurrence and believed that either a definable or latent tuberculous focus in the lungs coexisted or preceded the laryngeal lesion. He, however, believed in the occasional occurrence of primary laryngeal tuberculosis, though he did not consider it frequent. A complete absence of pulmonary tuberculosis must be established beyond a doubt. He did not see the rationale of the argument that there must be a complete absence of the disease in order to believe in the existence of another, viz., primary laryngeal tuberculosis. We saw tuberculosis without such in the lungs develop in other parts of the body, as the meninges, the genito-urinary tract, the peritoneal cavity, the bones, and with different sources of infection at work, and he did not see why the larynx should be exempt from yielding to such an exposure under favorable circumstances.

Early Symptoms.—Clinically, we were accustomed to recognize four forms of laryngeal tuberculosis: the miliary nodule, the infiltration, the ulceration and the tumor, but it was principally with the initial stage that we ought to interest ourselves because we could hope for better results than in a well-developed or far-advanced case. Anæmia of the palatine region was no longer considered a pathognostic sign of the disease, but we were inclined to consider it a resultant of deficient malnutrition. He said we sometimes saw hyperæmia of the faucial regions, and intense hyperæmias of the vocal cords long before any signs of tuberculosis, as infiltration or bulging of the posterior wall of the larynx appeared. A unilateral congestion was indicative of a grave lesion, although there were many puzzling exceptions. We occasionally noticed, among early symptoms, lessened sensibility and further changes of the voice not necessarily produced by congestion, but due to deficient function. Any proliferation, or thickening of the mucosa of the posterior wall, must receive immediate attention without waiting until the arytenoid region itself was infiltrated or the border of the epiglottis became thickened. Cauterization sometimes helped to determine the true nature of such fulness, and he had also employed silver nitrate fused on a probe; recurrence might also be had to the tuberculin test when an immediate decision was desired.

Pregnancy and Laryngeal Tuberculosis.—The consensus of opinion seemed to be that by far the greatest majority of women so afflicted died either during pregnancy or soon after delivery, although Seifert reported a case of a woman who had been treated for severe tuberculosis before a fourth pregnancy and who was discharged almost cured. When pregnant the fourth month she had similar laryngeal lesion and extensive infiltration of the upper left lobe. Under persevering treatment the laryngeal symptoms subsided and the doctor thought she could be considered cured. Such a happy issue was exceptional. Kuttner advocated expectancy in good condition of the patient with slight laryngeal affection, tracheotomy in infiltration, and if this had no effect, artificial abortion. Godkensen and Lewy considered artificial abortion justifiable in the first few months and in a condition of the larynx which otherwise offered a prospect of improvement without pregnancy.

Treatment.—Aside from general therapeutics and climate, the treatment could be considered under three headings—medicinal, surgical, and radiotherapy. Adrenalin, orthoform, and anæsthesin were valuable additions to our therapeutics. Formaldehyde, thiocol, guaiacol, eucalyptol, resorcin, and menthol were favorite remedies. He had used the latter combined with camphor and benzoinal as a spray or by laryngeal syringe with great satisfaction. He advocated the use of lactic acid for ulcerations but deprecated its use for infiltrations with intact mucosa. If milder means were of no avail a reasonable prospect of success could be expected from the different phenol preparations, viz., Monobromo—monochloroorthophenol, parachlorophenol, etc. The intravenous injection of cinnamic acid had been advised by Krause, who reported that not only superficial lesions of the mucosa healed without other remedies, but that medical and surgical treatment gave quicker results. As to surgical treatment curettage or excision of tuberculous tissue had some justifiable objections, the chief one being that it was difficult if not impossible always to remove all the diseased parts. However, this failure was not of such vital importance in tuberculosis as in cancer, because tuberculosis, if properly handled, was more amenable to treatment and had a tendency to self-limitation. He said that we should guard against overzeal in operating and decide each case upon its merits. Although the enthusiasm for surgical treatment had decreased and the great expectations at its inception had not been realized, it was still to be adopted in suitable cases and retained its place as a therapeutic measure. In regard to radiopathy, he said that it did not admit of doubt that certain rays produced visible effects, as decrease of pain, improvement of cough, expectoration, ulcerations, and the general condition of the patient, but to his knowledge there was no authenticated complete cure by rays alone reported. This failure so far ought not to lessen our efforts to master these mysterious forces for the benefit of our patients.

Dr. Walter F. Chappell said he was glad to hear the gentlemen admit the possibility of a primary tuberculous infection of the upper air passages. Personally, he believed in it, for he had seen one case of primary tuberculosis of the tongue, one of the nasopharynx, one of the tonsil, and three of the larynx. Knowing that the tubercle bacilli could invade every part of the system, he said he could not understand why some believed primary infection of the upper air tract was impossible.

With regard to the treatment of tuberculosis of the upper air tract it had been his experience that not enough attention had been paid to climate. It should be born in mind that climates that were suitable for cases of pulmonary tuberculosis would not do for those suffering from laryngeal tuberculosis. In the early manifestations of laryngeal tuberculosis, without laryngeal ulcerations, or, if they were present, without being active, he advocated the cold dry climates; but, in the older cases with active ulcerations, he advocated the warm climates and lower altitudes.

In reference to the surgical treatment personally, he used the curette in but two classes of cases, *i.e.* when there was a great deal of hypertrophied tissue present to relieve the dyspnœa, and again when superficial ulcerations were present, but without producing any hemorrhage upon the surface. He wished to join with Dr. Gleitsmann in sounding a note of warning against the indiscriminate use of the curette in cases of laryngeal tuberculosis.

Dr. Wolff Freudenthal said that he had never seen a case of primary tuberculosis of the upper air tract, and he would not believe in the existence of these primary lesion unless proven by post mortem. The Schneiderian membrane came so readily in contact with the oxygen of the air that the tubercle bacilli, which may have gained a lodgement there, were destroyed. On this account he did not agree with the statement that there was so very great danger of infection by reason of people spitting upon the streets. Regarding primary infection of the pharynx, he did not doubt but that this could occur through the lymphatic ring, and he wished that his colleagues would pay more attention to this fact. It had been his experience that women with tuberculosis of the upper air passages, and who were pregnant, invariably died. In such instances the interruption of the pregnancy was advocated.

In the treatment of tuberculosis of the upper air tract, he said that his results from the use of an emulsion of lactic acid and orthoform had been remarkable, and that he could relieve these patients in from 50 to 60 per cent. of the cases. In the Montefiore Home this application had relieved those patients when the use of lactic acic had failed to give relief. He used a great deal of the high-frequency current, although he believed the ray and light treatment yet to be in the experimental stage. He now only used the curette for two reasons, viz., when dysphasia was present and when the disease could not be removed otherwise. Tuberculous lesion of the lower part of the epiglottis could not be readily reached and removal of the epiglottis helped. He could not understand how scraping the ulcerations, as done by Dr. Chappell, could possibly have any valuable therapeutic effect. He emphasized the importance of giving Nature a chance to cure these patients by placing these ulcerations as much as possible at rest, and giving the patients a chance to eat and swallow.

Dr. S. A. Knopf referred to the value of prophylaxis in the treatment of these cases of laryngeal tuberculosis. Keeping the mouth shut and the voice quiet was very important and should be insisted upon. A great deal could

: done by proper hygienic and dietetic treatment besides s topical and surgical treatment in cases of laryngeal iberculosis. Although he recognized the value of the nlight and air when long enough in contact with the ibercle bacilli, he could not agree with Dr. Freudenthal at spitting upon the street was not very dangerous.

Dr. GLEITSMANN closed the discussion.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON MEDICINE.

Stated Meeting, Held April 19, 1904.

DR. CHARLES H. LEWIS, CHAIRMAN.

lyxœdema, with Exhibition of Patient.—Dr. H. S. PATERSON presented a boy, sixteen years old, who had been nder observation since March 22, 1904. As long as he ould remember, he had a swelling in the region of the thyid which was composed of two lateral lobes the size of an gg on either side of the midline and joined by a central nnecting portion. Two years ago he was sent to the resbyterian Hospital and was there from October, 1901, ntil January, 1902. On admission he was described as eing well nourished and not anæmic. The impression revailed among the men of the house staff that he was uffering from imperfect thyroid function. Previous to is admission to the hospital he had been treated at Bellevue Dispensary, and thought he was given thyroid. In October, 1901, he was operated upon by Dr. McCosh, the isthmus and lower part of the left lobe being spared. The pathologist reported adenoma and very little thyroid tissue. The wound healed up kindly. When he was discharged he was told to take thyroid. Although his statements as to his growth previous to operation are not of value, he was sure he had not grown since. He was an office boy in a brokerage office and did his work intelligently.

For several days previous to his admission to the Hudson Street Dispensary he had been constipated and had had abdominal pain. The physical examination was negative. He was anæmic in appearance; his face was puffy, nose broad, and there was a distinct longitudinal puffy fold under both lower eyelids. The hair was normal, the skin rough, especially over the abdomen and chest, the pelvis was small, and there was no pubic hair, but the testicles were well-developed. Over the situation of the thyroid there was a curved scar with the convexity downward, six or seven inches in length. The patient was given thyroid extract two and a half grains three times a day after meals. On March 26 his face was not so swollen and was less tense. The urine was negative and there was no mucin. Blood examination showed the red cells 4,100,000, the leucocytes 12,000, and hæmoglobin 73 per cent. (Sahli apparatus). The differential blood count of 300 leucocytes showed polynuclears 41 per cent., lymphocytes 54⅔ per cent., eosinophiles 4 per cent., megalocytes ⅓ per cent. On April 2, condition about the same as on March 26. The differential blood count of 300 leucocytes showed polynuclears 37 per cent., lymphocytes 59 per cent., eosinophiles 2⅔ per cent., basophiles ⅔ per cent., and large mononuclears ⅔ per cent. On April 10, red cells were 4,200,000, leucocytes 9,000, and hæmoglobin 80 per cent. The differential count of 300 leucocytes showed the polynuclears 43⅔ per cent., lymphocytes 51⅓ per cent., eosinophiles 2⅔ per cent., and basophiles 2 per cent. On April 16, the face appeared to be thinner, especially under the left eye. The differential count of 300 leucocytes showed polynuclears 54⅔ per cent., lymphocytes 40⅔ per cent., eosinophiles 3 per cent., transitionals 1 per cent., and basophiles ⅔ per cent.

The previous history, with the distinct change in the patient's condition since he had been under observation and under the thyroid treatment, showed that evidently there had been an insufficient thyroid function. Dr. Patterson said that, as a rule, people were inclined to think that those who were afflicted with myxœdema had associated with it marked mental obtuseness, but this was not the case at all in this patient. To him, one of the most interesting features in the case was the blood picture, although he recognized the fact that a 300 leucocyte count was not conclusive, although it was suggestive.

Dr. W. B. NOYES said that the mental condition of the patient depended upon the time of life the myxœdema began. In the case of cretins there was no mental development until they were cured, or else it was very slow improvement, leaving them semi-imbeciles. In a case reported by the speaker in 1896, in which a child who had begun to develope cretinism at the end of the first year and after some months, presented all the typical symptoms of that condition, treatment by thyroid extract had produced prompt and remarkable results in removing all symptoms of a myxœdematous nature, and had moreover produced an increase of height of eight inches in two months. For a year the mental development seemed to progress with the physical, but never reached the normal. The symptoms of cretinism were absolutely under the control of the thyroid extract, but the brain was not. It was not impossible that the congenital deficiency in the thyroid gland and congenital mal-development of the brain existed together. The fact remains that in this case, which excited much interest in the profession as one of the earliest and most successful of the cases of sporadic cretinism treated by the thyroid extract, was not cured mentally, but remained a backward or defective child intellectually.

Tabes Dorsalis with Early Appearance of Charcot Joint.—Dr. WILLIAM B. NOYES showed skiagraphs illustrating an early arthropathy in a case of tabes, referred to his clinic in the Demilt Dispensary from the Hudson Street Hospital. The patient had sought surgical treatment for a sinus under the ball of the big toe of the right foot, and for some obscure symptoms in the joint which were not causing him any special inconvenience. He complained of no symptoms subjective or objective except sudden attacks of pain in his lower extremities and occasional attacks of vomiting. His gait was normal except when he closed his eyes, when moderate ataxia was shown. His eyes were normal and no change of reflex excitability to light or accommodation was elicited. The only sensory changes found by careful examination was a moderate amount of anæsthesia of the feet, and delayed sensation to pin prick. He could not always differentiate a hot from a cold test-tube. The knee-jerks were lost and there was a diminution of muscular tone in the legs. There was slight ataxia of the arms when his eyes were closed. No abnormal mental, or bulbar symptoms were noticable. The first metatarsal-phalangeal joint was somewhat enlarged with an abnormally free range of motion, but no pain. He presented a half-healed perforating ulcer of the foot which was directly under the diseased joint. This sinus healed up in a few weeks under simple surgical treatment, but the joint remained unchanged, and one of the smaller phalangeal joints became somewhat affected. An *x*-ray photograph taken by Dr. Edward F. Killbane revealed an interesting state of affairs. The right foot showed a moderate swelling around the big toe; the first phalangeal bone was about three-quarters of an inch shorter than the corresponding bone of the other foot, and thickened at the central articular surface; considerable osteoporosis was shown. The metatarsal bone was elongated about the same amount, and showed considerable hyperplastic bone formation. Idiopathic, trophic changes in these two bones might have explained this, partly rarifying and partly proliferative, but the more probable explanation was a fracture of the first phalangeal bone with healing with a pseudo-articulation, and an ankylosis of the short central fragment to the metatarsal bone. Such fractures in early cases of tabes are fairly frequent, are not felt by the patient, and the lesion may be healed with enormous development of callus or the joint may become disorgan-

ized from the presence of the fragments of bone. This type of arthropathy secondary to fracture, is one of the commonest sources of tabetic arthropathies. Another method is also illustrated by the case reported, and that is by means of some infection introduced by a perforating ulcer of the foot. In this patient, as in most of these cases, the primary seat of the trouble is a corn on the sole of the foot, which becomes irritated, and suppuration takes place in the subcutaneous tissues, all of which is unfelt by the patient. A sloughing occurs, and in the low vitality of the tissues, perforation to the nearest joint is frequent and a disorganization of the joint occurs. The third method of producing a Charcot joint is illustrated by the general loss of tone in the muscles and joints of a tabetic. The loss of knee-jerk, which may frequently be noted in normal subjects in a tabetic, is associated with a general loss of tone, and a marked relaxation of ligaments and structures around a joint. Any slight traumatism may thus result in damage that would not affect the joint of a normal man. The anæsthesia of the joint surface makes these arthropathies painless, and no opportunity is given them to recover by ordinary methods of rest and protection. Such perforating ulcers are seen frequently in general paresis, when the changes in the spinal cord and nerves are similar to tabes, and also in diabetes and alcoholism which also present some of the same pathological changes in the nervous system.

Typhoid Fever with Repeated Chills.—Dr. JOHN HOWLAND reported the case of a man, thirty years old, who was admitted to St. Vincent's Hospital in July, 1903. His family history was good. He had never been seriously ill before. The present illness began one week before admission with general weakness, loss of appetite, and vertigo. Bowels were regular and stools normal. He had been three days in bed. On admission his temperature was 103.8, pulse 100, and respirations 30. The heart and lungs were normal. The spleen was palpable, and the abdomen had the typical rose-colored spots scattered over it. The urine contained indican. The Widal reaction, 1:50, was present. The usual treatment for typhoid fever was given and, during the first week, nothing of note happened, the temperature running from 102.5 to 104.5 and the pulse was of good quality. On the 10th day after admission the temperature was 101, and it remained low for three days. On the 20th day of the disease there was a severe chill lasting half an hour, and which was followed by a rise of temperature to 104.2. Nothing abnormal could be discovered beyond a trace of albumin and some granular casts in the urine. No malarial organisms could be found. Leucocytes numbered 7,600. On the 21st day another chill occurred, and these were repeated on the 23d, 24th, 26th, 29th, and between the 26th and 29th days the chills were repeated at frequent intervals. Two days later the temperature was nearly normal. Each of the chills was followed by a rise in the temperature. Following the chill on the 24th day the patient did not react well, and it was necessary to place the patient in the hot pack. On the 31st day there were two more chills and, during the next eight days, the patient ran an irregular temperature, usually under 100. On the 39th, 40th, 41st, 42d, 43d, and 44th days chills occurred which were followed by a temperature rise to 104 or over. Once it dropped to 96 in four hours. On the 41st day a femoral thrombus on the right side was noted, but it did not seem to complicate matters. Frequent examinations of the blood showed no leucocytosis. Blood cultures were taken and found to be negative. This patient had fourteen distinct chills, each followed by a rise in the temperature, and nothing could be found to account for them. Quinine in ten-grain doses three times a day was given without effect. None of the organs revealed anything abnormal, and the only thing that could be found which did not belong to the classical symptoms or signs of typhoid fever was the thrombus of the femoral on the right side, but this evidently had but little, if anything, to do with the occurrence of the chills. He reported the case as one of typhoid fever with repeated chills of unknown origin.

Dr. JAMES K. CROOK said that one seldom met with more than the initial chill in typhoid fever of classical type, and when they occurred during the disease one should be on the lookout for some beginning complication, or relapse. He referred to a case seen by him last year in which the woman presented all the typical signs and symptoms of typhoid fever up to the middle of the second week, when she had a marked chill, followed by a temperature of 107, which quickly subsided. The following day she had another chill, and these kept up at irregular intervals for two or three days. There was found an enormous leucocytosis. It was not until quite late in her history that she was found to be suffering from an enormous perituterine abscess. Dr. Crook asked Dr. Howland at what time the examination for the malarial organism was made.

Dr. RICHARD C. NEWTON of Montclair, N. J., asked Dr. Howland if sweating followed the chill and what was the line of diet. Years ago he had noted that certain alterations in the diet cause the recurrence of chills and fever.

Dr. J. FINLEY BELL of Englewood, N. J., reported the case of a young lady who had all the symptoms of typhoid fever in the second week, but who did not respond to the Widal reaction. On the twenty-fourth day of the disease she developed a chill. Repeated examinations of the blood showed a relative leucocytosis. He believed a leucocytosis of 10,000 to be only relative. He made four examinations of the blood and found some crescents. These crescents were only found when the blood was examined three hours before the advent of the chill; at other times they were not found.

Dr. CHARLES H. LEWIS referred to the importance of excluding, in such cases, malaria by giving quinine; then the blood should be carefully examined; then one should think of a possible sepsis or else a recrudescence of the trouble. The temperature chart shown was certainly not one of typhoid fever uncomplicated. He asked if a differential count had been made.

Dr. JOHN HOWLAND, in closing the discussion, said that chills followed the most pronounced sweating. The blood examinations were made before, during, and after the chills. No malarial organisms could be detected. Quinine had had no effect upon the temperature. The diet was mostly of milk, 32 to 48 ounces being given daily. When the temperature became normal the patient was given junket, toast, and scraped beef, but the diet seemed to have no effect upon the chills. No differential count was made and the blood examined showed no leucocytosis.

The Isle of Man as a Climatic Station.—Dr. JAMES K. CROOK read this paper As a result of a tour of European health resorts, in 1903, he stated that he was much surprised to observe the slight attention given to the picturesque little Isle of Man, by travellers from this side of the ocean. The ubiquitous Yankee tourist would be found during the vacation season in most of the queer nooks and corners of Europe, regardless apparently of any particular attractions possessed by many of them. Yet this romantic islet, so fraught with legiondary and historic interest, so easy of access, and withal forming peculiar climatic advantages, would appear to be a veritable *terra incognita* to our wandering fellow countrymen. The American tourist, he said, was all but unknown at the chief hotels on the island and some old Manxmen stated that they had never laid eyes on a Yankee. After referring to the geographical and topographical features, and briefly describing the fauna and flora, he stated that an important feature of the Isle of Man was the remarkable equability of the atmospheric temperature range. The annual variation was found to be less than that of any other health resort of the British archipelago. This smoothness of climatic condition could be aptly shown by a comparison with the annual variations observed in New York city. Here, he said, we had a mean annual temperature of slightly less than 52°F. The Manx yearly average was a little more than 49°F.

This showed only about 2° of difference in the yearly average. It would be observed, however, that while our summer range in New York was 71.5° that of Manxland was 57.1°, or about 14° less. The winter average in New York was 31.4° and that of the Isle of Man 45.1°, or about 16° higher. Our annual variation of over 40° is thus something like 26° more than that of the island. The equability of the Manx climate, as compared with that of points in nearly all of England, could be explained by the fact that the Irish Sea, which surrounded the island, was practically an inland body of salt water protected on all sides but the southwest, where it was co-terminous with the Atlantic Ocean. The air currents reaching the island from that direction were undoubtedly considerably tempered by the influence of the gulf stream. It was thus observed that the sea water immediately surrounding the Isle of Man was .7° F. warmer than that surrounding the British Islands generally, and .6° warmer than at Liverpool, only 82 miles distant. Dr. Crook thought that this equability of temperature constituted the one peculiar climatic advantage of the Isle of Man. Possibly, the sense of seclusion and isolation from the busy haunts of men, produced by the apparent remotiveness of the island from other bodies of land, would be found beneficial to persons of a neurotic temperament. Here was to be found a genuine mild, warm climate in the midst of a busy sea, but on firm ground and within easy call of great centers of population. Among other attractions of Manxland might be mentioned the pleasing and romantic scenery, the innumerable diversions at the choice of the seeker after health and recreation, and the astonishingly low rates demanded at the numerous clean and well-kept boarding houses and hotels.

Who Is Underfed?—Dr. HEINRICH STERN read this paper. He said, as long as in the lean the egress of material is made good by an ingress of assimilable material, there does not exist a condition of underfeeding. Excessive weight shows that the individual has been overfed. The appearance of the lean, he continued, may not always conform to our æsthetic sense; he may be affected by heat and cold, he may exhibit an irritable nature, but still may be healthy and may be enabled to stand many more trials than the overnourished. The dietary standards of the present day are entirely too high. He related some clinical observations in which the individuals were kept in nitrogen balance on as low a diet as twenty calories per day and kilo of body-weight. He said that a diet of from 35 to 50 calories, the usual amounts of food ingested, is entirely too large. He reached the conclusion that from 30 to 35 of total ingested calories and from 23 to 28 of "assimilable" calories are all that is needed by the individual employed in moderate labor for from eight to ten hours every day. He defines the underfed adult as one in whose economy a portion of the ingested substances is utilized perversely, one by whose excreta more nitrogenous material is carried from the organism in one week than has been introduced to it during the same period, and in whom the loss of absolute body-weight is always accompanied by decline of strength and resistance and occasionally by diminution of corporeal density.

Dr. E. E. SMITH said he was reminded of a case that he now had under observation. A man, past middle life, was on a peculiar dietary, eating practically no starch and but very little fat except what was contained incidently in lean meat. He had two eggs in the morning, lean meat with spinach at noon, and lean meat with spinach, or some other vegetable, at night. In making his calculations he found that this represented 15 calories per kilogram of body-weight. The patient had lost during the past year 7 kilograms. Dr. Smith still had this patient under observation and was trying to decide whether or not he was underfed. He said he was rather surprised at Dr. Stern's figures regarding the waist from course food.

Dr. NEWTON said that we should remember that different animals had different assimilative power, and this power varied with the ages of the animals. Thus, man could not assimilate food during the last third of his life as he could during the middle period. At this late period, the digestive apparatus becomes easily clogged, and one readily got into a state of "food-drunkenness." He believed that eight out of ten people over fifty years of age were in this condition.

Dr. Heinrich Stern closed the discussion.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Stated Meeting, Held April 18, 1904.

DR. ALEXANDER LAMBERT, CHAIRMAN.

Specimen of Gallstone.—Dr. FREDERICK HOLME WIGGIN presented an unusually large gallstone, the size of a leghorn egg. He removed this some time ago from a woman, sixty-four years old, who had been a sufferer from a chronic nephritis. She complained of severe abdominal pain and, on examination, no difficulty was experienced in making a diagnosis of gallstone, and he feared that the gallstone had ruptured through into the intestine. Upon operation he was surprised to find the gall-bladder was not inflamed, but the pain was due to an attack of appendicitis. He said it had been stated that elderly people were not so subject to attacks of appendicitis, but he had frequently met it in people over sixty years of age. Although the kidneys were in bad condition at the time of operation, no bad effects resulted, and this he believed to be due to the hypodermic injections of ergot the patient received prior to and during the operation.

The Management of Some Forms of Spasmodic Asthma.—Dr. THOMAS F. REILLY read this paper and referred first to the report of 2,130 cases by Brügelman of Wiesbaden, Prussia, who believed that the symptoms of asthma were due to disturbances of the sensory nervous system, set forth by one of the three states of the following general causes: (1) Traumatic; (2) toxic and (3) reflex, due to reflex irritation of the air tract in particular. Of this number 2,130, only seven were ascribed to cerebral traumatism, 222 to toxic conditions and the remainder to reflex irritations. Six hundred and sixty-five cases were referred to certain nasal points and 464 to certain points in the pharynx. He said the most frequent point at fault in the production of asthma was in the nose where the ethmoid nerve ran near the surface about at the junction of the bony and cartilaginous part of the nose. These attacks of asthma were very often relieved by producing a dryness or relaxation of the mucous membrane, such as could be done with stramonium. The stramonium salts all dried up the nasal chambers.

Dr. Reilly himself had seen half a dozen cases of asthma of paroxysmal character relieved remarkably by the use of suprarenal extract applied locally and administered internally. He had used this form of treatment in eleven cases with relief in all but two, and he believed this was a far better method of treatment than by the administration of the usual nauseating drugs. He advised the careful investigation as to the cause of the asthma, giving the suprarenal extract by spray and on cotton tampon and, finally, if necessary, morphine.

Dr. CHARLES E. QUIMBY protested against the use of the word "spasmodic" in the title of Dr. Reilly's paper, because this was not a spasmodic condition but a vasomotor disturbance, accompanied by the filling up of the blood-vessels of the lungs similar to the filling up of the blood-vessels of the turbinates when one had a severe cold. Traumatic cases were of such rarity that the causes, he believed, could be reduced to only the toxic and reflex. No attacks of asthma could be cured until one arrived at its cause and paid attention first to it. Dr. Quimby referred to hyperacidity of the stomach as one of the causes and reported a very rebellious case of asthma he had cured by the administration of bicarbonate of soda. One other case he cured by circumcision. He believed the percentage of

cases in which the reflex was contained within the nasal chambers were comparatively small. Very often the toxic causes were overlooked. He emphasized the importance of classifying the causes and, having determined the cause, remove it before we should expect to cure these cases.

Dr. FRANCIS J. QUINLAN emphasized the importance of thoroughly inspecting the nasopharynx in searching for the cause of asthma. He said nobody would question the vasomotor nervous system at fault in the production of this dread disease, and the upper part of the respiratory tract should always be examined carefully in each case. A few years ago writers on this subject did not speak of the nasal cavities at all in considering this disease, but started at the bronchial tubes; he wished it to be remembered that the nostrils and pharynx were part of the respiratory tract. He felt that, after his own experience, he must differ with Dr. Quimby when it was stated that many of the cases of asthma were not due to irritations about the nose. It was a regrettable fact that so many nauseating drugs were poured into the stomach, such as stramonium, iodide of potassium, etc., when the cause of the trouble could so often be found in the upper air tract and the asthma cured by attention to it.

Dr. L. F. BISHOP advocated the use of the suprarenal extract in the treatment of asthma, and gave illustrative cases to prove its value.

Ergot in Surgery.—Dr. ALFRED T. LIVINGSTON of Jamestown, N. Y., read this paper. In all operations it was desirable to produce an equable distribution of the blood in all parts of the body, and not to have an abnormal proportion in any one part, and this could be accomplished by the use of ergot which contracted the unstriated muscular fibers and toned up the blood-vessels. In fact, this drug contracted all relaxed unstriated muscular fibers. He first advocated the use of ergot in surgery in 1885. Until very lately his claims had received but little attention. The two conditions most dreaded by the surgeon were inflammation and shock. In inflammation there was an inefficient tone of the unstriated muscular fibers and here ergot was of great value. Shock could be largely prevented by the administration of ergot prior to, during, and after operations. It should be given hypodermically two or three days before the time of operation. Shock stimulated the vasomotor centers, made the circulation sluggish, the blood was not oxydized, and the body surface became blanched. This could be prevented by stimulating the non-striated muscular fibers by the use of ergot, making the heart's action better, the extremities warmer, and everything gave evidences of improved circulation. He said that Dr. Crile of Cleveland had referred to the uselessness of that general class of heart stimulants, such as strychnine, nitroglycerin, etc., and to the use of that powerful cardiac stimulant, adrenalin. The importance of equalizing the blood distribution to all parts of the body was emphasized, as also was the toning up of relaxed parts. By the use of ergot he said that anæsthesia could be continued for hours. It will greatly relieve the post-operative pain, the discomfort and nervousness. The danger of intestinal paresis, or paralysis of the muscular coat of the bowel, was much lessened by the use of ergot and the constant current. Post-operative delirium was largely controlled by the giving of ergot. Ergot, dry cupping, and the constant current he believed to be of value in appendicitis.

The most important use of ergot he said was in preparing the patient for operation, for the anæsthetic, and to prevent the undesirable sequelæ, such as shock, inflammation, post-operative pain, delirium, and other conditions.

Dr. FREDERICK HOLME WIGGIN wished to corroborate all that Dr. Livingston had stated, because he had used ergot for a long time, his attention being first called to its use in surgery by Dr. Livingston. When ergot was used there certainly was much less trouble in giving the anæsthetic and nausea seldom followed and the patients were less nervous. He believed ergot was particularly of value in abdominal work, controlling or limiting the peritonitis, and he cited many cases to illustrate its efficacy in surgery.

Dr. GEORGE TUCKER HARRISON gave enthusiastic praise of the efficacy of ergot, especially in surgery, and of its good in preventing intestinal paresis. By its use many patients might be saved who otherwise would have succumbed. Regarding what was said about the use of ergot in appendicitis he wished to be understood as placing appendicitis among surgical diseases, and the sooner that fact was recognized the better. Ergot seemed to limit the extent of peritonitis.

Dr. HERMANN GRAD said that ergot greatly lessened or prevented the nausa which followed the administration of an anæsthetic. Ergot should be given before the operation and, if the operation was a prolonged one, another dose should be given during the operation. When the patient was placed in bed other doses should be given every hour, if necessary, until the full physiological effect of the agent was obtained. He said that members of the Woman's Hospital Society had given this agent a trial with indifferent results, and he believed it had been given in sufficiently large doses.

In cases of post-operative pain a very small quantity of morphine would give relief to the pain if ergot had already been given; otherwise it would require large doses of morphine to control it.

Dr. LIVINGSTON closed the discussion.

Officers Elected.—The annual election resulted as follows: *President*, Dr. Francis J. Quinlan; *First Vice-President*, Dr. H. A. Dodin; *Second Vice-President*, Dr. S. Busby Allen; *Secretary*, Dr. W. R. Stone; *Corresponding Secretary*, Dr. J. J. Nutt; *Treasurer*, Dr. Charles E. Denison; *Member of Executive Committee for three years*, Dr. Alexander Lambert; *Member of Nominating Committee, Fifth District Branch*, Dr. Frederick W. Loughran. Sixty fellow and alternates were also elected to the State Association.

THE PITTSBURG ACADEMY OF MEDICINE.

At a scientific meeting, held March 29, 1904 (the president, Dr. Ewing W. Day in the chair), Dr. Johnston reported a case of a woman with tuberculosis. He was called to attend a hemorrhage from the lungs, but found on examination that the blood had been swallowed from the posterior nares. Adrenalin had stopped the hemorrhage, but later it recurred, and in spite of thorough packing of the nares by the interne, it again recurred and proved fatal. An autopsy was not permitted.

Dr. Boyce reported a case of epistaxis in which the nares were packed expertly by a leading rhinologist, yet the patient died. Then again he knew of other cases in which the nares were not packed and the patients recovered. He thought in many instances these cases were severe injections and the patients died not of hemorrhage but of toxæmia.

Dr. Litchfield reported a case of hereditary glycosuria. The family history of the patient revealed that a paternal aunt and a paternal grand aunt and grand uncle had died of diabetes.

Dr. Singley reported the occurrence of glycosuria in four members of one family. All are living at the present time.

Dr. Robert Milligan reported a case of hemorrhagic otitis.

Symposium on Typhoid Fever.—Dr. C. O. Goulding read a paper on "The Diagnosis of Typhoid Fever." He regards it as one of the most difficult of the infectious diseases to diagnose, as there is no single sign nor symptom pathognomonic of typhoid fever. He thinks the ideal sign of the disease would be the demonstration of the bacillus typhosus in the body of the patient, but owing to the difficulties and uncertainties attending such demonstration at present, it is not of great practical utility. He regards the bacteriological examination as confirmatory rather than diagnostic, and especially useful in irregular types of

the disease. He said that in his experience he found that the determining of the day of the fever had an important bearing on the prognosis and treatment. Among the later symptoms he regards the enlargement of the spleen as one of the most constant signs of typhoid fever, and has observed a relatively earlier and greater degree of enlargement in children than adults. He thinks absence of leucocytosis a valuable sign of typhoid fever. The Widal reaction he regards as confirmatory, as it often occurs too late for diagnostic purposes.

Dr. Lawrence Litchfield read a paper on "Treatment of Typhoid Fever."

Dr. Stuart Patterson, on the subject of Diet in Typhoid said: "We have, especially in the earlier stages, in typhoid fever, suspended or enfeebled digestion with anorexia, as the rule.

"At best, but a very small amount of the food taken is digested or absorbed. The residue acting as a culture medium in which all sorts of microorganisms develop; producing gases and poisons which give rise to the most distressing symptoms of the disease, as tympanites, high temperature, delirium, etc.

"Comparison of patients fed throughout the disease with those fasting, shows that those fed are *not* in any better physical condition, or any stronger at the beginning of convalescence, than are those fasting; while the fasting patients have *not* had the high temperature, delirium, or tympany we ordinarily see in this disease. There are rare exceptions. I am fully convinced that harm done by the residue far outweighs the good produced by the small amount of food used in these cases.

"My plan is to feed a patient when he is hungry and really wants food and *only* at such a time. Absolute fasting, except all the boiled water he will drink, is his rule. Has had a patient go twenty-two days without any nutriment whatsoever, and be apparently in as good condition as the average typhoid-fever patient who has been fed throughout the disease. He rarely had occasion to use alcohol. I begin feeding when the patient gets hungry and asks for food.

"Small amounts of sterilized milk, prepared in one of the many ways possible to suit the individual taste. Had always found a way to give milk to any patient no matter how much he objected that he 'could not take milk.' He gives enough after second or third day to satisfy hunger. Begin solid food or general diet when tongue is clean and temperature has been normal for about a week."

Dr. John W. Boyce said: In spite of the increase of our knowledge of the anatomy of typhoid, I cannot feel absolutely certain that we have made any advance in treatment. A careful reading of Nathan Smith's essay on typhoid fever convinces me that Dr. Smith was a fairly good practitioner, judged by our present-day standards. Dr. Smith wrote his essay about 1820; he treated his first case by hydropathy in 1798.

Since we have no remedy which is in any degree specific toward typhoid infection, it is unfortunate that we should ever adopt any measure solely because the patient has typhoid fever. But we all do form habits of this sort. As regards what is fashionable, I believe the pendulum has swung to the extreme point of over-feeding and over-stimulation. I cannot follow Dr. Patterson in his reasoning, nor do I starve my patients for the reasons he assigns. I starve them because I have seen much harm done by over-feeding and none, as yet, from under-feeding. My star case in this regard is a girl who for fifteen days took no single drop of either nourishment or alcohol; who lost flesh and strength less rapidly than I am accustomed to see in cases of similar severity; who never presented any abdominal or nervous symptom. In the handling of excessive tympanites, I find no single measure so effective as the interdiction of all nourishment for twenty-four or forty-eight hours, and a weak patient is stronger at the end of this period than at the beginning. As to the proper limits of therapeutic fasting, I have not yet satisfied myself. But the teaching that, in the acute infections, food must be given at three or four-hour intervals, to prevent the wasting of strength, is a present-day fad productive of much harm.

His preference when he feeds is for milk prepared with hydrochloric acid after the method of Dr. Boyce. He thinks forced feeding in convalescence a great mistake, and regards thorough mastication an essential when solid food is first allowed.

Dr. Silver reviewed the literature of the typhoid spine. He described the symptoms, pathology, diagnosis, prognosis, and treatment. As to treatment he thought the best method is rest in bed, especially the plaster-of-Paris bed.

Dr. Moyer said that while no one symptom was certain evidence of typhoid fever, he had come to rely much on two symptoms which he rarely failed to find: Splenic enlargement and the behavior of the capillary circulation when the skin of the abdomen was touched with the finger. He relied upon careful nursing and occasional symptomatic medication.

Dr. Johnston thought that excessive meteorism was best corrected by stopping the feeding, or using peptonized milk or changing to other goods as albumen water. While not a believer in antiseptic treatment, he had favorable results with acetozone; though in general he thought the less medication the better. In convalescence, he said urotropin was often useful, especially in those rare cases when cystitis developed. He thought that the recent tendency was to overfeed in typhoid fever, just as there is at present a tendency to overmedicate in pneumonia.

Dr. Douthett referred to recent observations in which a positive Widal was found in tropical diarrhœas, and various other diseases.

Dr. Small reported favorable results from the use of salol; since its use he had less meteorism. For diet he favored buttermilk.

Dr. Simonton said that a decrease in mononuclear leucocytes with an increase of polymorphonuclear leucocytes was often observed as a forerunner of a complication.

Dr. Anderson called attention to the statistics of Murchison—$2\frac{3}{10}$ per cent.—perforation. He said there seems to have been an increase since that time, as it occurs now in about 4 per cent. of cases. He thinks doubtless many cases in private practise are not promptly noted, while the earlier recognition in hospitals favored better results. He reported fifteen laparotomies for perforation, a perforation being found in twelve of the cases. He said the sooner the operation is done after the first pain the better.

Dr. J. Boggs mentioned several cases in which impacted fæces had been overlooked in typhoid fever.

Dr. Litchfield said that he favored a junket beaten up, as it cannot curd again. He said the mortality of the city of Pittsburg was 14 per cent. He suggested the subcutaneous use of olive oil when the patient was in extremis to furnish the calories to tide the patient over the critical point.

Dr. Goulding thought a supporting, symptomatic treatment and regimen were to be relied on. He said the condition in typhoid fever is similar to a swimmer being lost overboard from a ship: His only hope is that his strength will hold out until he is able to swim ashore. He thinks alcohol useful, though often used too freely.

Dr. Stuart Patterson said that feeding resolved itself into a question whether the portion of food not digested will do more harm than the digested portion will do good.

Medical Society of the State of California.

The thirty-fourth annual meeting of the Medical Society of the State of California was held at Paso Robles on April 19, 20, and 21, under the supervision of the President, Dr. H. Bert Ellis of Los Angeles. The meeting was largely attended, harmonious throughout and of more than ordinary scientific importance. Probably the most lasting impression left by the meeting was that made by the ad-

dress of the President, entitled "The Physician's Position in the Body Politic." The address was an able plea for greater activity in political affairs. The doctor should get into politics, he said, and go deeper into the affairs of the world, long enough at least to secure needed legislative enactments for the benefit of the profession. One of the measures upon which he laid the greatest stress was the improvement of the standard required of young men before they shall be permitted to enter upon the study of medicine. He showed that while 50 per cent. of the theological students and 20 per cent. of those entering upon the study of law possess academic degrees, only 7 per cent. of medical students are thus qualified. The standard should be raised.

Dr. Robert F. Rooney of Auburn delivered the address on medicine, taking as his subject, "Preventive Medicine." He advocated among other things a more hygienic mode of life, remarking that it would be better for us to go back to the laws of Moses, live in tents and obey the rigid requirements that were placed upon the children of Israel. The importance of regarding malaria as a communicable disease, the pest of the fly, and the necessity of bacteriological institutions in every State supported by the State were other measures advocated by the speaker.

Dr. J. Henry Barbat delivered the address on surgery. His subject was "The Surgical Treatment of Chronic Dysentery." The essayist believed that medical treatment is not sufficient in most cases. He advocated cholostomy, followed, if necessary, by occlusion of the bowel and the establishment of an artificial anus. If the result of these measures is satisfactory, intestinal anastomosis can later be made. The cases reported demonstrated that under the skilful technique of the author, excellent results have been obtained.

"Medical Education and Legislation" was the general topic for consideration at the afternoon session. The report of the Committee was read by Dr. H. S. Orme of Los Angeles. He regarded the present standard of education in california as satisfactory, but advocated more rigid measures of examination of candidates for the study of medicine. The test should be placed in the hands of the State Board of Medical Examiners instead of leaving it with the schools. The subject of reciprocity between State boards was recommended for discussion at the next meeting of the American Medical Association.

Dr. W. S. Thorne of San Francisco read the next paper, "Some Reflections on State Examining Boards." He also presented the report of the State Board of Examiners for the past year. The discussion was opened by Dr. Dudley Tait, president of the board. The discussion that followed his opening remarks was the most energetic display of oratory during the entire session. Adverse criticisms were numerous, and directed for the most part against the president of the board. But the end was peaceful and Dr. Tait remains a member of the Board.

Section on Nervous and Mental Diseases.—Dr. J. W. Robertson read a paper on "The Legal Responsibility of Medical Experts." It was an exceedingly complete review of the duties of medical expert witnesses, the character of the cases they encounter and the crimes which justify the plea of insanity. An appendix of the cases governing medicolegal questions as decided by the Supreme Court of California was presented at the close.

Section on Hygiene, Sanitation, and Climatology.—Under the title of "The Sanitary Needs of the State," Dr. N. K. Foster of Sacramento reviewed the sanitary laws, pointed out their defects, especially flagrant instances of their violation, and urged the importance of complete harmony between physicians, county societies and the State Board.

Chemistry and Physiology.—Two interesting papers constituted the work of this section. The subject of the first was, "Innervation of the Heart with Consideration of Cardiac Stimulants;" the essayist was Dr. O. O. Witherbee of Los Angeles. The other was read by Dr. Martin Fischer of Berkley, on "The Reversible Action of Enzymes."

Pathology and Bacteriology.—The work of this section was embodied in a paper on "A New Chromogenic Air Organism, Bacillus Cyaneus," by Dr. Ethel L. Leonard of Los Angeles.

Section on the Eye, Ear, Nose, and Throat.—Dr. Benj. F. Church of Los Angeles read a paper "Concerning the Varieties and Etiology of Glaucoma." He defined as glaucoma, all conditions of the eye in which there is an increased intraocular tension, and referred to the frequency of primary glaucoma. Inflammatory cases occur almost exclusively in persons between fifty and sixty years of age, but the chronic form is not so limited. The great importance of an early recognition of the disease was made the principal point.

Dr. W. H. Roberts of Pasadena followed with a paper on "The Pathology of Glaucoma." After reviewing the various theories regarding pathogenesis, the essayist reported fully upon his own investigations and pathological findings in eyes after removal.

Dr. A. B. McKee then read on the "Symptoms of Glaucoma," drawing a clear line of distinction between the general symptoms common to all cases and the predominant symptoms peculiar to different types of the disease.

At a subsequent meeting of the same section, several notable papers were read, among them, "The Tonsils as Portals of Infection," by M. W. Fredricks; "The Surgical Treatment of Chronic Tonsillitis," by Jas. A. Black, and the Post-operative Effects of Tonsillotomy," by Wm. B. Stephens, all of San Francisco.

Dr. E. W. Fleming of Los Angeles presented the "Early Clinical Manifestations of Tubercular Laryngitis," and Dr. Wm. E. Hibbard of Pasadena, "A Few Thoughts on Accessory Sinus Work."

Dr. Fred. Baker of San Diego then read a report of "Case Simulating Grave Mastoiditis. In one case of almost impossible diagnosis the blood count and widal test revealed the presence of typhoid fever. Much stress was laid upon the unreliability of severe mastoid symptoms in cases of serous otitis media complicated with grip of neuralgic tendency.

"The Importance of Chronic Otorrhœa as Viewed by Life Insurance Companies and the Medical Recruiting Officer" was presented by Dr. A. Barkan of San Francisco. Much favorable comment was elicited.

Dr. Kaspar Pischel of San Francisco then presented his original method of arresting hemorrhage after nose operations by means of the application of collodium over gauze, and demonstrated the process. The method has not only proved eminently successful, but has the advantage over others that it does away with the painful and unpleasant plugging of the nostrils.

Medicine and Therapeutics.—This section opened with the reading of three papers on the general subject of tuberculosis, the first by Dr. John C. King of Banning, entitled "Observations upon Sanatoria for Pulmonary Tuberculosis"; the second, by F. M. Pottenger of Los Angeles, on "The Rôle of the General Practitioner in the Prevention of Consumption," and the third, by Drs. George Blumer and A. J. Lartigau of San Francisco, on "Healed and Quiescent Pulmonary Tuberculosis with Remarks on Pleural Tuberculosis."

These were followed by a paper on "Malarial Nephritis," by Dr. Geo. F. Reinhardt of Berkley. The author believed that malarial nephritis is far more common than is supposed, owing to failure of recognition. He thought that 3 per cent. of all cases of malaria have nephritis. By the proper administration of quinine the disease is arrested and the chronic form prevented.

"Concretio Pericardii Cum Corde, with Report of a Case," was the title of a paper by Dr. Geo. L. Cole of Los Angeles. After its reading, Dr. Harold P. Hill of San Francisco presented "Chronic Endocarditis, with the Report of a Case."

Dr. Geo. H. Evatis of Los Angeles then made a preliminary

ry report on illustrative cases of myelogenous leukæmia- ree case reports were presented. The first case had d and the findings at autopsy were briefly described. the other two, one had been symptomatically cured d the other has been much improved as a result of treat- nt with the *x*-ray. In addition, the paper presented a mmary of some of the recent work on the histogenesis the leucocytes, with especial references to the disease sented. Caution was urged lest temporary improve- nt be mistaken for cure.

The work of the section closed with the paper of Dr. J. Sanderson of San Francisco on "The Hydrotherapy Rheumatism."

Pediatrics.—This section was opened with a paper on he Complications and Sequelæ of Measles," by Dr. Maher of Oakland, and the discussion that followed s one of the most remarkable features of the meeting. e essayist laid particular stress upon the importance of ating the disease as one of the more serious maladies, n in the mild form which it often assumes on the Pacific st. He reviewed the more common of the grave com- ations and sequelæ and the causes which generally to them, emphasizing the frequency with which measles followed by whooping cough and tuberculosis. The ations of the disease to bronchopneumonia, laryngitis, trointestinal disturbances, conjunctivities, otitis media, locarditis, and syphilis were spoken of and an outline he author's treatment was presented.

Dr. Hubert N. Rowell of Berkley then read on "Neuras- nia in Childhood." He said that it is more frequent an is generally believed. He recited the many causes, editary and acquired, that lead to it, and closed with eview of the treatment by means of rest, electricity, ssage, forced feeding, hydrotherapeutics, and par- ularly through attention to the psychical features of e disease, removing the feelings of fear and creating one elf-sufficiency.

A paper on "Vaccination," by Dr. Edw. von Adelung of kland, owing to the lateness of the hour, had to be read y title, and the session was closed by the paper of Dr. C. H. Pahl of Los Angeles, on "Congenital Dislocation the Hip." The discussion that followed was spirited d remarkable for the fact that the speakers from San ncisco were as emphatic in their denunciation of the renz method as those from Los Angeles were in their pport of it. The opinions in both instances were based on local results of the operation.

Genitourinary Diseases.—The leading papers in this sec- on were those of Dr. Granville MacGowan of Los Angeles "Surgical Interference for the Relief of Tuberculosis the Bladder;" Dr. Dudley Tait of San Francisco, "A ntribution to the Study of Varicocele;" and Drs. M. rotoszyner and W. P. Willard, or San Francisco, on Aseptic Catheterization of the Urinary Passages."

The Section on Cutaneous Diseases embraced four papers interest. They were, "Iodopin in Skin Diseases, with port of Cases," by Dr. Ralph Williams of Los Angeles; Adrenalin in Diseases of the Skin," by Dr. Granville acGowan of Los Angeles; "Syphilis from the Stand- int of the General Practitioner," by Dr. Geo. L. Cole of os Angeles, and "The Report of a Case of Scleroderma iffusa and Sclerodactylia; Its Clinical Aspect, Treat- ent, Post-mortem Findings and Histopathology," by r. Alfred B. Grosse of San Francisco.

Surgery and Anatomy.—Dr. Emmett Rixford of San rancisco read on "Inflammation of the Appendices piploicæ." In reporting two cases, he referred to the obably greater frequency of diverticula than has been cognized, their causes, greater frequency in the pelvic lon than elsewhere, and the evil results that may arise om the occurrence of inflammation in them.

Dr. A. W. Morton of San Francisco read on "The Con- rvative Treatment of Acute Appendicitis." This was llowed by a paper by Dr. Wallace I. Terry of San Fran- sco, on "The Treatment of Cases of Acute Suppurative Appendicitis by the Oschner Method." A third paper on the same general subject was read by Dr. C. Van Zwalenburg of Riverside, the title being "Appendicitis: Some Points in Its Diagnosis and Treatment from the Viewpoint that Its Cause Is a Strangulation Produced by Distention behind a Ball Valve." Each of these essayists spoke favorably of the Oschner method of treatment.

Dr. Charles D. Lockwood of Los Angeles followed with a paper on "Intestinal Obstruction, with Report of Three Unusual Cases." The first case was one of strangulated diaphragmatic hernia induced by vomiting in the course of acute appendicitis; Case 2, adherent Meckel's diverticulum associated with acute appendicitis, and Case 3, obstruction due to a peritoneal band, with unusual features.

Dr. James T. Watkins of San Francisco then read on "Some Mechanical Aspects of Scoliosis and Demonstrated Wullstein's Apparatus for Overcoming These Difficulties.' Two papers were presented by title by Dr. Claire W. Murphy of Los Angeles, one on "Echinococcus of the Liver with Report of a Case," the other on "The Surgical Anatomy of the Inguinal Canal."

"Ureterocystotomy" was the title of a paper, with report of a case by Dr. J. Henry Barbat of San Francisco. The history of the operation from its first trial by Tauffer in 1877 to the present, in all 120 times, was reviewed, with the causes which lead to the necessity of its performance, its technique and explanation of the author's method.

Obstetrics and Gynecology.—The former of these subjects was confined to two papers of interest, the former by Dr. Henry Gibbons, Jr., of San Francisco, on "The Second and Fourth Positions of the Vertex." The subject was fully presented, with tabular exhibits of the frequency of the positions according to various authors from Baudeloque and Naegele down, along with the methods of recognition and management.

Dr. Charlotte J. Baker of San Diego presented the other paper, on "The Diagnosis and Management of Transverse Presentation in the Later Months of Pregnancy." She stated that about one in two hundred presentations is transverse. Textbooks lay too little stress upon the importance of early recognition of the condition, yet it can generally be recognized as early as the seventh month. When early recognized it can be rectified before labor has commenced, in many cases, and all difficulty and danger obviated. The method of diagnosis and treatment were fully discussed.

Two papers were presented in gynecology. The first was entitled "Some Remarks on Hysterectomy, with Appended Report of One Hundred Cases," by Dr. W. W. Beckett of Los Angeles; the second was on "Uterosacral Ligaments and Their Relation to the General Pelvic Conditions, of Which Retroversion Is the Chief Symptom," by Dr. W. Francis B. Wakefield of San Francisco.

The next annual meeting of the society is to be held at Riverside.

The election of officers resulted in the selection of Dr. Frank Adams, president, Philip Mills Jones, secretary.

The society was reorganized and a new constitution was adopted. This was essentially the form proposed by the American Medical Association, and required the making of but very few changes in the old constitution.

Subconjunctival Injections of Alcohol.—Dr. Peschel has injected alcohol in doses of 1 c.cm. 15 per cent. solution since 1896 with very beneficial results. A mild œdema generally follows the injection, but ophthalmological examination shows that there is no intraocular or optic nerve œdema. He states that alcohol has remarkable disinfecting properties when it comes into contact with infectious material in the tissues in the wet state. The cases thus treated successfully include acute ulcerative keratitis, lime burn of cornea, serpiginous ulcer with hypopion, trachomatous keratitis, primary keratitis, and corneal abscess with anterior synechia.—*American Journal of Ophthalmology.*

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending May 14, 1904:

	Cases.	Deaths.
Measles	1516	45
Diphtheria and croup	389	51
Scarlet fever	363	...
Smallpox	2	...
Varicella	113	...
Tuberculosis	426	172
Typhoid fever	28	10
Cerebrospinal meningitis	...	97

Double Parasitic Monster.—Jagot reports this case. The patient was a young man of nineteen years, the fifth child of a woman who had previously given birth to two still-born monsters. There were in the family two other monsters, besides. This boy had been born at term. His health was good. Near the ziphoid region was a parasite composed of two arms and two legs, united by muscle and skin. The genital organs of the parasite were fairly well developed. The breasts were also present. There was only one nervous system for the two subjects. According to Saint-Hilaire's classification, this monster belongs to the second order, and is a double parasitic monster.—*La Médecine Moderne*, March 16, 1904.

Experiments and Observations on the Question of Intracranial Pressure.—Leonhardt made many observations on trephined pigeons and concludes that the views of Adamkiewicz are more trustworthy than the older theory of v. Bergmann. The latter believed that the amount of cerebrospinal fluid could not undergo fluctuations of volume and that any encroachment on the intracranial space would be followed by a rise in pressure of its contents which would finally exceed that of the blood-vessels, and that through obliteration of the capillaries the typical pressure symptoms would be the result of the anæmia. Adamkiewicz takes the standpoint that such a rise in tension of the cerebrospinal fluid cannot occur and that pressure symptoms are the result of irritation and not of increased intracranial pressure. The author's experiments uphold this theory and show that the cerebrospinal fluid can be taken up by the blood-vessels and lymphatics very rapidly. It is not the bulk of the fluid displaced which is of importance, but the rapidity with which the intracranial space is diminished.—*Deutsche Zeitschrift für Chirurgie*, Vol. 71, Nos. 1-2.

The Albuminous Bodies of Normal and Nephritic Urine.—Calvo has investigated the more complex albumins of the urine, especially with reference to the cold acetic acid reaction. He found that in every albuminous urine the acetic acid reaction could be produced by appropriate dilution. The amount of the body obtained in this way is variable and is often scanty in spite of high albumin content of the urine. In most cases the substance is principally euglobulin (and fibrinoglobulin), as well as serum albumin and pseudoglobulin which in some cases may predominate. That euglobulin as such is to be precipitated from urine by acetic acid is probable but not certain. Euglobulin (and fibrinoglobulin) is found in large amounts in febrile albuminuria and may even exceed the other albumins, while it is frequently present only in traces in interstitial nephritis. Pseudoglobulin shows reverse tendencies while the amount of serum albumin does not appear to be modified by the nature of the albuminuria. In some instances of subsiding nephritis the complete disappearance of pseudo-globulin was observed. The author was also able to corroborate Mörner's statement, which seems to have attracted but little attention, to the effect that after dialyzing the specimen an albumin reaction may be obtained from all normal urines. He differs from Mörner, however, in considering the body present not serum albumin but euglobulin (and fibrinoglobulin).—*Zeitschrift für klinische Medizin*, Vol. 51, No. 6, 1904.

Should It Be a Fixed Rule Always to Use Antiseptics on Our Hands?—E. M. Brown believes that in many cases it is safer to depend upon mechanical cleansing than to use antiseptics. Various investigations have proved that none of the methods of sterilization now in use can be absolutely depended upon. As to mercuric bichloride the writer states that it not only lacks penetrating effect, but it also has the property of forming an inert albuminate on the skin. Potassium permanganate and oxalic acid, chlorinated lime and sodium carbonate all present similar objections. They are very irritating to the skin of most people; they decrease the resistance of the tissues; and the false sense of security after their use makes them distinctly harmful. The most rational way to treat hands, so the writer believes, is by mechanical cleansing: First, with soap and water, changing water, brushes, etc., very often; great care should be paid to the nails, spaces between the fingers, etc. After this washing, submersion for five to ten minutes in water as hot as can be borne is advised. This dilates the capillaries and excites secretion of the skin glands, so lessening subsequent secretion during operation. If anything is used after this, alcohol is advisable for its hardening effect upon the skin. During long operations the hands may be dipped or washed in hot water and again in alcohol.—*Northwest Medicine*.

Health Report.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, U. S. Marine Hospital Service, during the week ended May 14, 1904:

THE POST-GRADUATE STUDY OF MEDICINE.

BY D. B. ST. JOHN ROOSA, M.D., LL.D.,
NEW YORK.

THE immense enlargement of the field of medicine and surgery in consequence of the advancements that have been made in the last one hundred years, is that which makes it necessary for a graduate in medicine to continue to study his profession during his whole life. Even a thorough course in a medical college, and for two years afterward a membership of the house staff in a hospital, will not enable him to go on his way in practice, without any further instruction. This is the fundamental reason why post-graduate study of medicine is necessary, and why its importance has been so much increased in the last few years.

In the olden time, after rather a meagre course in a medical college, and, in exceptional cases, in this country, with a limited hospital experience, the practitioner of medicine was content to go through his life and get what further knowledge was necessary, from his own patients, by his own experience, aided here and there by consultations, by reading in his few hours of leisure, and by an occasional visit to the great city. Here he did not find the opportunities for instruction for which he had hoped. The college teaching of the great cities was still adapted for the undergraduate only, just as it was when he left to work his own way, in his own field. When he returned he got very little comfort on the benches of these colleges. He had outgrown the lectures. He made a few visits to hospitals, and saw operations in an amphitheater, which he never undertook to perform. These exhibitions were to be considered purely as intellectural treats. There was no such thing as any systematized courses for instruction in such specialities as the eye, the ear, the surgery of women, or any subject for which the general practitioner had found himself not sufficiently prepared by the ordinary lectures, and the few clinics of his college course. Medicine, from being a simple profession, with very careful observation of symptoms, good and successful treatment of simple fractures, and with sad and unexpected results in operative surgery, by the invention of anæsthesia, and then the Pasteur discovery of fermentation as the origin of disease, with Lister's practical deductions, was transformed into a great science, reaching out toward prevention and cure in every possible direction. Every year after these days of discovery added something new which made the practice of medicine a great occupation.

The dawning of this day may be said to date back to the middle of the nineteenth century when, in 1846, Morton put a sponge, saturated with sulphuric ether, over the face of a patient in the amphitheater of the Massachusetts General Hospital—a patient from whom Dr. Warren removed a tumor, during which the subject of the operation felt absolutely no pain. Warren exclaimed, "This is no humbug, gentlemen." This was really the first public exhibition of the discovery of the principle of anæsthesia. From that beginning, followed by Pasteur's investigations, the development of medicine and surgery has followed. Young men began to go to Vienna and Berlin and Utrecht, as soon as the ophthalmoscope and laryngoscope were invented, and they found there the instruction that they desired. Few in number, they came back to our shores with their minds and hearts illuminated by the light of the new dawn. Here and there in New York, Philadelphia, and Boston, private courses were given in these few departments of medicine by these men. Soon the list of specialties for which expert knowledge was needed, began to be increased. Hardly a part of the human body but that advances were made in the matter of relief and cure. Marion Sims, with his demonstration of the curability of vesicovaginal fistulæ, in 1856, opened the way for a special hospital in New York, and for special instruction in gynecology.

The work of Ephraim McDowell, in the cabins of Tennessee, was followed by that of Spencer Wells, in London, and Homans, in Boston, and thus another field for special knowledge was opened. The ordinary all-round practitioner found himself overwhelmed by the waves of new knowledge that were sweeping over his intellectual coast. It became absolutely necessary that practitioners should prepare themselves for these great advances. The colleges were slow in this. Very reluctantly they increased somewhat the clinical instruction, very reluctantly they added hospitals to their lecture-rooms, and they utterly declined to give courses for graduates in medicine, except as they could be taken in conjunction with instruction to undergraduates. It was quite impossible for a tithe of the young men who wished further instruction than that which the college and hospital gave them, to go abroad. They did not know the language of Germany or France. The faculties were not prepared to receive them in Edinburgh or London. They were obliged to seek in their own neighboring cities for something to fill their eager desire to be able to accomplish in their hamlets, their villages, and their towns, what anæsthesia and the other discoveries had made it possible for them to do. It was not until 1882 that, after an unsuccessful attempt to engage the undergraduate colleges in the work, two post-graduate schools were opened in New York. They were immediately and have been continuously successful.

I think, in spite of the fact that the college term is now increased to four years, and there are many more hospitals in which service can be had, I have shown that post-graduate instruction is necessary—that this was a legitimate demand, made by the young and middle-aged practitioners, who came up from their fields of labor, anxious to secure larger opportunities and greater success by increased knowledge. The means of pursuing this instruction in this country, in New York, in Chicago, in Philadelphia, and in other cities are very well secured. They are simply the establishment of a school sufficiently large to contain a hospital, say of 200 beds, and a dispensary of illimitable capacity.

A man who has passed through a good medical

school and afterward spent a number of months in a hospital as an interne, is certainly fit for general practice, and yet, even in this statement, many qualifications should be made. If general practice is to include a care of the affections of the eye and ear, those of the throat, that can be seen only with the laryngoscope, and also an accurate knowledge of diseases of the nervous system, so as to be able to diagnosticate them, ability to care for the diseases peculiar to women, by surgical operations, this graduate will not even then be an expert in these and some other subjects. He will be strong in his knowledge of fevers, of obstetrics, of fractures and, to some extent, of operative surgery; he will have a considerable knowledge of pathological conditions, so that he can, in most cases, make an accurate post-mortem examination; he will be an all-round, competent practitioner, with a good mind, and will be able to supply his deficiencies by consultation and experience. But he is not fitted for exact and thorough personal care of such special cases as I have just mentioned. That knowledge can only be obtained by courses in post-graduate schools. Hence, their existence. They were well attended in Vienna long before they existed here. The very few isolated courses that could be found here and there, in New York, in widely separated places, given, for the most part, in auscultation, percussion, diseases of the eye, especially the use of the ophthalmoscope, were very unsatisfactory, since so much time was consumed in attending them. They were adapted for leisurely men, for undergraduates, or for that very small but existing class of graduates in medicine, who are always hovering around hospitals, and taking private courses, but being blessed with much money and discontented minds, never feel themselves able to begin. Consequently, before the foundation of post-graduate medical schools, a very few men out of the vast number who would have been glad to enjoy the privilege, went to Berlin and Vienna, and also to Paris. In Vienna, especially, the most ample opportunities were offered for graduates in medicine, who wished to continue their studies in specialties.

Anæsthesia and asepsis, as has been said, had begun to make operative surgery varied and successful, in contrast with its former limited and comparatively unsuccessful results, and Americans were found in goodly numbers at the surgical, dermatological, ophthalmical, and aural clinics, where excellent courses were given in the great general hospital of Vienna. But the obstacles to general attendance upon such courses here, finally induced a number of teachers in New York to establish post-graduate medical schools. They began in rather an humble way, in small situations, with rather scanty material, having no hospital, and a small dispensary. But the men who taught in these schools were enthusiastic and determined, and had had experience in teaching. What they offered to give was eagerly seized upon by the hungry and thirsty practitioners of the United States, and they came over from Canada in equal force, so that the managers of these institutions soon found that they were satisfying a real demand, and that they were justified in making great amplifications of their means and methods.

There was some surprise and little sympathy in the profession on the inauguration of post-graduate medical instruction in New York, and many did not hesitate to express the opinion that the enterprises would be short-lived. But they little knew how the great advances in medical science had stimulated the busy practitioners with aspirations to do good work, and that they were determined, if opportunity offered itself, to increase their knowledge, so that they might not neglect cases which they knew were treated by experts as an everyday matter, with complete success. There was an occasional smile at the great number of professors and instructors whose names appeared as the teachers in these two post-graduate medical schools, but this very smile was an indication of ignorance as to the necessities and nature of the kind of teaching for Doctors of Medicine, who wished to increase their knowledge. The much-used term of "enabling men to do things" explains very clearly just what post-graduate medical instruction is, and how it is conducted. For example, in diseases of the skin, the practitioner is brought up to the patient, he examines him, and in his own way notes the symptoms that he sees, and indicates, perhaps, what he might think to be proper treatment. This is followed by demonstrations by the Professor of any errors that may be made, and illustrations of the pathology of the conditions are passed around. In this way each man for himself has had an opportunity to make a study of one case at least, in the hour or two given to this exercise. And in ophthalmology, to take another instance, the doctor is given an instrument in his hand; he is taught how to hold it, how to cast the light upon the eye, so that he can see the reflection of the interior; he is sent with the patient, to find out for himself, how much this patient sees, to learn his visual power in a manner which is briefly told him. Then, to see if the defective vision depends upon disease, strictly speaking—that is to say, upon cataract, or a lesion of the vitreous humor or of the retina, or upon an optical condition. This he does for himself, and when we remember that when a man has mastered one case of eczema, and one case of compound hypermetropic astigmatism, he has mastered a very large number of cases of these conditions, so that in six weeks—much as has this short space of time been mistakenly held up as an opprobrium in the discussion of post-graduate medical schools by some of those undergraduate teachers who did not understand their aim and end—a man can actually learn how to use the ophthalmoscope, how to make a proper section for cataract, how to differentiate glaucoma, and how to tell at a close glance as to what form of disease of the skin or larynx, he is encountering. It is much better if he can stay twelve weeks, but many an American doctor has gone to Berlin and Vienna, and devoted a few weeks to one or two subjects, and has come back very well able to begin the practice in a specialty, provided he has first had the thorough preparation of graduation from a good college and a course in a general hospital.

The writer of this remembers a very interesting incident in relation with a professor of physiology, a man of renown and who had devoted his life up to middle-age to the active practice of medicine and surgery, for a few years, and then to experimenting and teaching physiology—the writer remembers assisting in teaching this professor to use the ophthalmoscope in an after-dinner séance, and with complete success, so easily does a well-trained mind and a hand used to manipulations continue the further investigations of the subjects cognate to, or rather the developments of what he has thoroughly studied in preceding years.

An affecting incident, as to the value of special instruction in a special department, occurred in one of the schools of New York within the last few months. A practitioner of medicine, witnessing and assisting in the operation for intubation of the larynx, exclaimed, with tears in his eyes, at the close of the hour, "If I had known how to do this, as I do now, my child would not have died."

Our post-graduate medical schools are, therefore, not to be discouraged because the courses are short. Nat-

urally, a physician may take as many courses as he pleases, and stay as long as his finances admit, but if he comes to a post-graduate school, and devotes himself to a small number of studies, say two or three, in six weeks he may achieve a great deal. If he does not wish to become an expert in any particular department—and by expert, I mean all that that term implies, able not only to diagnosticate serious conditions, but also to treat them—but is content to be a general practitioner, with a fair idea of what may be done in cases for which he does not find himself competent, he will even in six weeks, although I would not recommend such a use of time, acquire knowledge that will be of a great deal of importance to him in his lonely practice in the country. It will enable him sooner to recognize serious conditions which demand an expert. To give one more example of what may be done in a short post-graduate course, a practitioner of considerable experience, by spending six weeks in the laboratory, will be able to make very satisfactory analyses of urine. He will be able to examine the blood, and he will become so conversant with the microscope that he can, if time permits, in his own rooms at home, make many an instructive half-hour for himself in the investigation of healthy and morbid tissue.

But I am very happy to say that many of the men who come to the large cities for post-graduate instruction, spend three months instead of six weeks. Some even, stay the most or the whole of the academic year. It is observed that the number of those staying for longer periods, has increased since the schools were established. It cannot be denied that there are men who undertake post-graduate medical courses, who seem to have no higher ideal than to be able to say when they return to their homes and show by a certificate of attendance, that they have been to a post-graduate medical school. But these men are entirely the exception. After a good many years' experience in teaching, I can truly say that the eagerness of men coming to the New York schools, to learn what can be taught in special courses, on special subjects, is not to be surpassed in any country where I have seen doctors endeavoring to acquire more knowledge. Indeed, prominent medical officials of life insurance companies have stated that the knowledge of the medical practitioner in this country, as regards his capacity to determine the nature of a risk, has increased step by step, with the advance of the post-graduate medical schools.

The personality of the teacher, in one of these schools, is of the greatest importance. A superficial, indolent man who, in the dispensary wishes to get rid of his patients with a prescription, and with a scant attempt at a diagnosis, will be an egregious failure as a teacher. The men who come up for instruction soon recognize such a man, and keep a long way from his clinics, and, having been discovered by the students and by the governors of the school, he soon drops out. No uninteresting, humdrum instruction will be of any account in any properly conducted post-graduate school. In undergraduate colleges even the best men are obliged to study somewhat for the examination, and their efforts are either vigorous or indolent according to their knowledge as to what the examination is to be. There is no examination at the post-graduate medical schools, but a practitioner has in his mind what he can do in his practice remote from a large city, and remote, perhaps, from other practitioners, when he encounters a case such as he sees before him, and which he is able to examine for himself under the guidance of an expert. Such knowledge means more money for himself and his family, and it is one of the greatest stimulants to energy and industry. Much more than any diploma, does the case of someone that he knows in his town, whom he may now perhaps successfully treat, after his drilling with a dozen such cases, appear to him as a reward for the drudgery that he is undergoing in bending over the bed or the chair of the patients in the wards and dispensary rooms of the post-graduate school.

It has been sometimes thought that medical instruction would be made so thorough and would be so amplified, that post-graduate schools would become unnecessary. A little reflection will show that this view is entirely incorrect. The better the medical college, the longer the term in the hospitals, the more will certain practitioners wish to go where they can see cases massed in large numbers, of which at home they can see only a few. Post-graduate schools were born in the days when an epoch was made in medical and surgical knowledge, they will keep step with the advance in our professional knowledge, and steadily become more useful and necessary.

It has become simply impossible for any one man to master as an expert the various departments of medical practice. In the cities are found men who spend their lives in practising specialties. Whenever a general practitioner wishes to fit himself for a specialty, he must have recourse to post-graduate courses. And even if he is a tolerably well-fitted specialist, he finds in the greater experience and material of a large city, directed by an enthusiast, more opportunities in a few weeks, of increasing his knowledge, and consequently he will continue to come to attend some of the almost innumerable courses, ranging from auscultation to hydrotherapy, which are given in these schools.

The post-graduate schools in America have by no means diminished the importance of those of Vienna and Berlin. In Paris really no attempts have been made to furnish systematic medical instruction to graduates. While the undergraduate there may receive the most thorough training, and, if he know the French language, may nowhere in world be better fitted for practice, the one who goes there for special instruction in any of the specialties will find himself greatly embarrassed by the want of organization and, indeed, want of facilities, except in anatomy and ophthalmology, for advanced instruction. A professor in Paris not long since, advised a young graduate to return to New York if he wished special instruction in ophthalmology. In Edinburgh, also, excellent courses are given in anatomy and ophthalmology, and perhaps in one or two other departments, but here also, there is a failure of organization which renders it difficult for the graduate to obtain what he wishes, except in anatomy. In London there is absolutely no system of post-graduate medical instruction, worthy of the name. It is true, there is a college there, but no graduate with three or six months at his disposal would find it at all adequate for his purposes in any department of medicine or surgery. It is intended, rather, to be similar to the vacation course of Berlin and Vienna, which English practitioners may attend when they have leisure. Eminent men conduct some of the clinics and lectures, but the system in no way corresponds to that which obtains in New York and Vienna. There are always opportunities to study medicine and surgery in the great hospitals of London, and also to attach one's self to teachers in dermatology and ophthalmology. But here also, the opportunities are rather adapted to the expert who makes a flying visit, and who is anxious to know what his colleagues in the specialty are doing. As has been intimated, across the sea it is only in the German cities, chiefly in Berlin and Vienna, that the well-prepared graduate

of medicine, with a good knowledge of the German language, may find the opportunities for study in the laboratory, in the obstetric clinics, in pathology, in special or general surgery—in fact, in any department. Men thus fitted cannot fail to find themselves very much better equipped from a stay of a few months in either of these cities. Some of the younger teachers in New York are in the habit of going to Vienna and Berlin in the summer to take special courses, which are offered usually by the assistants, and not by the professors themselves. These courses are of great value.

What has been done in America has acted as a stimulant to the older medical centers, to induce even better organization there. Only very lately several articles on post-graduate medical instruction in America have been published in the weekly medical journals in Munich and Berlin, and have been received with the greatest interest by the best men in the profession. In the Kingdom of Prussia, since the foundation of the Friedrich-Wilhelm Haus, in Frankfort-on-the-Main, a systematic way of sending instructors and anatomical material to the various cities of the kingdom has been fairly established so that practitioners are not obliged to leave their homes during vacation time, but may receive advanced instruction under the direction of University teachers, in the hospitals of their own town. The German and Austrian Empires have for a long time maintained post-graduate medical schools for the medical officers of the army and navy, and the United States Government now also does something of the kind, but not in the efficient and thorough way that it is accomplished in New York, Philadelphia, and Chicago, where post-graduate plants are well established.

20 East Thirtieth Street.

THE ARMY MEDICAL SERVICE.

By EDWARD L. MUNSON, A.M., M.D.

CAPTAIN AND ASSISTANT SURGEON U. S. ARMY; ASSISTANT TO THE COMMISSIONER OF HEALTH, PHILIPPINE ISLANDS.

The Medical Department of the United States Army is composed of one surgeon-general with the rank of brigadier-general, eight assistant surgeons-general with the rank of colonel, twelve deputy surgeons-general with the rank of lieutenant-colonel, sixty surgeons with the rank of major, and two hundred and forty assistant surgeons, who have the rank of first lieutenant, mounted, for their first five years of service, and the rank of captain, mounted, thereafter, until promoted to the grade of major.

Each vacancy is filled by appointment by the President to the grade of assistant surgeon, with the rank of first lieutenant, after the applicant has passed a successful examination before an army medical examining board and has been recommended by the surgeon-general. Permission to appear before the board is obtained by letter to the Secretary of War. This letter must be in the handwriting of the applicant, giving the place and date of his birth and the place and State of which he is a permanent resident, and enclosing certificates, based on personal acquaintance, from at least two reputable persons as to his citizenship, character, and habits. To supplement these credentials, a personal investigation of the character, habits, antecedents, morals, and standing in his community is made with respect to the candidate, by medical officers or other officers of the army, acting under instructions from higher authority. No political influence in securing permission to appear as a candidate is necessary or desired, as appointments are made purely upon merit. The candidate must be a citizen of the United States, between twenty-two and twenty-nine years of age. He must be of sound health and good character, and a graduate of some reputable medical college, in evidence of which his diploma must be submitted to the examining board. The scope of the examination includes the moral, mental, and physical qualifications of the candidate and his general aptitude for the military service, and the board is explicitly directed to report unfavorably should it have a reasonable doubt of his efficiency in any of these particulars.

A thorough physical examination is first in order. This is necessary to ensure that the candidate is fully qualified to undergo the fatigue and hardships which are incident to field service, and to which the surgeon is exposed equally with all other officers. Such examination is also necessary to protect the retired list from being over-burdened by those having physical defects, which would render them liable to early breakdown and to become a charge upon the Government. Those who fall below sixty-four inches in height are not accepted. That a candidate should possess a well-developed physique, and a dignified carriage and presence, is, of course, desirable. Each candidate is required to certify that he labors under no mental or physical infirmity which can interfere with the efficient performance of any duty which may be required. Errors of refraction, when not excessive and not accompanied by ocular disease, and when correctable by appropriate glasses, are not causes for rejection.

The moral fitness of the candidate, together with his probable aptitude for the military service, is determined by the papers and other information in the possession of the board relative to the investigations made into his character, and by close personal scrutiny during the time in which he is undergoing examination. Any man whose previous record is not free from blemish, or who would appear not to be suited to the peculiar conditions of army service, is rejected.

The professional examinations are both written and oral, and include the subjects of anatomy, physiology, chemistry, hygiene, pathology and bacteriology, therapeutics and materia medica, surgery, practice of medicine, and obstetrics and the diseases of women and children. Usually one-half day is devoted to each subject, the candidate submitting a paper requiring about two hours to write, and then being carried rapidly over the subject by oral questions for about half an hour. These examinations are very searching, but are intended to be thoroughly fair and free from "catch questions." Especial proficiency in one or more subjects does not compensate for serious shortcomings in others, for the many-sided functions of an army medical officer require a thorough knowledge of all branches of a general medical education. The professional examination is concluded by a day's work at the bedside in clinical medicine and surgery, and operations and demonstrations are required to be performed by the candidate upon the cadaver.

This careful professional examination and freedom from politics lies at the foundation of the efficiency of the Army Medical Department, and has existed since the creation of an army by the second provincial Congress of Massachusetts Bay, in an act dated May 8, 1775, whereby medical officers of regiments could be appointed only "*Provided* they appear to be duly qualified on examination." That the examination thus required was not of a perfunctory nature may be gathered from an extract from a journal of the time. "On the day appointed, the medical candidates, sixteen in number, were summoned before the board for examination. This business occupied about four hours; the subjects were anatomy,

physiology, surgery, and medicine. . . . Six of our number were privately rejected as found disqualified. The examination was in a considerable degree close and severe, which occasioned not a little agitation in our ranks."

At present, examinations are held in Washington, San Francisco, and Manila. Eleven hundred and eighteen young physicians were ordered up for examination in the period 1889–1901, inclusive, and of this number one hundred and eighty-seven were found qualified. This proportion of successful candidates was unusually high because of a large number of young surgeons serving with troops under temporary contract, as a result of hostilities with Spain, in the Philippines and in China, who had already undergone a preliminary examination, and thus represented the better element of the original body of candidates. With such rigorous selection, the Army Medical Department may fairly claim to be a *corps d'élite*.

Hospital training and practical experience in the practice of medicine, surgery, and obstetrics are essential to candidates, who are expected to present evidence that they have had at least one year's hospital experience, or the equivalent of this in practice. Candidates are not now ordinarily examined except in professional subjects; though an examination may be required in history, arithmetic, geography, physics, and literature in the case of candidates showing deficiencies in their general education. As a matter of fact, men presenting such deficiencies will scarcely be able to attain the required average in their professional examination. Candidates claiming a special knowledge of languages, higher mathematics, and natural sciences are examined therein and given extra credits accordingly. An applicant failing in one examination is allowed a second trial, but not a third.

The promotion of an assistant surgeon to the rank of captain is contingent upon a satisfactory examination in the main subjects of a general medical education. and particularly with respect to recent advances in medical science. A part of this examination also relates to the functions of the surgeon as an officer of the military service. A similar examination must also be passed before promotion to the grade of major. These examinations serve as a stimulus to professional advancement, taking the place, in this respect, of the active competition existing in civil practice. That these examinations are severe is shown by the fact that a certain proportion of medical officers are turned back from time to time, losing thereby in respect to pay and promotion. Advancement to the grades of lieutenant-colonel and colonel takes place by seniority and without examination. The surgeon-general is selected by the President from the members of the department, usually those of higher rank and greater experience.

To each rank is attached a fixed annual salary, payable in monthly installments, and this is increased by 10 per cent. for each period of five years' service, until a maximum of 40 per cent. is attained. An assistant surgeon, on entrance, receives $1,600 per annum, or $133.33 monthly. At the end of five years he is promoted to captain and receives $2,000 a year, which, with a 10 per cent. service increase, is $2,200, or $183.33 monthly. After ten years service, this pay becomes $2,400 per annum for office with the rank of captain. The pay attached to the grade of major is $2,500, which, with 10 per cent. added for each five years of service, becomes $3,000 after ten years' service, $3,250 after fifteen years, and $3,500 after twenty years. The annual pay of lieutenant-colonel, colonel, and brigadier-general is $4,000, $4,500, and $5,500 respectively. In addition to the above amounts, all officers on duty outside the United States receive a further increase of 10 per cent. on their pay while so serving.

Medical officers are entitled to the privilege of retirement at any time for disability incurred in the line of duty, or after forty years' service. On attaining the age of sixty-four years, they are placed on the retired list by operation of law. Retired officers receive three-fourths the amount of their pay in effect at the time of their retirement; a sufficient income being thus provided for support in case of disability contracted in the service or for old age. In the case of a medical officer retired as a colonel, his retired pay would thus amount to $3,375 annually—which would be a fair interest on $75,000, or a greater sum than the average physician in civil life could hope to amass in a long life of professional activity. In case of death due to causes incident to the service, a pension is granted to the dependent members of the deceased officer's family. This pension in the case of an officer of the rank of lieutenant-colonel amounts to $360 annually, with $24 for each minor child. This sum, though small, is about the interest on a life insurance policy of $9,000.

In addition to the above pay, officers are furnished either with comfortable quarters or with a liberal money allowance in lieu thereof. No house rent has therefore to be paid by the medical officer. When travelling on duty, an officer receives mileage at seven cents per mile for the distance traveled. He is also entitled to transportation for professional books and papers and for a reasonable amount of baggage at Government expense. All medical officers are provided gratuitously with forage, stabling, and transportation for two horses owned and kept by them. Groceries and other articles may be purchased from the commissary, and fuel from the quartermaster's department, at wholesale cost price and less the usual retail dealers' profits. Books, instruments, and appliances are furnished by the Government for the use of medical officers in the performance of their duties.

Leave of absence on full pay is allowed at the rate of one month per year, and this may accumulate to a maximum of four months as a continuous leave. Beyond this, an officer may still be absent with permission on half pay. Absence from duty on account of sickness involves no loss of pay. From the above, it is seen that financial matters need not become a cause for anxiety to the army medical officer; his pay depending largely upon the grade held, and this in turn having a close relation to length of service.

The social side of army life should not be forgotten, as it forms a most pleasant feature of military service. The army officers of the line and staff are largely graduates of West Point, are men of education and refinement, and, as a whole, are gentlemen in the best sense of the word. The medical officer will find that his social status among them depends upon his own attributes and personality, and he will form many close companionships. In the civil society of the communities in which, or near which, the medical officer may serve, he will find that his commission as an officer gives ready entrance, where the same man, as a civilian, would be first subjected to a long period of probation. Physicians in civil life are more than kind to their confrères in the army, and go out of their way to show them every professional assistance and favor.

A fixed home is out of the question in the army, where all are subject to orders and must move about as the need of the service requires. Strong local affiliations cannot be maintained, and military service necessarily means an abrupt change in life,

associations, and previous surroundings. Wherever he goes, however, the medical officer will find some of his old army friends and will make many new ones. It is rare that domestic arrangements are interfered with; most officers are married and take their families with them nearly everywhere. In a few years' service, the medical officer sees much of the world and meets many people of affairs, all of which is a valuable education and has a strong broadening influence. To many the constant change of scene and surroundings is a great charm of military life.

Every facility is afforded to medical officers to keep in touch with medical progress. The young physician, on entrance, is usually given a course of five months' instruction at the Army Medical School, Washington, D. C. This course includes military medicine, military surgery, military hygiene and sanitary chemistry, clinical and sanitary microscopy, and a special course relating to the functions of the surgeon as a military officer. When medical officers with the rank of captain approach the period of their examination for promotion to a majority, they are usually assigned to duty as attending surgeons in large cities, so that they may become familiar with the practice of the leading physicians and surgeons of the country and may benefit from medical lectures, clinics, meetings of medical societies, etc. With the present policy of concentrating troops near large cities in the United States, medical officers have excellent opportunity to keep fully in touch with the professional progress of civilian physicians and surgeons. Each post hospital has a library of carefully selected medical works, usually one hundred and fifty or more in number. Twenty-five or more books are added yearly, and those which have become obsolete are called in and sold from time to time. In addition, sufficient copies of twenty-two representative medical journals are subscribed for by the surgeon-general's office, and are circulated for perusal and reference among the medical officers. The library of the surgeon-general's office, in Washington, is the largest medical library in the world, and contained on June 30, 1901, no less than 236,728 books, journals, theses, and pamphlets. Any special books desired by medical officers will be loaned from this library on request. The Army Medical Museum, under the same roof with the library, contained on the above date 34,988 specimens relating to medical science.

No better opportunity of winning a name in medical science is afforded anywhere than in the Government medical service. With a class of sound young men as patients, the field of practice in obstetrics, gynecology, chronic diseases, and the diseases of children and old age is necessarily restricted, and in the usual course of service the surgeon will scarcely find sufficient practical experience to develop into an expert along these lines. On the other hand, the opportunities for study in hygiene, bacteriology, pathology, the various branches of chemistry, and certain classes of diseases, especially those peculiar to the tropics, can scarcely be equalled under the best facilities of civil life.

Though work in the practice of medicine is thus somewhat limited in scope, it makes up in quantity what it loses in variety. Thus, in the year 1901 there were 232,080 admissions to sick report, of which number 19,703 were for injuries. While in time of peace there is a relatively small amount of surgery, in time of war the army medical officer does more surgery in a week than the average civil surgeon does in six months. There is a good deal of operating for appendicitis and the radical cure of hernia, both of which disabilities appear to be greatly favored by military conditions.

The field of experimental research is particularly attractive, and is one in which professional reputation is achieved much more readily than in general practice. Besides the opportunity, the medical officer has the time and money to engage in such work. His military duties are so systematized that he can do the maximum of work in the minimum of time, and thus has many hours which he can call his own. The use made of such spare time, in the army as in civil life, depends upon the individual. His work may be broken in upon from time to time, but if persisted in there is nothing more certain than that excellent results will be attained. As the medical officer is scarcely influenced by financial matters, he is not under the disadvantage under which the civilian physician usually labors—that of constantly being diverted from his chosen work by the necessity of bread-winning. Any special apparatus, laboratory equipment, books, or other facilities are gladly furnished by the medico-military authorities to those who give promise of being a credit to their profession and corps.

For the above reasons, army medical officers have long stood in the forefront of medical progress, and have been able to furnish representatives whose names have been famous the world over. Not to mention men still on the active list, it is sufficient to recall the classical work of Surgeon Beaumont on the physiology of digestion, that of Woodward and Otis on the military surgery of the Civil War, that of Billings in hygiene and medical literature, that of Sternberg in bacteriology, and that of Reed, who lately died in the knowledge that his researches into yellow fever have done more for mankind than anything since the days of Jenner.

Since the outbreak of the war with Spain, the Army Medical Department has well shown its capabilities. The report of the Army Commission which investigated typhoid fever in 1898, is classical; army medical officers have discovered the means of transmission of yellow fever and formulated measures which experience shows will stamp out the disease with absolute certainty; they have demonstrated that the fatal anæmia in Porto Rico, which killed thousands annually, is due to ankylostomiasis and can be cured with a dose of thymol; they have identified surra as the fatal horse disease in the Philippines and have shown it to be transmitted by a certain species of biting fly; they have investigated the animal parasites found in the Philippines; they have found that tropical dysentery is largely due to a specific bacillus; they have shown the previously unknown existence of Malta fever in Porto Rico and the Philippines; and they have added much to our knowledge of plague. Applying these results practically, the army medical officers in charge of health matters in Cuba reduced the death rate of Havana from 91.03 to 22.11 in four years, and in Manila from 46.50 to 22.17 in the same period, making the rates for these cities compare favorably with those of the most civilized communities on the globe. In three months' time, the Army Medical Department vaccinated the entire population of Porto Rico, numbering some nine hundred thousand souls, and stamped out smallpox where it had previously been endemo-epidemic. In the Philippines, their efforts largely protected the troops from cholera at a time when the natives of the vicinity, not under their control, were perishing by tens of thousands. In the coming work on the Panama Canal, the Army Medical Department will be in sanitary charge. With an abundance of able and willing men in its personnel, and with magnificent opportunities for experimental research and practical work along professional lines, the Army Medical

Department looks forward to the future, confident of fully maintaining its honorable record in the past.

THE NAVAL MEDICAL SERVICE.

By JOHN F. URIE, M.D.,
SURGEON, U.S. NAVY.

THE history of the early days of the medical corps of the navy is somewhat obscure, though practically since the establishment of a government in this country and the use of a naval force medical men have found occupation on board our vessels of war. In the records of naval affairs of the Revolution little more than mention is made of the ship surgeon and his mate, but enough is recorded to establish the fact that such grades were carried on the books of most of the ships that fought the fight of the colonies. That these people obtained a rich surgical experience the story of the naval engagements of that period gives ample proof; that they had no definite organization or standing is equally evident from the meager records. Though the surgeons were commissioned officers and their mates held warrants, they were apparently hired for the cruise of their vessel and were discharged upon its completion.

Not until the period just prior to the war of 1812 does it appear that a permanent list of medical officers was established. At that time, and from that time on, the records contain a list showing a varying number of surgeons and their mates in somewhat of a corps organization. This list may be considered as the beginning of the medical corps as an organized part of the navy, though it was not until 1842, at which time the bureau system of the Navy Department was inauguated, that the corps arrived at the dignity of having a medical officer at its head.

From that time to the present it has developed by means of the varying action of succeeding congresses, and in spite of the vicissitudes of the frequently changing naval policy until it has reached its present organization and standing, which, without exaggeration, may be stated as the high-water mark of its existence, and concerning which this paper has to deal.

As organized to-day the corps consists of about two hundred and twenty members, with provision of law enacted to bring the number up to 347. The law authorizing its increase, which went into effect on the 5th of March, 1903, provided that its accomplishment should be distributed over a period of six years, twenty-five appointments being allowed each calendar year.

The following table shows the grades, rank, and number in each grade of the corps as it will be at the end of 1908 under the present legal provisions:

NUMBER	GRADE	RANK	EQUIVALENT ARMY RANK
15	Medical director	Captain	Colonel
15	Medical inspector	Commander	Lieutenant-colonel
85	Surgeon	Lieutenant-com'd'r	Major
230	Passed assistant surgeon and assistant surgeon	Lieutenant	Captain
		Lieutenant, junior grade	First lieutenant

Two additional officers, one in the grade of medical director and one in that of surgeon, are borne on the list by congressional sanction as not in the line of promotion.

In addition to the above, a list of twenty-five numbers under the title of acting assistant surgeon, form part of the medical corps in the Navy Register. The members of this list are employed for temporary service only, and at the expiration of three years from the date of appointment sever their connection with the service. This grade has been revived from the provisions of an old law granting the President authority to appoint twenty-five acting assistant surgeons for temporary service, and has been utilized to meet the emergencies of an enlarged service awaiting the filling of the permanent corps up to its authorized strength.

One member of the corps is selected, usually from one of the two upper grades, for the position of surgeon-general and chief of the bureau of medicine and surgery and holds the rank of rear-admiral while in this office. This appointment is made by the President and holds for a period of four years, and is the highest official distinction to which a medical officer of the navy may aspire. Since the establishment of the office in 1842, there have been but seventeen medical officers who have been fortunate enough to receive this honor.

Appointments to the medical corps are made only in the lowest grade—that of assistant surgeon—and permission to appear before the boards for examination is obtained for the asking. Political or other influence has no weight in bringing about the issue of this permit, and the young medical graduate with no influence is given just as free an opportunity to show his fitness for a commission as one presenting the most powerful recommendations. It requires simply an application to the Secretary of the Navy for permission to appear before the Board of Examiners, accompanied by one or more letters from persons of standing, certifying to the moral character of the applicant and to his citizenship. The law requires, besides citizenship, that the applicant shall be not less than twenty-one and not more than thirty years of age, and shall demonstrate before the Board of Examiners his mental, moral, and professional fitness for appointment.

At the close of 1903 there was only one vacancy in the medical corps of the navy, but on the 1st of January, 1904, twenty-five new appointments became available by provision of the law of March 5, 1903, mentioned above, with twenty-five each succeeding year for four years. The vacancies from retirements, resignations, and deaths average about ten a year. There are assured, therefore, for the next five years about thirty-five appointments yearly.

The examinations required to demonstrate the fitness of applicants consist of a physical and professional and a collateral examination. The physical examination is thorough, and the candidate is required to certify on oath that, to the best of his knowledge, he is free from mental, physical, and constitutional defects. A standard of vision has been established, and candidates are required to have a visual range of $\frac{1}{20}$, Snellen, unaided by glasses and capable of correction to $\frac{20}{20}$ by lenses.

The professional examination, while covering the whole field of medical science, does not demand more of a candidate than he should have acquired from his collegiate training.

The following table shows the scope and value of the professional examination:

	WRITTEN QUESTIONS	PERCENTAGES REQUIRED
Anatomy (2) and physiology (1)	3	80
Surgery	3	80
Medicine	3	80
Pathology (1) and microscopy (1)	2	70
Obstetrics (1) and medical jurisprudence (1)	2	60
Materia medica and physiological action of drugs	2	80
Chemistry (2) and physics (1)	3	60
Hygiene (1) and quarantine (1)	2	80
General aptitude	..	80
Literary and scientific branches		80
Required aggregate		750

This is supplemented by a series of practical demonstrations of the candidate's acquirements in

bandaging, application of splints, operative work on the cadaver, clinical cases, uranalysis, practical microscopy, histology, pathology, bacteriology, and the recognition of surgical instruments. An oral examination in each branch covered by the written follows it. The questions asked in both the written and oral examinations are similar to those required by the best medical colleges in their examination for graduation. In the collateral examination the candidate is required to show what he has acquired from his general educational advantages, and not more is expected in this department than any well-equipped physician should possess. A knowledge of the grammatical use of the English language is essential, and arithmetic, geography (descriptive and physical), history, languages, general literature, physics, elementary botany, geology, and zoology comprise the subjects taken up in this division of the examination. Credit is given for a knowledge of languages and the sciences, but they are not essential. Deficiency in the common-school branches is, however, a cause for rejection, even though the candidate should meet the professional requirements of the examination.

There are two boards of examiners before which candidates may appear—one on the Pacific Coast, holding its sessions at the U. S. Naval Hospital, Mare Island, California, and the other on the Atlantic seaboard, with its examining rooms at the U. S. Naval Museum of Hygiene and Medical School, Washington, D. C. These boards are practically in continuous session throughout the year.

The young medical graduate, therefore, desiring to enter the medical service of the navy, being not over thirty years of age, has but to write a letter to the Secretary of the Navy asking for permission to be examined, accompanying his letter with testimonials as to moral character and citizenship, to be accorded that privilege. With the granting of this permission he will be told to communicate with the president of the Examining Board holding its session nearest his home to arrange for a date for the examination mutually agreeable. The examinations usually occupy about ten days and are of the character stated above.

This much the Government demands of aspirants for service in its naval medical corps. What does it offer in return? A candidate upon being accepted by the board is given the commission of an assistant surgeon in the navy with the rank of lieutenant, junior grade, by the President of the United States, and his appointment as such is confirmed by the Senate. This, in itself, may be considered in the light of an honor. A more practical emolument, however, is represented in the following:

PAY TABLE.

	AT SEA	ON SHORE	ALLOWANCES PER ANNUM*
Assistant surgeons, rank of lieutenant (junior grade)	$1,760.00	$1,496.00	$288.00
Passed assistant surgeons, rank of lieutenant	2,200.00	1,870.00	432.00
After five years in the service	2,400.00	2,040.00	432.00
After ten years in the service	2,600.00	2,210.00	432.00
Surgeons, rank of lieut.-commander	3,250.00	2,762.50	576.00
After ten years in the service	3,500.00	2,975.00	576.00
After fifteen years in the service	4,000.00	3,400.00	576.00
Medical inspectors, rank of comm'nd'r—			
After fifteen years in the service	4,500.00	3,825.00	720.00
Medical directors, rank of captain—			
After fifteen years in the service	5,500.00	5,500.00	720.00
Surgeon-general, rank of rear-admiral			

*Only when quarters are not furnished by the Government.
Eight cents per mile is the allowance when traveling under orders.

While on shore duty and when quarters are not furnished by the Government officers are allowed commutation therefor, which is represented in the column of allowances in the above table. On shore duty in foreign countries the shore pay of officers is augmented by an addition of 10 per cent.

By provision of law, assistant surgeons, at the end of three years' service, are entitled to promotion to the next higher grade—that of passed assistant surgeon—after qualifying by examination. The number in the upper grades being fixed, promotion into them depends upon the occurrence of vacancies by retirements, resignations, or deaths, and these vacancies are filled in the order of seniority. With each promotion a physical and professional examination is required by law. The total number of vacancies occurring in a year, with the number of the corps at 200, averages about ten. Promotion with an increase of a little over $400 a year in salary is assured at the end of three years' service, and every five years of service brings a slight increase of pay without promotion. Promotion thereafter is an uncertain quantity, depending somewhat upon retirements and casualties and somewhat upon the evolution of the navy as a whole. The junior surgeon of the list at the present time reached this grade in less than five years from the date of his entrance into the service. The senior surgeon was seventeen years in obtaining his full surgeoncy. The prospects for promotion, however, in the near future as indicated by the growth of the naval establishment already authorized, and that contemplated, seem to be very good.

The tenure of office in the medical corps is for life, unless sooner terminated by resignation, by disability not incurred in the line of duty, or by dismissal for misdemeanor.

At the age of sixty-two all officers of the navy are retired from active service with three-quarters of the full sea pay of the grade held by them at that time. Incapacitating disabilities contracted in the line of duty also entitle an officer to be placed on the roll of the retired list on three-quarters' pay.

What are the professional opportunities placed before young medical graduates looking for a settlement in life in the naval service? Pay and other emoluments count for something, but to most ambitious young men the chances of putting their professional education to the best advantages are of fully as much importance in the choice of a field of labor. It is the prevailing idea among members of the medical profession in civil life that the naval career offers little scope for the exercise of one's professional ability, and this, perhaps, in the main, has been true in times of peace in the past. In the future, however, with the rapidly growing naval establishment, the accession of territory by our Government outlying its continental limits, and the many new problems arising from new methods of warfare, the naval medical officer will find a larger field for the exercise of his professional knowledge. His duties to-day cover a wide range. The selection of the personnel in recruiting, its training in health, its care in sickness on shipboard and in hospital, and its protection against the inception of disease are the main responsibilities of the medical officer. Work in the administration of his department on ships, stations, and in hospitals, on boards of examiners for both mental and physical examinations, as instructors to the enlisted force in first-aid and emergency work, to the members of the hospital corps in their duties and drills, and to the younger members of the medical corps are other fields of occupation. The medical officer is at all times sanitary adviser of his commanding officer, whether on shipboard on shore stations, at home or abroad, in camp, or on expeditionary service.

To follow out the probable professional service of a medical officer after his acceptance of a commission, a casual sketch of his possible assignments may be of interest. Shortly after notifying

e department that he has taken the oath of office id accepted his commission he will receive orders some one of the fourteen naval hospitals. These spitals are situated at all the larger naval centers, z., Portsmouth, N. H.; Chelsea, Mass.; Newport, . I.; Brooklyn, N. Y.; Philadelphia, Pa.; Washgton, D. C.; Norfolk, Va.; Port Royal, S. C.; ensacola, Fla.; Mare Island, Cal., and Puget ound, Washington. There is also a naval hosital at Yokohama, Japan, and one each at Cavite, hilippine Islands, and Sitka, Alaska. These hositals vary in size and importance. The largest of iem—those at New York and Norfolk, having a apacity of 150 to 200 patients—are equipped nd maintained to meet the requirements of the ost advanced medical and surgical procedure. t these hospitals the medical novice is initiated nto the methods of naval customs and becomes acuainted with the requirements of hospital corps ffairs and training. He is required to remain on uty at one of these institutions until the beginning f the session of the Naval Medical School in Washgton, D. C.; about the 1st of October in each year. t this school, to which all newly-appointed medical fficers are ordered for instruction, he is trained in he application of his profession to the requirenents of naval life, in certain specialties of imortance to the intelligent performance of his future luties, and in the military features demanded by is career as a naval officer. This medical school is ssentially a post-graduate institution, and its course f instruction comprises the following subjects: nilitary medicine, military surgery, tropical medine, naval hygiene, its chemistry and biology, uarantine, manual of the sword, extracts from actics, hospital corps drill, instructions in signals, nd the duties of medical officers in administrative work in general. Bacteriology, blood examination, nd the study of parasites form very important branches of the laboratory courses, and are given n one of the most modern and fully equipped laboratories in this country. Five months are devoted to this school work, and after its completion the young medical officer is usually assigned to sea duty. Here his work again follows the line of advanced medical and surgical procedure. He is provided with the latest and best instruments of precision and operation, and is given every encouragement to make research and extend his knowledge of his profession. The most recently constructed battleships and large cruisers are equipped with hospital facilities equal to those found in our best organized smaller cities. Vessels of this type carry a crew of from 600 to 700 men, and for the care of the sick of this number the medical officer is furnished with a small hospital of from twelve to twenty-five beds, a small isolation compartment, a dispensary, and a modern operating room. These are equipped with every modern appliance for the prevention of disease, the care of the sick and wounded, for operative interference, and the prosecution of scientific investigation as far as practicable aboard ship.

Frequently in place of being assigned to a seagoing vessel, the young medical officer is detailed for duty in some one of the stations abroad. The navy has an important hospital at Yokohama, Japan, and one at Cavite, Philippine Islands, with another in process of construction at Canacao, Philippine Islands, this latter, when completed, to take the place of the one at Cavite. The Islands of Porto Rico and Guam give employment to a small number of medical officers, the different shore stations in the Philippines, with their force of marines, require the services of others, and the lately acquired stations in Cuba will soon call for others. The tour of sea duty usually occupies three years, at the expiration of which the officer is returned to his home and, when conditions permit, is given a leave of absence before being again assigned to duty. His next field of work is at some one of the many shore stations on either the Atlantic or the Pacific seaboard. At these stations he is called upon to perform the duties of physician and surgeon to the station, or those required in the examination of recruits, or the sanitary and emergency work in connection with the large manufacturing establishments at navy yards, or the manifold problems arising at the receiving and training stations. He may be fortunate enough to receive again an assignment to some one of the hospitals; this time in the more important duties of executive officer or senior assistant. The large supply depot at Brooklyn, N. Y., called the Naval Laboratory, requires the services of a small number of officers; the Bureau of Medicine and Surgery, the administration office of the Medical Department of the Navy, at Washington, gives employment to others; the examining boards for candidates for admission to the service, and the medical school offer most interesting occupation for still another number. Opportunities are frequently given for the attendance of medical officers upon the meetings of medical and other scientific societies, both at home and abroad, as the accredited representatives of the Navy Department and the Government, and it is the policy of the Bureau of Medicine and Surgery to encourage the attendance of officers on such gatherings whenever practicable. It was formerly the custom to give a certain amount of leave of absence to ambitious medical officers for the purpose of carrying on a line of study either at home or abroad, and when the number of the corps is increased sufficiently to warrant it, this custom will probably be renewed. The accession of new and outlying territory by our Government has opened up new fields of research in tropical medicine, and opportunities are given to medical officers to take every advantage of them. Occasionally an officer who finds ship life congenial can continue it while on shore service by obtaining an assignment to a receiving-ship. Here he has to care for a large number of recruits coming and going, and is employed in the selection of recruits from the raw material of civil life. Recruiting is also carried on in traveling parties which cover the whole territory of the United States. Occasionally opportunity occurs for medical officers to join scientific exploring parties as the medical officers of the expeditions. A medical officer of the navy is detailed for duty on the Fish Commission Ship *Albatross*, and one is at the head of the Department of Materia Medica at the Smithsonian Institute.

As his rank increases, the duties of a medical officer become more responsible and in keeping with his age and rank. From assistant on board a large vessel, or in charge of the department of a small vessel, he graduates by successive steps to the charge of the department of vessels of large size and shore stations of more importance, until he reaches the grade of medical inspector, when his service at sea consists usually of one cruise as surgeon of the fleet, and on shore in charge of the medical department of one of the large navy yards and important stations. As medical director his duties are confined to shore service, and he is required to fill one of the responsible positions of director of the large hospitals, member of some important board, or instructor in the Naval Medical

School. There is probably no field of occupation in which a medical man may cast his lot that will bring to him a more varied experience, professionally, socially, and educationally, or a wider range of usefulness than that offered by the naval medical service.

The foregoing brings out as much in detail as the space allowed to this paper will permit the advantages of a naval life, and it is perhaps essential, in the consideration of the subject of the naval medical service, that its disadvantages should also be dwelt upon. Formerly much was written and discussed regarding the difficulties placed in the way of a medical officer of the navy in performing his duties by the prejudices against staff officers held by those of the line in authority. These prejudices were, perhaps, the inheritance from old-time conditions and obtain very little, if at all, to-day. The medical officer of this era probably finds no more stumbling-blocks placed in his way than does the health officer of a large community or the medical attendants on large institutions having lay boards of control. The social position of the medical officer is as assured as that of any other officer in the service with whom he holds rank. Prior to 1898, the newly-commissioned officer of the medical corps found himself when ordered to sea in quarters that were neither commensurate with his age or the dignity of his profession. The word steerage, the name of the part of the ship to which he was assigned for quarters at this time, has probably influenced many young medical men from taking service in the navy. To-day this objection no longer obtains. The rank of the assistant surgeon insures him quarters in the wardroom in any ship to which he may be detailed, and his associates there are men of age and stability. All military service, however, demands subordination, and independence is a thing to be placed out of the calculations of a naval officer. Men of strong domestic tastes and inclinations should not take up the profession of a naval officer as their life work. The home is practically lost, and its enjoyment in the short intervals that come from time to time hardly compensates for the pain of its loss when it is taken away again. The choice of a naval career must largely depend upon the personal tastes of the individual. To most young men the mess life, the excitements of ship's duties, the constant change of scene and environment are attractive. The discomforts of living in a contracted space, in unwholesome parts of the world, in an undesirable habitation, mean little to him in his early days. As age creeps on and the discomforts of life are more easily felt, the disagreeable features of naval life are apt to more than balance the pleasures.

A naval officer, though assured of a comfortable income and provision for old age, cannot aspire to an accumulation of riches. The requirements of his official and social position exact, generally speaking, the expenditure of his salary, and savings are not the rule.

A comparison of the opportunities and returns of a professional career in the naval service with those of the same in civil life demonstrates, it is believed without question, that the naval medical service represents professional success and above the average enjoyed by one's contemporaries in civil life.

To one endeavoring to decide the choice of a professional field of labor, the advice is here offered to study well his personal tastes and inclinations. While success in the naval service, as in all walks of life, depends upon the individual, contentment and satisfaction with one's work in the navy more largely depend upon one' stastes and susceptibility to the influence of environment, for, perhaps, in no other career are tastes played upon to so great extremes, nor do surroundings undergo so frequent and marked changes.

THE PUBLIC HEALTH AND MARINE-HOSPITAL SERVICE.

By M. J. ROSENAU, M.D.,
DIRECTOR OF THE HYGIENIC LABORATORY, PUBLIC HEALTH AND MARINE-HOSPITAL SERVICE.

It is the ambition of thoughtful men to be occupied with the work they love, to have an opportunity of spending their leisure hours with the pastimes they prefer, and to have the privilege of enjoying the repose of peace and quiet in the evenings of their days. Those whose philosophy of life tends in these directions and who are satisfied with a modest competence, free from the worries and cares of commercialism, cannot do better than select a position in one of the medical departments of the Government service.

The question is sometimes asked us why we remain the servants of the Government when we might be independent in private practice. The answer is plain: The private practitioner is very many more times bound to the beck and call of his clientèle with less freedom and chance of relaxation than the "Government servant." The trite saying that "few die and none resign" has become an axiom in the Government service and well illustrates the contentment and calm which prevails in official circles. It means that many men of different temperaments from all sections of the country are satisfied with the emoluments and work of a medical officer of our Government. While such a position offers many advantages over the cares and strife of the active practitioner, it is not without its responsibilities and disadvantages.

Having been requested to give a short exposition of the opportunities for making a living in the Public Health and Marine-Hospital Service that are open to the recent graduate in medicine, I will briefly state the requirements and kind of examination for admission to the service, the nature of the routine work required of its officers, their pay and their opportunities for preferment; also, what offers in the way of travel, of pleasant companionship, and the winning of a name in science.

First, let me tell what the service is:

This service receives the first part of its long name from the fact that it has many public health duties to discharge, particularly the conduct of maritime quarantine, the management and suppression of epidemics, the medical inspection of immigrants, the maintenance of a hygienic laboratory in Washington, the investigation of sanitary problems, and many other matters affecting the national health. It was formerly called the "Marine-Hospital Service," from the fact that it has charge of the marine hospitals which are located at our principal ports for the treatment of sick and disabled seamen of the merchant marine.

The Public Health and Marine-Hospital Service is a bureau under the Treasury Department in charge at present of Surgeon-General Walter Wyman with a staff of assistant surgeons-general who are entrusted with the management of its various division details. Marine hospitals existed in the early days of our country under charters granted by King George III, but the service properly dates from July 16, 1798, when Congress passed an act for sick and disabled seamen, creating a fund for this purpose designated as the "Marine Hospital Fund." The benefits of these hospitals were extended to sailors in the United

States Navy until 1811, when Congress authorized separate naval hospitals.

In 1871 the service was reorganized and the position of supervising surgeon-general created, after which the Marine-Hospital Service rapidly outgrew its name; for, in addition to conducting marine hospitals, Congress from time to time imposed upon it additional duties and responsibilities, and its activities were so extended and its functions so multiplied that its work soon resembled that of a national board of health.

Therefore, in 1902, Congress gave the service its present name, the "Public Health and Marine-Hospital Service of the United States," at the same time further adding to its duties and responsibilities.

Advantages of the Service.—A service such as this, consisting of 108 commissioned medical officers, is like a large official family. The prolonged and intimate relationship between the officers of the service engenders the strongest ties of friendship, while the pleasant companionship and many social advantages which a life in the service offers add much to the pleasure of life. The discipline in the Public Health and Marine-Hospital Service is military in character, but while weekly inspections are had at each station, there are no tedious drills, and no time is wasted with routine exercises of a non-professional character.

Officers while on duty are required to wear the uniform prescribed by the President.

The particular advantage offered by this corps to graduates in medicine is that it is strictly a medical service. More than 50,000 sick and disabled seamen of the merchant marine are treated annually. Of this number over 12,000 are cared for in the twenty-two hospitals of the service. The service reports show that over 1,500 important surgical operations requiring the use of an anæsthetic are performed annually. Not only is great opportunity offered by this large clinic to study all branches of the art and science of medicine and surgery, but the class of cases treated offers an almost unparalleled opportunity for the study of rare and exotic diseases. Deep-water mariners bring strange and unusual parasites from all corners of the globe. Tropical diseases unknown in our climate may be found in all the seacoast hospitals of the service, affording abundant material for original scientific research. The hospital at Ellis Island, where thousands of immigrants arrive each year, is in charge of officers of the Public Health and Marine-Hospital Service. The service in this hospital is probably the most unique of any in the world. Here are collected strange diseases of strange people from strange lands.

In addition to the medical and surgical opportunities offered by the service, an officer has abundant occasion to exercise his administrative and executive abilities. Each station, whether hospital or quarantine station, is in command of a medical officer, which is a privilege few appreciate excepting those who have been hampered in their professional work by being subordinate to laymen.

Opportunities.—The various divisions of the service are in charge of older officers detailed as assistant surgeons-general, who have executive responsibilities of a high and difficult character, being responsible for the proper and economical conduct of the divisions entrusted to them. The service, as indicated by the first part of its name, performs public health work of a most varied and important character. It has waged many contests against yellow fever, and is constantly at warfare at the various quarantine stations along the gulf and South Atlantic coasts to prevent this dread scourge entering the country. This kind of work has given officers of the service the opportunity of winning enviable reputations as sanitarians.

The Public Health and Marine-Hospital Service also conducts a sanatorium for consumptives at Fort Stanton, in the high and dry climate of New Mexico. In compliance with the Interstate Quarantine Regulations it has taken an active part in preventing the spread of plague and cholera whenever these diseases have become a menace.

Opportunities are afforded to the corps to promote sanitary science either at the Hygienic Laboratory in Washington or by original investigation at the various quarantine stations and hospitals of the service, all of which are equipped with facilities for laboratory work of this character.

In order to prepare officers for the peculiar duties which confront them in the service, the younger officers of the corps are detailed to the Hygienic Laboratory at Washington in order to take a systematic post-graduate course in pathology, bacteriology, and various branches of the sanitary sciences that are not usually included in the medical curriculum.

From time to time officers of the service who show special aptitude for such work are detailed as special commissioners to study the cause and mode of transmission of diseases which menace the public health. In recent years there has been a leprosy commission, several yellow fever commissions (one at Havana and one at Vera Cruz), while officers of the service have been on numerous occasions detailed to study plague, cholera, malaria, smallpox, "spotted fever," and outbreaks of other strange and unusual diseases which appear from time to time.

Requirements and Entrance Examinations.—To enter the service a candidate must be an American citizen; if of foreign birth, he must furnish proof of citizenship. The age of the applicant must not be less than twenty-two nor more than thirty years. He must be a graduate in medicine of some reputable college, and must pass a satisfactory physical, academic, and professional examination before a board of three commissioned medical officers. The board of officers detailed for the purpose of examining applicants for appointment is convened from time to time as vacancies of the exigencies of the service require. The board usually meets in Washington in the spring of the year.

Examinations are both written and oral and are always preceded by a very thorough physical examination. This is followed by an oral quiz on academic subjects, particularly to ascertain the proficiency of the candidate in general literature, the languages, history, geography, and the natural sciences, such as chemistry, biology, and physics. The written examination of applicants for appointment begins with a short autobiography, in which the candidate states his age and place of birth, schools or college at which he received his general and medical education, the general branches studied, including his knowledge of general literature and the ancient and modern languages, the opportunities he has had of engaging in the practice of medicine, surgery, or obstetrics, or of receiving special instruction, and whether he has been a resident physician or interne in a civil or military hospital, and the number of cadavers or parts of cadavers he has dissected while at college or elsewhere. The remainder of the written examination consists of questions in each of the following medical subjects: (1) Anatomy, (2) physiology, (3) chemistry, (4) materia medica, (5) practice of medicine, (6) practice of

surgery, (7) obstetrics and diseases of women, (8) hygiene, (9) pathology and bacteriology, and (10) reports on special cases at the hospital.

Whenever it is possible applicants for appointment are required to perform operations on a cadaver, to show their skill in bandaging, and to demonstrate their proficiency in the technique of laboratory work. An average grade of 80 per cent. is required. An applicant for appointment failing at one examination may be allowed a second examination after one year, provided he has not passed the limit of age above mentioned; but he is not allowed a third examination.

Pay and Emoluments.—After entering the service the candidate is commissioned by the President, by and with the advice and consent of the Senate, as an assistant surgeon with compensation of $1,600 per annum. After five years of satisfactory service he is examined for promotion to the grade of passed assistant surgeon with compensation of $2,000 per annum. Passed assistant surgeons must wait for a vacancy in the list of surgeons, to which grade they are admitted only after examination. Surgeons receive $2,500 per year. Six of the older officers of the service are detailed to the Bureau at Washington with the rank of assistant surgeon-general and pay of $2,900 per annum. The surgeon-general receives $5,000 a year.

In addition to the pay above stated, officers of the service above the rank of assistant surgeon receive 10 per cent. increase of their annual salary after each five years of service. This increase is called a "fogy," or longevity pay, and officers are entitled to four such fogies after twenty years of continuous service. Commissioned officers of the service are also entitled to quarters, fuel, and lighting. Comfortably furnished quarters are provided at almost all of the hospital and quarantine stations; where no quarters are provided officers receive commutation at the following monthly rates: Surgeons, $50 at home and $90 abroad; passed assistant surgeons, $40 at home and $85 abroad; assistant surgeons, $30 at home and $80 abroad. Foreign commutation applies to any station situated beyond the geographical limits of the country as they existed January 1, 1898. This increased sum allowed for foreign commutation is in lieu of the increased compensation granted officers in the other arms of the Government service while serving in the Philippines and on other foreign details. Officers of the service and their families are also entitled to medical supplies. Thirty days leave of absence are allowed each year; leave of absence which is not taken accumulates until four months may be had with full pay.

Private practice is not regarded as inconsistent with the requirements of the regulations governing the service so long as such practice does not interfere with the proper performance of official duties. Officers stationed in remote places where skilled medical assistance is difficult to obtain are not infrequently consulted by citizens residing in the neighborhood. No fees are allowed for any professional, sanitary, or executive duties required by the regulations. Every inducement is offered to the officers of the service to publish the results of their investigations, whether of a clinical or a laboratory character, in the various bulletins and reports of the service or in medical journals, according to the circumstance of the case.

Seeing the World.—One of the most pleasant experiences which comes to a medical officer is when he receives his first detail to represent the Government at a medical meeting. The Public Health and Marine-Hospital Service is always represented at important medical and sanitary gatherings, whether at home or abroad. These duties offer exceptional opportunities for keeping in the van of medical thought and of presenting in written papers the results of original observations and research.

Those who like to travel obtain a full meed of such enjoyment during the whole course of their official life. All members of the service are subject to change of station. The regulations do not permit an officer to remain longer than four years at one place without being redetailed by the Secretary of the Treasury. The exigencies of the service constantly call for the services of experts familiar with epidemic diseases and sanitary problems, which involve much traveling back and forth. The hospitals and quarantine stations, as well as all contract and inspection stations, are regularly inspected in accordance with a definite plan. The service is also required by law to inspect, once each year, all establishments manufacturing viruses, serums, toxins, and analogous products. Boards of officers are convened in various parts of the country from time to time to examine candidates for promotion, to inspect sites for new camps or hospitals, to investigate the conduct of the service, and to perform miscellaneous duties and solve the many new problems that are constantly arising.

Actual traveling expenses and hotel bills, not to exceed $5 per day, are allowed medical officers while traveling under orders. This travel is frequently under the most pleasant circumstances and gives one an opportunity to see the world under advantages that can be scarcely appreciated by one not in the Government service.

The service now conducts both hospital and quarantine stations in Porto Rico, Hawaii, and the Philippine Islands, giving some of its officers the opportunity to take long sea voyages. At many foreign ports commissioned medical officers of the service are detailed for duty in the office of the United States consul in order to sign bills of health and supervise the sanitation of vessels leaving for our shores. At present there are three officers in Japan stationed at Yokohama, Kobe, and Nagasaki; two in China stationed at Shanghai and Hongkong; one in Naples, Italy; ten in Cuba; four in Mexico, of which two are stationed at Vera Cruz, one at Progreso, and one at Tampico; and six in the fruit ports of Central America, viz., Bocas del Toro, Columbia, Puerto Limon, Costa Rica, Bluefields, Nicaragua, Ceiba and Cortes, Honduras, Livingston, Guatemala, and Belize, British Honduras.

The medical officers of the Public Health and Marine-Hospital Service are given both time and opportunity for solving the great problems connected with the cause and prevention of disease. They enjoy exceptional opportunities to apply the sanitary sciences in the practical and useful work of keeping out exotic plagues, preventing the spread of epidemics, and scouring our fair land of its preventable scourges.

Pay of Medical Officers of the Russian Army.—Under the revised scale recently approved by the Tsar, medical officers of the Russian army on entrance to the service draw pay at the rate of 800 rubles ($400) a year. After five years this is increased by annual increments so that after nine years' service the officer draws $480 a year. After a further period of four years he gets $650 a year, and four years later—that is, after seventeen years' service—he reaches the amount of $750 a year. The highest pay which he can ever hope to get is $2,750.

THE INSURANCE EXAMINER.

By HENRY H. SCHROEDER, M.D.,
NEW YORK.
ASSISTANT MEDICAL DIRECTOR, MUTUAL LIFE INSURANCE COMPANY OF NEW YORK.

THE preparation of students for life insurance examining was not regarded as worthy of attention by our medical colleges until a few years ago when a short and, in some instances, elementary course was included in the curriculum of a few of those institutions. The subject should be looked upon as a branch of medicine, and it is strange that its importance has not been more fully recognized, since the duties of the examiner are quite different from those which one is trained to perform in the capacity of family medical adviser. The position is also a very responsible one, even though it does not bring actual sickness or impending death into immediate consideration, for the life insurance companies depend largely upon the faithful and intelligent services of their examiners in protecting the interests of millions of beneficiaries—the wives and children of the policy-holders. The time has come when it should be made clear to those seeking the position that there is something more worthy of their reflection than the mere question of increased incomes, and that it would be better to refuse appointments when through self-analysis they find that they are not up to the standard morally as well as mentally. The object of this brief article is to give a general idea of the advantages and disadvantages which the position carries with it, and also the duties and qualifications expected.

Number of examiners required.—The field for the medical examiner extends everywhere, from the country cross-roads to the largest cities, as every village is supposed to have at least one examiner and large places more in proportion to their size. Each of the large companies has over 27,000 examiners in the United States alone, and the smaller concerns are represented by almost as large a number, as their agents solicit everywhere, though the total amount of business secured by them is not so great. Examiners often work for several companies, and in small places this is unavoidable as there are not enough physicians available to give each company its own special representative. This practice is not confined to villages or small towns, as physicians are frequently met in larger places serving half a dozen different companies. It is, therefore, impossible to give even an approximate number of medical examiners in the United States, but it cannot be other than very large. There are companies that transact business in foreign countries where they usually select native physicians on account of their knowledge of the language and the people. It occasionally becomes necessary, however, to send some one abroad after he has received a special training at the home office; this is found advisable more especially in those countries where the principles of life insurance are not well understood either by the medical fraternity or by the public at large.

Applications.—If the company has a medical referee for the district in which the applicant lives, a request for appointment should be made to this official, whose duty it is to keep himself informed as to the standing and acquirements of physicians in his territory, or, at least, to have some means for accurately ascertaining those particulars. If there is no referee, and the local manager of any company will gladly enlighten an applicant as to whether there is or not, correspondence should be directed to the home office.

The great majority of applications received by the companies are mere requests for appointments, and are not accompanied by endorsements of reliable and well-known persons or by satisfactory credentials. Such communications are filed, but, as they are of no value, they are usually ignored when occasions arise for the selection of examiners in those sections, and the choice falls upon others, perhaps, who have been found competent through information obtained by methods which the companies have at their command.

It is a general rule to refuse applications for appointments unless vacancies have occurred through suspension on account of incapacity or inefficiency, removal of examiners to other fields, or death. Any other policy would cheapen the position and give the present incumbents some degree of uneasiness as to the future demand for their services. There are times, however, when it becomes absolutely necessary to enlarge the existing staff on account of an increase of business or the discovery of some locality in which there is no examiner.

Medical men have sometimes been tempted to take out insurance, the agents promising to secure their appointment as examiner as a reward, and leading them to believe that they will earn more than enough in the way of fees to pay the premiums. It must be admitted that a few companies stamp this questionable procedure with their approval by making needless appointments in such instances, and that they are equally ready to repeat the performance as often as the agent can induce the neighboring physicians to play into their hands. *Verbum sat sapienti.*

Fees and Salaries.—Nearly $5,000,000 is distributed annually among the life-insurance examiners of this country. The individual's share of this vast sum varies, of course, according to the locality and size of the place that he has selected as a field for his practice. In villages it may not exceed $100, or even $50, a year. If, however, an energetic agent arrives in the neighborhood he may write insurance enough in a short time to bring in more than this to the local examiner as compensation for his services. In towns and small cities the examiner may expect to realize from several hundred to one thousand dollars. Here, again, the efforts of the agents must be taken into account, for it is only in the large cities that we are sure to find active and able solicitors at all times. In the large cities the earnings of examiners vary widely according to the company they represent, their rank, and the size and importance of the district to which they are assigned, and range from about $600 to about $2,500 a year. There are those who receive more by giving their time exclusively to this work, but it is questionable whether this is advisable or not, as they must depend upon several companies, none of which assure them permanent positions.

The largest companies have adopted the custom of paying their examiners by salary in most of the great cities, especially in New York City. In New York an examiner is started, as a rule, with a salary of $1,200, for which he is expected to devote at least two hours in the Home Office and to make several outside examinations, so that the amount of time given up by him is from four to six hours a day. During dull periods he is able to finish his work in less time, but he is always supposed to complete the work of the day, even in the occasional busy seasons when it may take much longer. Examiners are always needed in the outlying districts of these large cities and, when on salary, receive about $600 a year. For this they make all the examinations within certain limits, but are not ex-

pected to go outside of their territory or to appear at the Home Office. The examiners at the Home Office, working directly under the supervision of the Medical Board, do not have as great a responsibility as those stationed in distant large cities where applications are also made daily for large amounts of insurance. It therefore becomes imperative to select men with long and wide experience at these points with remunerations in keeping with the high order of skill and care expected, the salaries in a few instances running as high as $3,000.

The fee system is retained by the small companies, as even in large cities the number of applications received by them for insurance does not warrant the payment of salaries; so there is an understanding by which the examiners receive the usual fee of $5 for each case and, in a few instances, report at the Home Office daily for a short time. As the corps of examiners consist of only a few men, an examinership in one of these companies is found to be satisfactorily remunerative.

It is possible to treat this subject of fees and salaries only in a general way, and these remarks must not be considered as referring to any one company. Each concern has its own rules and customs, which often differ radically from those of its competitors.

Advantages.—Some will probably conclude that the remuneration is not large enough to make it worth while, especially in small places. We can only say that during the intervals between examinations, one will have the consoling thought that he is really losing nothing, as no capital or expense has been demanded from him other than is actually indispensable to a general practitioner. Then again, the sum of $100 in a village where the cost of living is comparatively slight, is equivalent to several times that amount in towns or cities. There is also some benefit to be derived from the prestige and reputation that come to a physician in whom a great corporation has shown its confidence and faith; this is especially true in small communities where everyone is more or less conversant with his neighbor's affairs. Still another advantage is the examination of a healthy body occasionally; we all are aware of the importance of this practice for the purpose of keeping the faculties keen and well-balanced, but very few follow it up unless it comes in line with their regular work. The examiner also receives some mental training, too often needed, through requests from the Home Office to complete or revise unsatisfactory physical examinations and unfinished reports.

Whatever the income amounts to, it is sure to be paid promptly each month whether he recommends or rejects the risks, and there are none of the irritating delays in collecting that are unfortunately experienced in private practice. Salaries are paid semi-monthly as a rule.

It has been our experience to find that a doctor is seldom too busy to accept an examinership, for he can make many examinations without consuming the whole or even a large part of his time. His private practice, which is naturally of most importance to him, will not be interfered with; it merely requires some method in the arrangement of his hours to do both kinds of work to the satisfaction of all concerned. It frequently happens that through making a more careful and painstaking examination than the applicant has been accustomed to, a closer intimacy is begun and a new patient added to the list.

Disadvantages.—There are no disadvantages to a conscientious and efficient examiner worthy of consideration, for the worst that can happen to him is the incurrence of the displeasure of the applicant or the agent when it becomes his unpleasant duty to advise rejection of the risk. No one is more vulnerable to the attacks of an enemy than the physician, especially in small communities, so it becomes a matter of self-preservation with him to avoid all controversies and unkind criticisms as far as he is able. A disgruntled agent or, worse, an angry applicant who thinks he has been treated unjustly can undeniably do considerable to injure the reputation of an honorable and well-meaning doctor. The liability of this undesirable complication must be borne in mind when an application for an examinership is contemplated, for it has been of too frequent occurrence, and led to bitter animosities lasting for years and even for life. Tactful management and good judgment will do much to prevent such strained relations. Then, again, the companies realizing the possibility of such a poor reward for services rendered in their favor, provide forms for confidential letters in which the examiner may freely give an expression of his opinion, though his regular medical report contains no unfavorable comment; these letters are sent directly to the Home Office and are looked upon as confidential. With this resource at his command we feel free to state that when an unpleasantness arises, it begins with poor management on the part of the examiner.

Requirements.—Men who possess skill, education, and training are naturally selected whenever possible. The physician who has graduated from a first rate school of medicine, has seen several years of practice, has been an interne in some regular hospital, and is in good standing, will receive the preference. The country practitioner is not always able to meet all these requirements, and the selection must be made from the best obtainable. We wish to say, however, that with the few exceptions that occur to every rule, the insurance companies have no more conscientious, painstaking, or faithful workers than the country examiners. In the larger places there is no difficulty in obtaining men who have all the qualifications desired.

During the past few years the large companies have adopted the admirable custom of training a necessarily limited number of men who have had a hospital experience. They remain at the Home Office for a period of from one to three months working under the supervision of the regular medical staff, and receive while there about $100 a month as compensation for their services. When the period of probation has ended they are given important posts at distant points. Only those are chosen for these positions who can furnish the very best credentials.

Generally speaking, those who possess the ability and temperament necessary to the making of a good family practitioner, will prove satisfactory as examiners. There are certain qualities that are so invariably found in the *ideal* examiner, however, that it will be well to specify them with the hope that they will be studied by the prospective applicant. In addition to a good professional education and standing, he must be a man of strict integrity and sobriety. The possession of a common-sense shrewdness in judging men's characters and lives and the ability to estimate the value of past and present conditions from a practical standpoint, places him on a higher plane of usefulness than one who is a pure theorist. He is expected to be obliging in disposition and willing to make further investigation or examination on request from the Home Office, even though the fee does not compensate him for the extra services given in this individual case; in such instances he ought to find

consolation in knowing that he usually receives very liberal payment for his work. He must feel that he has sound discretion and firmness in maintaining his position without giving offence or irritation. Courtesy and power to maintain a calm state of mind on all occasions are most desirable qualities in an examiner, for there will be times, happily not often, when he will be subjected to annoyances and criticisms without just cause that will make it seem beyond his endurance to hold himself in; if, however, he loses control of his temper on such occasions, no matter how great the provocation, he also loses ground and sympathy; but if he maintains a courteous bearing and unruffled dignity, he has the best of the situation and keeps himself above the level of his opponents. While on this subject, we would once more call attention to the value of that great asset, tact; for we know of no position in which this quality conduces more to a good mutual understanding and peace of mind to all concerned than in the one under discussion. Examiners, most efficient in every other way, have brought down the wrath of the parties immediately interested and incurred the displeasure of their superior officers, all of which could have been easily avoided by the exercise of just a little bit of tact. The examiner should always bear in mind that he is serving others, the company and the agent, whose interests are much greater than his own, and for this reason should keep his own feelings in the background and ignore slights and injustice. It should be his endeavor always, on parting from the applicant and the agent, to leave them good friends to himself and the company, even when it has been his unpleasant duty to give an opinion adverse to their interests.

Each applicant should feel confident that he will be able to fulfil these duties and requirements, as well as be ambitious to become an ideal examiner. His greatest reward will be his own consciousness of work well done, and the appreciation of those who are competent to estimate the worth of his achievement, compared with which fees and salaries sink into insignificance.

SALARIED POSITIONS OPEN TO MEDICAL MEN IN THE LARGER CITIES.

By HENRY A. HIGLEY, M.D.,
BROOKLYN, N. Y.

It is only during the past twenty-five years that the medical man as a salary drawer has come into prominence in the large cities of this country. Previous to that time the salaried positions held by the physician were few and in the greater part limited to official governmental or municipal situations which consumed the holder's entire time and which he entered with the intention of devoting his life's work thereto. Within the period above mentioned the official municipal positions open to medical men have been markedly increased in number and coincidently similar opportunities have been opened in connection with various commercial enterprises and so-called "benevolent" organizations. It is well known that in such positions in the vast majority of instances the physician receives much less compensation than he would obtain for a like expenditure of time in what may properly be called the "legitimate" practice of medicine, and that the remuneration received is in no way a fair valuation for the professional services rendered. Nevertheless observation will show that to-day in our large cities many physicians are either holders of such positions or seekers after the same. It is a curious fact that simultaneously with the development of this condition of things the requirements for admission to and graduation from our various medical institutions have been enormously increased, so that to-day far more is demanded of him who would enter the medical profession with respect both to financial outlay and time expended than has ever been previously required; thus with a maximum of preparation we find the medical man to-day, in many instances, offering his services for a minimum of compensation. There are doubtless many reasons why this is so, but in the last analysis the fundamental cause is to be found in the universal law of supply and demand. In other words, the supply of medical men offering their services in the time-honored practice of medicine exceeds the demand for the same, and we find those who are unable in a short time to gain a foot-hold along such lines willing and ready to market their knowledge at lower rates. The most important accessory cause is to be found in the development of the principal of consolidation which during the last quarter of a century has reached enormous proportions in the large business centers of this country so that individuals have bound themselves together in many lines in order to obtain various commodities at reduced rates. In the wide extension of this principle the endeavor to obtain medical services at "cut rate" figures has not been lost to view. Although, from the standpoint of the medical man, the situation thus forced upon him is to be regarded as a retrogression rather than an advancement, it is nevertheless certain that it arises from conditions which cannot be controlled in a large and rapidly developing community, and must be faced and dealt with wisely and courageously, so that debasement of the profession may be avoided and the high ideals which should inspire every true physician maintained. In order that this may be the case any man who possesses the ultimate desire to become a practitioner of medicine, but who on account of financial considerations is obliged to accept a salaried position, must constantly hold in mind the precept that such a position is only a stepping-stone to be temporarily utilized and as soon as possible thrown aside and not allowed in any way to interfere with the main object in view. This is far from being an easy task, but in the past it has been successfully accomplished by many medical men, and it is not too much to say that it is capable of accomplishment by almost any one who is worthy the name of physician. To this end he who is obliged to enter the salaried ranks ought to endeavor to obtain that position which is best suited to his individuality, and the duties of which, conforming to his intended line of work, he can satisfactorily perform with the least amount of abstraction from the ultimate aims in view. This is a personal question with every man and should be given careful thought and consideration. A review of the various salaried positions open to medical men in our larger municipalities is, therefore, not out of order, since thus a survey of the field may be obtained and the probabilities of an advantageous choice increased.

Health Department.—In any municipality the larger number of salaried positions open to medical men are the official ones, and of these those offered in the health departments, on account of their number and importance, lay the first claim to our attention. The municipal health departments in our larger cities are organized substantially upon the same lines. There is, of course, a slight difference in the designation of the various positions, but for all practical purposes a detailed consideration of one of them is sufficient for a satisfactory understanding of the others. For our consideration, therefore, we will chose the Health Department of New York City,

since it is the largest and in many respects the most completely organized in the country. In this department there are constantly employed upon salary upward of 240 physicians. In addition numerous temporary appointments are made as occasion and emergency require. The positions offering constant employment to physicians with the yearly salaries attached are as follows: A general medical officer, $5,000; a sanitary superintendent, $5,000; five assistant sanitary superintendents, $3,500; two chief inspectors of contagious diseases, $3,000 and $2,500; one assistant chief inspector of contagious diseases, $2,550; fourteen diagnosticians, $1,200 to $1,800; 170 medical inspectors, $1,200 to $1,800; fifty-two sanitary inspectors (one-half of these may be physicians), $750 to $1,800; one superintendent of hospitals, $2,500; three hospital physicians, $1,800; three assistant hospital physicians, $1,200; one registrar of records, $4,000; four assistant registrars of records, $3,000; one assistant director of the bacteriological laboratories, $2,110; one assistant director of the vaccine laboratory, $1,800; one assistant director of the diagnosis laboratory, $1,800; twelve assistant bacteriologists, $1,200. As stated, temporary appointments may be made in any of the divisions, physicians thus appointed drawing salary for the term of employment at the same ratio that the permanent employees in similar positions receive. All of the positions, except the general medical officer, the sanitary superintendent, the assistant sanitary superintendents, and the registrar of records come within the civil-service law, and competitive examinations for the same are held by the Municipal Service Commission as occasion may require.

Since the majority of the official positions open to medical men in other municipal departments come within the same regulations, it may not be out of place to review the salient features of the same in this place. In order to pass these examinations and be placed upon the lists from which appointments are made the applicant must make at least 75 per cent. on the technical paper. Such lists are made up in the order of percentages obtained—the applicant with the highest percentage heading the list and so on. When appointments are to be made three names for each appointment are taken from the top of the list and submitted by the civil service commission to the appointing power. Any one of the persons so certified may receive the appointment. In the case of those not appointed their names are placed back on the lists from which they were taken in the same relative positions which they originally held—that is at the top of the list. When any one name has been thus certified to the appointing power three times without appointment being given, such name is permanently dropped from the list. In the cases of temporary appointments the names of the holders, when their services are dispensed with, are placed back on the lists from which they were taken in their original relative positions. Civil-service appointees cannot be discharged except for dereliction in duty, abolishment of the position which they hold, or necessary curtailment of the service. The appointments to the positions above noted which do not come within the civil-service law are made at pleasure by the appointing power, and the holders of the same may likewise be dismissed at will except in the case of veterans, when either the position must be abolished or due cause for dismissal must be assigned. The first essential qualification for appointment to any of the medical positions is that the applicant shall be duly qualified to practise medicine in the State and city of New York. An essential qualification for appointment to the non-civil service positions above noted, the chief and assistant chief inspector of contagious diseases and the diagnosticians, is that the applicants shall have had sufficient *practical* experience in their respective fields to enable them to perform the duties of the office to which they aspire. The examinations for medical inspector and medical sanitary inspector include general medical knowledge with especial reference to contagious diseases, diseases of the eye, and skin diseases, and also a fundamental knowledge of sanitary science. That for assistant bacteriologist presupposes a knowledge of bacteriological technique supplemented by laboratory experience. For superintendent of hospitals, hospital physician, and assistant hospital physician the examination comprises general medical knowledge with especial reference to the diagnosis and treatment of contagious diseases and also hospital sanitary regulations. For assistant registrar of records the applicant must be proficient in the compiling of mortuary statistics and must show a fundamental knowledge in the principles of the same.

The duties of the various positions are as follows: The general medical officer has a general supervision of all branches of work which come within the sanitary and contagious-disease divisions, and is the chief advisor of the board with respect to the policy of the department relative thereto. He is not concerned with the technical performance of the work. This comes within the domain of the sanitary superintendent who supervises the routine work of the sanitary and contagious disease divisions, and is responsible for the satisfactory execution of the same. The duties of the assistant sanitary superintendents are the same as those of the sanitary superintendent, except that they are limited to the districts over which they preside. The chief inspector of contagious diseases and his assistant superintend the routine work of the contagious-disease division and are responsible for the work of the medical inspector in all its details. The duties of the medical inspector, which comprises the largest class of physicians in the employ of the department, are varied and may be considered under three subdivisions, to any one of which the medical inspector may be assigned at the discretion of the chief inspector of contagious diseases:

1. *Routine Medical Inspection Work.*—Here the inspector is given a district. He receives daily notification from the chief inspector concerning the location of the cases of contagious diseases reported in the same. He visits these patients within twenty-four hours of receiving such notification, and puts into execution the rules and regulations of the department relative thereto. He is responsible for the satisfactory carrying out of the same, and must revisit the patient at sufficiently frequent intervals in order to see that this is being done. If the use of antitoxin is requested by the attending physician, he administers the same. At the conclusion of the case he arranges for the disinfection of the premises and the return to school of the children who have been excluded therefrom.

2. *Medical School Inspection.*—Inspectors who are assigned to this division of the service are given a certain number of schools, which they visit daily, examining the pupils for evidences of contagious diseases, including various affections of the eyes and skin. They immediately exclude from school attendance all pupils who give evidences of the same.

3. *Vaccination.*—The inspector is given a district, which he canvasses daily with a view to obtaining vaccinations. Of these he is supposed to return at least 100 per week. In cases of epidemics of smallpox he does special vaccination work in the parts of the city affected or wherever his services may be required.

In addition to the above, medical inspectors may

be assigned by the chief inspector at any time to do special work which the needs of the contagious-disease division require. Also one of the medical inspectors is assigned at the pleasure of the chief inspector to night duty at the office of the department. During the summer months a corps of physicians is appointed from the medical inspector's list, who do duty under the name of the "summer corps." They are given districts in the tenement-house sections of the city, which they visit daily with the object of treating the sick children of the poor. They are supposed to devote eight hours per day to this work. The medical sanitary inspectors attend to the investigation of citizens' complaints regarding the violation of sanitary ordinances. Each one is allotted a district similarly as medical inspectors.

Diagnosticians make the official diagnoses for the department. They have their districts and are sent to every case reported therein in which removal to the contagious disease hospital is requested or necessary. They also discharge the patients from the department hospitals at the expiration of their sickness. The superintendent of hospitals has charge of the business end of the department hospitals and is the immediate superior of the hospital physician and his assistant, whose duties are similar to those of the ordinary resident physicians in any general hospital. The registrar of records and his assistants have entire charge of the vital statistics of the department and the reception and granting of death certificates, burial permits, etc. The three assistant directors of the bacteriological laboratories superintend the work of the research, vaccine, and diagnosis laboratories respectively, and the assistant bacteriologists are assigned to work in either of these three divisions. The work in the research laboratory comprises the manufacture of the various antitoxins prepared by the department and also research along such lines as may be suggested by the assistant director in charge. The work in the vaccine laboratory is limited to the production of vaccine. The diagnosis laboratory deals with the examination of diphtheria cultures, Widal tests, examinations for the malarial organism, and such other bacteriological diagnostic work as may be required by the assistant director in charge. With respect to the time required for the satisfactory performance of the duties of any of these positions, it may be said that the sanitary superintendent, the chief and assistant chief inspector of contagious diseases, the registrar and his assistants, the superintendent of hospitals, together with the hospital physician and his assistant, the assistant directors of the bacteriological laboratories and the assistant bacteriologists, with the exception of those employed in the diagnosis laboratory, are forced to give their entire time to the service of the department, at least to the extent of eight hours per day. The time required in the other positions is extremely variable, and depends largely upon the time of year and many contingent circumstances. In general it may be said that it varies from three to eight hours per day. The work of diagnostician, medical inspector, and medical sanitary inspector does not prevent the holders of such positions from practising medicine, nor does it materially interfere with a limited carrying out of the same. The positions most suitable for new appointees in the service of the department are those of medical inspector, medical sanitary inspector, assistant bacteriologist, and hospital or assistant hospital physician. Indeed, for all practical purposes, previous experience in the work of the department is a necessary requisite for appointment to any of the other positions.

The question is often asked by young physicians —Does Health Department work pay? It is impossible to answer this question without an accurate understanding of all the conditions which surround each individual case. In general it is certain that it does not, for in most cases he who enlists in the service gradually becomes more or less dependent upon the same and fails to progress in the ordinary lines of the profession. Such is by no means, however, necessarily the case, and there can be no question but that for the young physician many of the positions offer a permanent salary, which is an important aid in the first years of practice. Those who are wise, however, relinquish the position as soon as financial conditions permit.

Police and Fire Departments.—The official municipal positions open to physicians in the Police and Fire Departments are very much more limited in number than those offered in the Health Department. They are, however, more desirable in every way. The holders of these positions are known as police and fire surgeons respectively. In the Police Department of New York City the total number of such surgeons may not exceed forty, while in the Fire Department only six are allowed —three to the Boroughs of Manhattan and the Bronx and a like number to Brooklyn and Queens. The police surgeons receive $3,000 per year and the fire surgeons $2,000. In both instances the appointment continues for life and the holder cannot be discharged except for dereliction of duty. As might be expected, the competition for these positions is exceedingly keen and appointment is largely a matter of political influence. All of the positions come within the civil-service regulations, the fundamental requirements of which are the same as those for appointment to positions in the Health Department. The technical examinations, however, are very much more severe, demanding an advanced knowledge of both general medicine and surgery. The number of physicians who take these examinations from time to time is very large and the lists as a consequence are bulky. As is the case with all civil-service lists each list remains in force for but two years, a new examination being held at the end of this period. The duties of these positions are essentially the same, the physicians holding the appointments giving medical attendance to the uniformed members of the Police and Fire Departments whenever such is required. To this end each surgeon is allotted a certain portion of the force and is supposed to be upon constant call for attendance to the members therein. The amount of time required for the satisfactory performance of this duty is, as might be supposed, extremely variable, but it may be safely said that it does not average over two or three hours per day. These positions open the way to a considerable amount of additional practice, for such surgeons in their official capacity are not required to give attendance to the families of the members of the uniformed force, their work being exclusively limited to attendance on the members themselves. As a matter of fact, however, they are constantly called upon to treat such families for which they are allowed to charge and receive whatsoever reasonable fee they see fit. The practice thus obtained forms no inconsiderable addition to the income of the police and fire surgeons. While these positions are very desirable, it must be understood that they are practically not obtainable by recent graduates in medicine, as the vacancies created are extremely few and the requirements such that successful applicants are almost universally men who have had considerable experience in the practice of medicine.

In the **Street Cleaning Department** there are three salaried positions open to medical men. The hold-

ers of these positions are called medical examiners and they receive a salary of $1,200 per year. These are civil-service positions and the examinations therefor comprise general medical knowledge. The duties of the office consist in the examination of the uniformed force of the department with respect to their ability to perform various duties. They also visit such employees who are on sick leave and certify to the character and probable duration of the illness. The time required of the physician in this capacity does not exceed two to three hours per day.

In the **Department of Public Charities,** as also in the **Department of Correction,** there are numerous salaried positions for physicians. In the majority of instances they are hospital positions and require the holder's entire time. They come within the civil-service law and pay a salary of from $500 to $1,500 per year. In addition to these there are the positions of visiting physician to the city jails and penitentiaries. These offer a salary of from $1,000 to $2,000 yearly and require but a small daily portion of the holder's time.

The Tenement House Commission offers two or three positions to physicians. They come within the civil-service law and command a salary of $1,200 per year. The examination is principally composed of questions relative to sanitary science, and the duties of the office consist essentially in a supervision of the execution of the sanitary code relating to tenement houses. From four to eight hours per day is required in this class of positions.

Quarantine and Immigration Services.—In al cities which are seaports there are certain official positions open to medical men in connection with the quarantine and immigration services. In the quarantine service the positions do not come within the civil-service law, but are the personal appointments of the Health Officer of the Port. The holders of such positions are called "deputies," and their duties are varied. At least one does duty as hospital physician at the quarantine hospital. The others are called "boarding deputies." These board the incoming vessels and examine the passengers for evidence of contagious disease, taking counsel with the ship's physician relative thereto. All physicians employed in the quarantine service devote their entire time to the work, and are not allowed to engage in the practice of medicine. The salaries attached to these positions vary with the size and importance of the port. The deputies of the port of New York receive $3,000 per year. The position of health officer of the port is essentially a political one, the appointment being made by the Governor of the State.

In the Immigration Bureau the deputies belong to what is known as the marine or coastwise service. Here a competitive examination, which comes within the governmental civil-service regulations, is held for appointment to the position. Appointment is made by the surgeon-general of the Public Health and Marine Hospital Service. The deputies are stationed at the various immigration stations and attend to the medical examination of all immigrants arriving at the port. They are required to devote all of their time to the service and receive from $1,200 to $2,500 per year. At the present time all cases of contagious disease which have broken out among emigrants, while under detention at the immigration stations, are transferred to the care of the municipal health department of the city and removed to the contagious disease hospital of the same. A movement has recently been inaugurated by the Government to establish contagious disease hospitals at the different immigration stations, so that in the near future additional salaried positions in connection with this service will doubtless be open to medical men.

Corporations and Business Houses.—As previously stated, in addition to the official municipal positions, various opportunities are open, in large cities, to medical men for salaried employment in connection with numerous corporations and business enterprises. Among the most important of such opportunities are to be mentioned those offered by the various *street railway corporations*. By these, physicians are employed chiefly for two distinct purposes, viz., (1) To examine and give medical service to such persons as are injured in any way by the vehicles of the corporation; (2) To examine such persons as the company may desire, with a view to ascertaining the extent of the injury, so that the corporation may have, at the time of the suit for damages, expert medical testimony with which to protect itself. Those who obtain the first class of positions usually do so by means of personal influence, which they exert with members of the corporations in which they seek employment. The salaries which they receive vary from $1,200 to $2,000 per year. The time required does not exceed three or four hours per day. Those who belong to the second class and who are chiefly employed to give expert testimony upon trial are usually surgeons of more or less repute in the municipalities in which they reside. They receive a much better compensation than the first-class, usually from $1,500 to $3,000 yearly. They are employed by the corporations only in the more important cases, and are not required to devote more than a small fraction of their time to the duties of the position.

In recent years all of the larger *manufacturing concerns* have been accustomed to employ upon salary one or more physicians to give medical attendance to such of their employees as may from time to time be injured during the performance of their duties. Such positions are obtained through personal influence and the holders draw a salary of from $500 to $1,200 per year. The latter figure is scarcely if ever exceeded. Although in these positions the salary is small, it is also true that in the average the time required of the physicians so employed is inconsiderable. Outside of certain official municipal positions these places are the most to be desired, especially by young physicians, of any salaried positions which are open to medical men in large cities, since they afford excellent opportunities to extend one's practice, particularly if the holder is located in that region of the city where such employees mostly reside.

Very recently there has been a movement started by several of the large *department stores*, which are now numerous in all big cities, to employ physicians for attendance at the shops in order to give medical aid to such of their patrons as may be taken ill while making their purchases. The salary offered in such positions is small, scarcely ever over $1,200 per year, and the time required is great, almost always eight hours per day, so that these positions are among the least desirable, since they materially interfere with endeavors to establish one's self in the practice of medicine.

The Race-track.—During the racing season physicians are employed by the different jockey clubs to be present during the races and attend such jockeys or other employees as may be injured. These positions are obtained through personal influence and pay $100 per month. They are, of

ourse, available only during a limited portion of he year.

Not least to be mentioned are those salaried ositions for medical men which are offered by *edical publishing houses*. These positions are nostly of a literary character, and as such require pecial ability along the lines in which such workers re employed. By these houses various sorts of iterary work are demanded, and the positions range ll the way from that of a simple translator of nedical articles and books, or reader of manuscripts, to the editorship of a medical periodical. Work of this kind is paid for by the "piece," or by stated salary. The salaries given show wide imits—from $300 or less to several thousand dollars er year. Most of these positions possess the double dvantage that they require no specified time for ervice, and that the necessary duties involved ompel a man to keep thoroughly in touch with the nost recent advances in medicine and the allied ciences.

Lodge Practice.—Finally there come for consideration those salaried positions which are open to medical men in the employ of the so-called "benevolent" organizations. Physicians thus employed are known under the general appellation of "lodge doctors." In the last fifteen or twenty years these organizations have enormously increased in this country, so that, at the present time, they include, in addition to many so-called "fraternal" orders, associations of employees of almost all manufacturing concerns or corporations in which upward of 200 or 300 individuals are employed. As is well known, these persons form an association, the yearly dues of which are $1 or $2. The sum thus collected, which, of course, varies according to the number of enlisted members, is paid to some physician who contracts to give medical attendance therefor to all of the members throughout the year whenever such is required. He is also usually supposed to treat the family of the members at one-half his usual rates. The disadvantage and injustice of this system to the medical man have been amply discussed in many publications, and are evident to any one who gives the subject any careful consideration. Nevertheless, it is a fact that not only do such associations have no difficulty in obtaining physicians to fill these positions, but that they are more or less constantly besieged by applicants therefor. It seems certain that this condition of things is not temporary but that it has come to abide. It cannot be ignored by the profession at large, and must be carefully dealt with, although in what manner does not as yet seem entirely clear. There can be no question but that the vast majority of physicians who seek employment in such organizations are in sore need of the compensation received therefrom. They are not to be unduly or harshly criticised by their brother practitioners. These ought not to be considered as dishonorable positions, but they are certainly the last to be considered by the physician who seeks salaried employment, with the exception of those which are offered by the advertising patent medicine concerns.

The "Green Plague" in Manchuria.—The St. Petersburg correspondent of *The Sun* reports what is believed to be a new disease, called the "green plague," has broken out among the Russians quartered in Chinese houses in Mukden. "The eyesight is first affected, after which green spots appear on the body. The disease is highly contagious. A majority of the cases are fatal. The Chinese seem to be immune."

THE RAILWAY SURGEON.

By WILLIAM W. SANFORD, M.D.,
NEW YORK.

FEW physicians have passed through the very early period of their life-work who have not experienced a longing for something to do, that would fill up the hours of leisure, increase their experience, and perhaps add to their slender income. This is probably more true of those living in the larger cities than of those in small towns. Not all will desire to devote time to the professional service of railways, but for those who do so desire a word may be useful.

The method of introduction to the governmental bodies of railroads is a matter for the individual to learn for himself. It may be by chance of a friend, or of one's presence in time of need, whereby one's existence is made known, and the acquaintance thus formed should be carefully continued. Young physicians, like other ambitious young men, must learn how to make and hold friends; they must be alert to seize every opportunity to make the personal acquaintance of railroad managers, and yet without the slightest appearance of intrusion. In many instances the formal application by letter to the chief surgeon, president, or general manager of a road will be formally and often favorably considered, the necessary qualifications outlined, and appointments made. In the possibly more fortunate occasions, an aspirant may hold the key of influence which, in railroad as in other cases, opens the door of position with no difficulty.

The organization of the medical service of a railroad varies somewhat on the different roads. Generally speaking, the medical department of the railway is presided over by the surgeon-in-chief. The responsibilities of such positions are often far-reaching. The duties are made more effective, however, when the surgeon-in-chief possesses the power to appoint assistants, whose duty it may be to assume the responsibility of their divisions, the work in which, however, is carried on by their assistants, better known as the company surgeons. When such a system is in vogue, it is the custom for the local surgeon to make his report of work done to the assistant chief of his division, and the assistant chief in turn to report to the surgeon-in-chief of the railway. This is not, however, the general rule with all railroads, for it is often customary for the local surgeon to report to the surgeon-in-chief directly.

On some railroads the office of a chief surgeon is entirely wanting, as is the case on one of the leading trunk lines of this State. There is no surgeon-in-chief, but between the terminal points are a few surgeons who are paid a nominal salary, these being, as far as possible, men of large experience. The company surgeons along the general divisions attend to the accident cases, and make a monthly report to the division claim agent.

The formal medical examination of applicants for employment, as to the nature of the organs of sight and hearing and the physical condition, is usually carried on by an especially appointed physician, or a specialist in diseases of the eye and ear. This examination may, of course, differ widely as to form, and the salary differs in different cases.

Should an accident occur which demands surgical attendance, the local surgeon living nearest to the place where the accident has taken place is notified, and if he can devote his time to the case at at once, he does so; if not, he may secure the services of a fellow surgeon. Having completed the work, he may at once forward to the surgeon-in-chief a report, outlining the nature of injury and

treatment, or may do so at the termination of his service upon the case.

Some railroads have a special agreement with hospitals in the large cities along their line, where special and needy cases are treated by a surgeon who is paid for his services in each individual case. On some roads there are special hospitals erected at convenient points for the care and treatment of the wounded.

Except in case of accident, the railway surgeon is not expected to attend the employees of the company when ill, those being supposed to employ and pay for the services of their own physician. The man who is known to be the company's surgeon, however, stands a good chance of being consulted privately by the emp oyees. This slight help toward an increased clientele, and the experience in acute surgery, are the chief advantages of the position of railway surgeon, for the emoluments of the office are small. The local surgeon is usually given an annual pass over the road for himself and his immediate family, and he also receives a not too liberal fee for work done after rendering immediate aid to the wounded, this fee varying according to the nature of the injury and the length of attendance.

The chief surgeon receives a salary, which in some instances is liberal enough, and in others rather meagre. The division surgeons may also receive a stated sum, or they may be paid according to the work done.

It is rarely the case that the local surgeon has much time to devote to original investigation, but it remains a fact that there is much to be done and much to be learned. It is strange that, in view of the advancements made in other departments of our great systems of travel, little or nothing has been done to insure better and more prompt attention to the multitudes who are injured daily upon these great accident centers.

The phenomenal increase in passenger and freight transportation upon our railroads in recent years and the constant desire for greater speed, must increase the liability of danger, not only to passengers, but also to the employees of the roads.

There probably never existed a more united opinion among the profession than at the present time, in favor of better equipment of the medical and surgical departments of our great systems of transportation.

The governing powers of those corporations are beginning to demonstrate by their actions, that they have a desire to improve the present conditions. This was clearly shown recently by President Underwood of the Erie Railroad when he directed that a special hospital car be supplied with the necessary equipment for all emergencies in case of accidents. Some of the principal Western roads have followed this example. It is in such cases that the railway surgeons may demonstrate their usefulness to the community, for it is by their efforts, principally, that this important work is to be carried to ultimate success. There is no scarcity of railway surgeons, nor is there a less demand for their services, but on the contrary, the steady advance of civilization requires more than ever before their assistance.

The collection of humanity in the sleeping cars and day coaches is a matter of great importance. When one considers the danger of infectious and contagious diseases, which in itself is a subject demanding careful consideration, bettering the sanitary condition of a railway coach is a serious problem to be solved. The time seems not far distant when the medical and surgical departments of railroads will be as important to the public as the equipment and the motive power of a train. The results of such departments, however, depend largely upon the energy displayed by the medical advisors of the companies.

The writer would urge the great responsibility which in a large measure, rests upon the medical profession to secure adequate means for the proper transportation of tuberculous subjects. Large numbers of tuberculous patients are continually being carried in ordinary cars to northern New York. What protection against infection is offered to the public when it is often necessary to share a seat with the unfortunate tuberculous patient who may deposit infection upon every occasion? When we consider these vast numbers carried yearly to the Adirondack region in the usual sleeping car with its plushes and draperies, the question arises, Is this the proper manner to convey persons thus affected? The State should compel a railroad to furnish a car prepared and used solely for this class of patrons. If such car had the constant attendance of a physician and a trained nurse, the patients would be better cared for and the result would be most effective in reducing the constant exposure to this dread malady, thus practically removing ordinary passengers from the danger of contracting the disease.

On one of the western railways a hospital-car service for the tuberculous has been inaugurated, and doubtless in time all roads over which large numbers of invalids travel will be similarly equipped.

These and other reforms can come only through the initiative or the influence of the railway surgeon, and in working to secure better hygienic conditions on the railway which he serves, the local surgeon will find a field as yet almost untilled, but one in which cultivation will bring an abundant harvest of good to humanity.

40 West Forty-fifth Street.

Congenital Hypertrophic Stenosis of the Pylorus.—C. T. Dent reports a case of this nature in which ten or twelve days after birth the symptoms began. The child was soon satisfied. The characteristic vomiting then commenced. Three or four feedings might be kept down, but then the stomach contents would be ejected. Various kinds of foods and medicines had no effect. When the writer saw the child, the symptoms were so pronounced that he decided on immediate operation. The child then weighed just over five pounds, and was fifty-one days old. The pylorus presented a very characteristic and strongly marked instance of congenital hypertrophic stenosis. The thickening was nearly an inch in length, and the tumor had the usual white appearance. Pyloroplasty was performed. The entire operation occupied twenty-five minutes. Rectal feeding was employed for the first twenty-four hours, small quantities of hot water being given by the mouth. The condition was not very encouraging, as the child suffered from constant diarrhœa due to enteritis. The stools were green and much of the milk was found undigested. After removal from the hospital, reports of the child's progress were unfavorable and it was finally readmitted. There seemed to be little or no intestinal digestion. The diet was changed and humanized milk was given, also raw meat juice (cold extract) and cream. The child began to improve, but it was not till the age of nineteen weeks that its weight was equal to that at the time of birth. The improvement was then more rapid and at the present writing it weights ten pounds. This case illustrates the necessity for early operation in this affection, and the writer believes that pyloroplasty is the operation of choice.—*The British Journal of Children's Diseases.*

MEDICAL SERVICE IN THE MERCHANT MARINE.

By JAMES FRANCIS DONNELLY, M.D.,
SURGEON IN THE TRANSATLANTIC SERVICE,
AND
FREDERIC GRIFFITH, M.D.,
NEW YORK.
SURGEON, FELLOW OF THE ACADEMY OF MEDICINE.

It has been well said that there is work enough for everybody on a ship, and the recent medical graduate or the landsman practitioner of riper years who turns to a sea life must quickly prove the truth of the statement. It is the purpose of this article to set down as clearly as possible the life of the medical man in the merchant and passenger steamship services, presenting its advantages and disadvantages. With pardonable pride in our national character, it may be stated that the American doctor has become known to the maritime world as being of the first rank. There are certain of the large steamship companies trading in all parts of the world whose home offices are abroad—addresses being given in detail further along in the article—who, with unfailing promptness, place American doctors applying for positions as surgeons aboard their ships. In the passenger service to and from American ports, the native born and educated physician again has the advantage in the race for place over the foreign medical man for the reason that the various steamship companies, whether of foreign or native ownership, are now coming to recognize the fact that the greatest number by far of travellers back and forth from America to Europe who use their ships are Americans. A large source of revenue to passenger steamship companies is derived from shipping emigrants, and our government is becoming more and more exacting as to the qualifications in determining who shall and who shall not be permitted to take up residence on our shores. The American doctor again is by nature better fitted to appreciate the proper construction of the laws upon this subject and likewise to secure every advantage for the company which employs him to look after the medical interests of these would-be citizens.

Inducements.—The attractions drawing a young medical graduate, or the older practitioner, to the sea may be manifold. Besides an innate love for the ocean, personal health may be an attracting force. Sea life is probably more generally healthful than any other existence. More particularly in its sedative effects is it valuable to one who has undergone the lengthened strain of four or seven years—as when academic and professional courses are combined—in college. The older practitioner, after years of uphill effort, securing only moderate success, as well as the one who works an unrelaxing round, may, too, be attracted seaward. Educationally, a method of broadening one's scope—so essential to the physician—by travel and study of the many phases of human nature which are thus continuously presented to the ship surgeon, is offered.

Application.—Having decided to seek the position of doctor upon a vessel with the object either of working his way about the world or to secure the coveted berth of surgeon on a liner, the proper method of procedure for the candidate would be to secure an introduction to the general agent of the company upon whose ship he desires to serve. While personal influence has weight, a well-written letter stating the qualifications of the aspirant and the announcement that the doctor will call around himself within a few days to present his case in person, will prove of equal value. Persistence in the matter is a most important quality, and a weekly call upon the agent subsequently soon attracts that official's attention and gives notice that the doctor is still alive and awaiting his opportunity to serve the company in an official capacity. While awaiting the chance to secure a regular appointment the candidate should visit the various ships in port of the class in which he intends to sail, and become acquainted with ship doctors, who will be found a most approachable set of men. By this means he is not only learning his way about a vessel, as it were, but will often chance to meet a doctor desiring a substitute. These changes are quickly arranged, and the candidate, to take advantage of such opportunities, must be prepared to embark upon shortest notice.

In the passenger service the American, Red Star, and Holland America lines employ American doctors almost exclusively upon their vessels. Other lines entering New York, particularly the German, are seriously considering the advisability of placing one or more American physicians upon their steamers. Freight steamers on call to a single port, or perhaps wending their way through many waters and visiting many countries before returning to the home port, which are known as "tramps," are sometimes more desirable as means of seeing the world. Probably the largest owners of steam vessels of this latter type are the "Elder Dempster S. S. Co.," sailing the Royal African Mail line of steamers, with general offices at No. 21 Water Street, Liverpool, England, and the "Elder Dempster S. S. Co.," Luisenhof, Hamburg, Germany, to whom applications may be sent.

Qualifications.—The personal qualifications of the individual who would be successful in his profession at sea are that, besides having a diploma from a reputable medical school of our country, he must be possessed of the manly quality of self-reliance, coupled with prudence in action. For he must remember that every doctor who enters a ship's company does so at a disadvantage. The popular idea afloat of the "ship doctor" is that being a failure ashore, he turns to the sea and would minister to jack-tar's ills. Government restriction in steamers of English registry running from England and between her colonies requires that the surgeon aboard must possess an English license if the combined number of crew and passengers is over one hundred persons. Dutch steamers have also government restrictions, but their enforcement is usually left to the steamship officials themselves.

Salary.—Payment for his services may be divided into two portions: first, the money received from the company as he stands listed upon the pay-roll, which includes his percentage from the sale of emigrant passage tickets. Second, the compensation derived from his patients, which may be truly termed the honorarium, as it may be in cash or a variety of articles. In the passenger service, the American, Red Star, and Holland America lines pay the highest cash salary, which is fifty dollars a month; from thirty to fifty dollars being the limits in regular passenger service. In addition to this, the doctor may count upon receiving from twenty-five to two hundred dollars extra from various patients upon a good trip—financially considered—during the "season," which lasts from about the end of May until July in the trips across from this side, and from the last of August up to October in the return passages. Besides money, the doctor is liable to receive anything which the recovered patient, returning home, believes might please the doctor. Or a monkey, a parrot, or a carved ship set sailing in a porter bottle by some old quartermaster, grateful but rheumatic, who does duty on the bridge, after having passed from a forty years'

service before the mast of sailing vessels, may be received. In freight steamers the compensation is less; twenty to thirty-five dollars per month being the limits of cash payments by the companies. Of course, aboard this class of steamers passengers are few and far between, and extra money derived from outside sources is likewise scarce. Sometimes, however, the doctor may have a chance to secure extra fees by being called ashore to see a case in a port far removed from civilization; as in the case of wealthy native planters along the West coast of Africa, who pay for treatment in ivory, skins, or nugget gold, which may readily be converted into cash upon reaching home. Work upon the African trading steamers is hard but pleasant. The doctor is the captain's "chum" and is given greater opportunities to gain a knowledge of the language, life, and character of the natives than can be afforded in any other vessels. A few companies allow a wine credit of a certain amount per month for the use of the doctor when entertaining friends or passengers. The doctor's room and office is usually combined, but is of ample size in most instances. The living is the best obtainable in the large ships styled "ladies of the ocean," and in all there is a plentiful supply.

Disbursements.—The necessary expenditures at sea include the personal laundry account, although some companies allow the doctor's washing to be done at their shore laundry. The doctor is usually expected to pay for his table and bedroom steward service. As the one may be a grateful patient and the other be satisfied by a gift from time to time of the doctor's cast-off uniforms, the money expense need not be large. Extra wine and cigars are charged to the doctor's monthly account, which is kept at the company's general offices.

Outfit.—The doctor's personal outfit should include a dress uniform and a working uniform with caps, with two or three sets of white duck uniforms for summer wear if the line of travel carries the steamer into torrid climates; a uniform overcoat; three sets of heavy underwear; six sets of light underwear; a dozen pairs of socks, heavy and light; two dozen collars; half a dozen shirts; a dozen handkerchiefs; cravats; three pairs of shoes; rubber overshoes; a pair of gum boots; storm coat (oilskin suit and sou'wester); toilet and shaving set; sewing bag (containing needles, scissors, buttons, thread). For professional work the doctor will require, besides a pocket surgical instrument case, the following instruments: hæmostatic forceps (4); scissors (curved); dissecting forceps; splinter forceps; grooved director (eyed); probe; spoon curette; scalpel; curved (sharp-pointed) bistoury; hernia knife; soft rubber catheter (No. 10 French scale); needles (curved and straight); catgut and silk (sterile packages). He will need a good practical work on medicine to which he may turn in emergency and secure a rapid recollection of his knowledge of the diagnosis, pathology, treatment, and prognosis of the disease he has encountered; also a similarly adapted work upon surgery, for when he is most in need of the knowledge he requires he will have least time at his disposal to spend in reading up a chapter upon the subject. Books upon the specialties may be added to his working library for secondary reading, but the chief reliance will be found to be placed upon the emergency textbooks of the character which has been described.

Rank.—The official standing of the ship surgeon which is accorded by the company's standard is that of second in command to the captain, and of equal rank with the first officer. The standing which he obtains in verity is that which he makes for himself after coming on board. While the crew and officers generally will receive him with but illy concealed feelings of disfavor, he may ere long make them all his friends and devoted admirers, if when starting out, and ever afterward, he conducts himself with the grace and dignity which our calling demands in dealing with laymen. While in ordinary times the doctor aboard ship is expected to attend strictly to his own business, in times of crisis his judgment in many matters outside of his regular calling will be tested, and well will it be if he is able to stand the trials, as after a collision, or in time of fire.

Social Life.—As in society in general, social circles on steamships are made up of rather well-defined cliques. The captain is supreme in the little circle drawn from the passengers which he gathers about him. It has been said that the social atmosphere of a ship depends entirely upon the temperament of the captain, and this is true to the extent that his character affects those of his officers and crew directly and through them cannot but react to a degree upon the passengers.

The chief engineer and the first navigating officer form a set by themselves. The other officers make up still a third, while the doctor either "cliques by himself," or may gain an equal footing in all the rest. While the purser is the recognized police official of a steamship, it is to the doctor everyone goes in time of difficulty, whether arising amongst crew, passengers, or officers. Ship doctors may be called upon at times to decide with the captain the advisability, and to share in the responsibility of placing a passenger, one of the crew, or an officer in confinement for misbehavior. Subsequent suits for damages are generally likely to follow such proceedings, and careful decision is required in these matters. The captain himself may, at times, be required to be subdued, as in a sudden attack of mania. The doctor in such cases must shoulder the entire responsibility for this restraining action. A carefully written statement corroborated by that of the crew, officers, and passengers would be required in such an event to protect the surgeon at the subsequent investigation by the company and the government.

Professional Relationship with the Crew.—The crew of a vessel are aboard of her for the object of working, and while the company provides medical attendance for those who are rendered incapable by accident or otherwise when pursuing the legitimate round of their duties, it expects the doctor not only to protect the interests of the crew against themselves, but to secure the best welfare and conduct of the ship by preventing individuals from taking advantage of this provision. The detection and prevention of malingering aboard ship is one of the surgeon's important duties. Alcoholic and venereal excesses are a common cause for disability amongst the men, and while the ordinary sailor has a childlike character in many respects, the doctor must not show too great a weakness in condoning these offenses, which clearly destroy a man's power to work two or three days out from every trip. Such a man, for a time, may be able to make up his deficiencies to the company for his days of idleness, but soon he is being employed at a loss, and it becomes the doctor's duty in the matter to make this fact known to his superiors. A doctor allowing himself to become too sympathetic may easily cause disorganization of the entire crew upon his vessel.

Passengers.—In his dealings with the passengers the doctor naturally stands as the mediator between them and the company as represented by the ship's crew and officers. Avoiding discussions in all matters,

fair judgment is required from him. While, after a few days out, the doctor may share the part with the captain of becoming a social lion, he must carefully avoid the appearance of becoming too popular. While he is the host for the nonce, he is still but the servant; his quickly-made friends will soon become forgetful of him, and if he would avoid discord he must prevent jealousy from arising in the breasts of his fellow-officers. A doctor who becomes a little abrupt during the extra bustle of changeable weather need not be surprised to find that the officials in the general office of the company have been notified by various tourists of his slights to the passengers. Ever mindful of the delicate position which he occupies, he will be required to exercise constantly all of his resources to cope with the arising situations. The surgeon may often serve his company and win their commendation by his power to prevent damage suits arising from accidents to passengers aboard his ship. With the exercise of a little tact a statement, which he may have in printed form, expressing satisfaction of the injured one or his friends with the treatment received will, after it has been signed, act as a deterrent when thoughts of securing legal redress arise in the minds of the patient or his family.

Steerage Passengers.—As the captain, chief officers, and doctor all receive a percentage of the ticket receipts for carrying emigrants, the interests of these people are generally well protected. From time to time, however, a magazine writer of more or less repute will travel "steerage" and upon his return, set himself the task of recounting his experiences, finding little to praise and much to blame in the manner of handling the immigrants. As a matter of fact, emigrants to-day travel to our country in far greater safety and in much more comfortable quarters than did the country's forefathers. Disputes must be adjusted and all disorder carefully repressed amongst the immigrants, for, in time of panic, their actions are the chief disturbing element aboard the ship. Sanitary measures must be instituted and carried out for the general good of the ship, and it is the doctor who is the chief organizer and executive officer in charge of these matters. His duties require that he make a careful examination of every emigrant passenger before he boards the ship for the purpose of detecting the unfit. The importance of this may be imagined, for if a single individual suffering from an incipient epidemic disease, such as scarlet fever, smallpox, measles, or yellow fever, were allowed to embark, the subsequent epidemic arising when at sea would cost the company many thousands of dollars' loss in quarantine expenses and fines, aside from the number of lives which might be sacrificed. Eye diseases are likewise of importance, as quarantine officers in the American ports are particularly charged to reject immigrants presenting chronic eye diseases, especially when of a trachomatous nature. As precautionary measures, candles and garlic are confiscated from the immigrants whenever found. A law of our government requires that all third-class passengers be vaccinated. This duty devolving upon the doctor, he finds it to his advantage to perform the work early in the voyage, else its performance becomes an almost utter impossibility, owing to seasickness if the weather becomes at all rough. It is therefore not uncommon for a ship doctor upon one of the large transatlantic liners to vaccinate from seven hundred to one thousand five hundred steerage passengers during the first day out from the foreign port. The implement by which this is accomplished consists commonly of a handle fitted with an attachment similar to the lead-holding device in the ordinary indelible pencil. By this means sharp, pen-like stylets are held in position while being used upon the patient's arm. Several stewards are engaged in loading the handles. The point after being dipped in the virus, provided in a receptacle at the surgeon's side, and applied, is discarded. Infection from one person to another is thus avoided. Daily inspection of the scars is a part of the ordinance, but this is impossible owing to the press of other work. Stewards are therefore required to check off the necessary inspections at the final sea inspection of the surgeon, which takes place a day or so before sighting land. But little trouble is experienced in carrying out the government health regulations save with that class of returning immigrants who, having spent some time in America declaring for citizenship, are returning after a visit to the fatherland. These persons, who are known as "one paper men," often resist and stand upon their rights as citizens to claim exemption. Notice to them, however, that they will be denied a landing if they do not submit to the laws of the country of their adoption quickly brings acquiescence. In general, these people have to be treated in strictest discipline. Knowing no law but that of the military force of their country, emigrants are quick to take advantage of apparent weakness upon the part of the doctor in the pursuit of his duties among them.

All classes of passengers will seek information as to the daily health report of the ship during a voyage. The uniform reply to such questions, whether from a steerage or first-class passenger of "All well aboard," will turn the questioner aside and quell the fears of the timid. Some steamship companies, when a death occurs from ordinary causes among the steerage passengers and which has been followed by burial at sea, tacitly expect the doctor to protect the corporation's interest by either making out a lax report or by omitting to mention the occurrence altogether in the papers to the quarantine officials. This saves time and money sometimes, but is perilous, for if the offense be detected, the company is not only heavily fined, but the doctor's character becomes henceforth suspicious.

Accounts.—The clerical work which the company and government regulations require from the doctor is such as relates naturally to his professional duties. His name must be attached to all official papers relating to the health of crew or passengers. His signature attached places him upon his honor as to the truth of the contents of such indentures.

Rejections of immigrant passengers at the port of embarkation with a statement of the cause must be officially noted by him. Sickness or death occurring amongst either crew or passengers must be also entered, accompanied by the doctor's descriptive statement.

Hospital Facilities.—The space accorded to the doctor in the treatment of the bedridden is limited to the patient's own berth in some steamers. Others have a special cabin or sick bay, far removed from the living quarters, where the sick may be isolated. Cabin passengers in time of epidemic are quarantined within their own staterooms. Steerage passengers, from whom most is to be feared, on such occasions are segregated so far as is possible in the necessarily limited space at command. Help from passing steamers may be secured in time of need according to the universal law of nations, whereby a transfer of patients may be effected or additional medical aid be obtained.

Supplies.—Modern steamers will be found equipped in most instances with an adequate supply of drugs, splints, dressings, and instruments suita-

ble for emergency or routine use. Many companies give the doctor free scope in his ordering, and are willing to purchase the best in the market. Besides the usual salves, ointments, and plasters, many of the most important drugs of the pharmacopœia, put up in tablet or compact form, are provided. Instruments include a set of sounds, tourniquet, general operating, anæsthetizing, obstetric forceps. The best medical journals published in our country are either subscribed for or sent gratuitously by the publishers to all of the ships upon the important lines.

Work.—An idea of the amount of work which may be crowded into the ship doctor's day of twenty-four hours may be obtained from the statement of a doctor aboard one of the crowded home-coming liners in the late summer of last year. This gentleman kept a partial account of one day's work during rough weather. He made a total of two hundred and eighteen visits to cabin passengers' staterooms in visiting patients, each one of which had to be seen to and treated with the same careful handling that the shore doctor employs. Office visits were not included in this computation. Besides the daily and nightly round of burns, scalds, and "cramp cases" occurring in the fire-room gangs, there are usually one or more individuals in the great company which a ship's crew musters who will require the doctor's continual attention. The populous steerage with its numerous progeny of children and mothers will demand a good share of the doctor's time, besides childbirth cases, averaging one or two in number every voyage during the season.

Seasickness, brought on most often by the over-indulgence in eating and drinking of the last days before sailing, with its usual concomitant condition of constipated bowels, takes up an additional share of the surgeon's hours and calls for a goodly supply of patience, castor-oil, epsom salts, calomel, and compound cathartic pills in the treatment, the general specific ordered being "champagne for the first passengers, and beer for the steerage." Local treatment which, though homely, yet finds the greatest favor in the ship doctor's eyes is the application of the so-called "sea-belt," which consists of a beer bottle wrapped up in a towel and bound in position tightly over the region of the stomach.

Besides his rounds of day and night "calls" the doctor attends, with the captain and chief officers, the daily inspection of the ship when at sea. Landing of the immigrants must be overseered by the surgeon, and their transfer to the government landing station, and subsequent inspection and distribution are all a part of his regular duty.

Moral Aspect.—Looseness of morals is proverbial among the seafaring, and it would not be a fair exposition to the young medical man desirous of taking up the career of the ship surgeon not to make some mention of the moral temptations to which his calling will naturally expose him. To understand the situation one must recall the factors at work. A great and various body of people are thrown in close proximity. Many of the travelling class are true "idlers," to whom the temptations for free and overeating and drinking with little or no exercise are manifest. The female population of a large steamer commonly contains one or more individuals whose morals will weaken under the strain and propinquity. As the doctor has the most intimate relations with the passengers, he of all the officers is most likely to be tempted. A man of weak character readily succumbs, is continually allured by the fascinations, and while perhaps never awakening to the fact becomes one of the class of doctors which the sailorman describes as "being all alike."

Summary.—*Advantages.*—By securing a position of surgeon aboard a steamship the young doctor will gain valuable experience in the study of human nature. He will be enabled to visit foreign countries and the different races of men. A week in each port, which is the usual stay of the great liners, will, however, prevent the surgeon from making extended trips from these ships. Probably six months or one year will suffice to enable the young medical graduate to gain a knowledge of sea-life as the doctor sees it. To the physician in search of health, if he be not too great an invalid, which would certainly handicap him for the activity of ship life, a valuable and inexpensive way is opened to enable one to secure a change of scene.

While the chance for social advancement may be easily overrated, the ship doctor is thrown in close contact and most pleasing intimacy with the most cultivated and highest types of our people, and the impressions which he makes will depend in great measure upon his demeanor and character.

Disadvantages.—The doctor aboard ship is considered an "idler," for while he may be oftentimes continuously engaged for hours or days he has periods of inactivity. The irregular life which is sometimes demanded is detrimental. There is a constant danger of contracting habits of intemperance in eating and drinking with a tendency to avoid active exercise beyond that required by professional duties.

Unless upon his guard, the doctor will become weakened in moral stamina by the life at sea, and lose ambition to advance to the heights in his profession.

PROFESSIONAL BY-WAYS OPEN TO MEDICAL WOMEN.

By EMMA E. WALKER, M.D.,
NEW YORK.

MUCH has been written in the last half century on the history of the development of the medical woman. We are carried back by hieroglyphics to ancient Egyptian times, when it was said that women were among the physicians and embalmers. Æsculapius was said to have had both men and women among his disciples. It is interesting to know that in ancient times the divinities who were especially devoted to the preservation of health were women. The Greeks worshipped Hygeia and built a temple to her. Mythology tells us that she was the daughter of the god of Medicine, Æsculapius. Another daughter of this old divinty was Panacea. The old Hippocratic oath was sworn by Apollo, by Æsculapius, the god of Medicine, and by Health and Allheal—Hygeia and Panacea.

It is said that the oldest prescription, which has been preserved, is in the Papyrus of Ebers. This prescription is one for dyeing hair. It is supposed to have been written by the mother of the first King of Egypt. The date of its origin is given as 4,000 B. C. It is merely one instance of many, showing the knowledge of drugs that women have had throughout the ages. In the Iliad we are told that when Patrocles, the friend of Achilles, was killed. Thetis made a post-mortem injection. She was one of the early women physicians in ancient Greece and she used antiseptic methods. So here and there down through the centuries we see brilliant examples of women who loved medicine and all that pertains to it, and made use of their knowledge for the benefit of mankind. This science appeals to women especially on account of their tender sympathy for

the sick and afflicted and of their instinctive desire to relieve pain whenever they see it.

In the Middle Ages there were on the walls of the University of Bologna five portraits of women who held chairs as professors there. In Germany the name of Frau von Siebold is distinguished. She held an honorary degree of medicine from the University of Giessen, given on account of her skill in obstetrics. For twenty-four years Mme. La Chapelle was at the head of La Maternité of Paris. One of our most famous obstetricians of the last century said that he had learned more from this brilliant woman than from any of the great teachers in Europe. She contributed a scientific work of great value on this subject which she so loved. Many other names of women who have become famous in this their chosen work are met with in literature. From the eleventh to the thirteenth century A.D., there were several renowned women lecturers in the famous school of Salerno. This school was known as the bridge between ancient and modern medicine. The medical profession has, indeed, a good proportion of women who have "added the incident of learning to the accident of brains."

The autobiography of Elizabeth Blackwell, the famous woman pioneer in medicine, is as fascinating as a novel. I have never read anything that gives a more vivid picture of the experiences which women pass through from the time when they determine to study medicine until they find themselves out in the world in its active practice. Dr. Blackwell speaks of her physical repugnance as a girl to dissection. On one occasion she says "a fellow teacher laughingly came to me with a dead cockchafer which had been smothered between her pocket handkerchiefs and offered it to me as a first subject for dissection. I accepted the offer, placed the insect in a shell, held it with a hairpin and then tried with my mother-of-pearl-handled pen-knife to cut it open. But the effort to do this was so repugnant that it was some time before I could compel myself to make the necessary incision which revealed only a little yellowish dust inside. The battle then fought, however, was a useful one. In my later anatomical studies I never had so serious a repugnance to contend with." Dr. Blackwell also met with the resistance of women to their own sex in the study of medicine. She had written in her girlhood days to Dr. Warrenton of Philadelphia, an old Quaker physician, for his advice as to her study of medicine. In his reply he says: "I have personally appealed to some of the most intelligent and liberal-minded ladies of my acquaintance, how far the services of a well-educated female physician would be appreciated by them. The response uniformly is 'Mrs. Gove and Mrs. Wright were unfit to teach, nor could any female become acceptable to us either as a teacher or practitioner of medicine.'"

The attitude of some of the men's minds to this brave girl who was seeking encouragement, is well shown in the following reply of Dr. Darrich: "The subject is a novel one, Madam. I have nothing to say either for or against it; you have awakened trains of thought upon which my mind is taking action, but I cannot express my opinion to you either one way or another. I beg you, Madam, distinctly to understand that I express no opinion one way or another; the way in which my mind acts in this matter I do not feel at liberty to unfold."

Dr. Blackwell relates an interesting incident of Fanny Kemble who was giving a series of Shakespearian readings in New York at that time, frequently offering her services for charity. Dr. Blackwell thought this a good opportunity for enlisting the noted reader's interest in her Infirmary, and with a view of getting her to give a public reading for its benefit she called upon her with a friend. The gifted woman was most courteous and listened to these physicians with much interest, until the statement was made that this Dispensary was conducted entirely by women. But when she heard this astonishing fact her eyes flashed, her expression changed, and she exclaimed—"Trust a woman as a doctor!—Never!"

Although literature teems with historic accounts of women in medicine very little has been written about the ways in which a woman may find employment in the line of her profession before her practice is lucrative enough for her self-support. We all, to a certain extent, are bound to judge of a subject according to our own personal experience. Though the professional life of the writer has been limited to New York City, it is probable that about the same factors exist in any large center in our country. For some time I have been interested in collecting facts concerning this line of work.

One of the first suggestions made to a woman who is seeking to support herself while waiting for patients is the work of abstracting and translation. Translation also offers the opportunity of making a few dollars, women receiving the regular rates for such employment. A few women whom I know have done indexing, research work for original papers, editorial work, and have even written papers for other physicians, but this requires special training and concentration; and sacrifice of many other things is necessary in order to achieve successful results, while the remuneration is very ordinary. There are several women's medical journals in this country conducted by women. This offers another field of work for the woman physician which she can carry along at the same time with her private practice.

I have before me a letter written by a well-known physician who has charge of a monthly magazine the plan of which is to have a quarterly review of the principal articles appearing in foreign languages on the subject with which this journal deals. He wished, as he said, to get some one who was well versed in German and French especially, to collect the material. The plan was as follows: The abstractor was to be supplied with the *Index Medicus* in which the most important articles to be abstracted were to be marked. In each quarter there were to be abstracted about one hundred articles; each article was to be summed up in a few lines, enough to make merely from about five to ten lines of print on a card in the regular library catalogue style. The letter continues that a rapid scanning of the article, gaining the conclusions, results, or leading ideas, is *all* that he desires. Certain articles were to be selected by the editor, while the other selections to make up the one hundred were to be left to the discretion of the abstractor. The interesting part of this letter is that which deals with the remuneration. The writer states that he is authorized to offer $15 for this work—that is, fifteen cents per card. He assumes that about ten cards can be written in an hour. In other words, this allows six minutes for looking over these journals, selecting the certain articles "left to the discretion of the abstractor," reading and translating this article, and gaining the "conclusions, results, or leading ideas." After this has been accomplished the whole is to be condensed and written out on the library catalogue card—six minutes being allowed for this whole process. Any one who has any knowledge of abstracting can imagine what this would mean to a young woman

physician who has had little or no experience in this work.

Not long since I was asked by a physician if I would write a lecture to be delivered before a well-known school of pedagogy. He believed that the remuneration would be about $25. He then proposed that I should write the lecture, while he would deliver it, taking $5 for the hour, and handing me the rest. In other words, I was to spend a suitable amount of time on the preparation of the lecture—probably from thirty to forty hours—have it typewritten, and receive $20 for the work, while he would have the distinction of having lectured before this school and would remunerate himself with $5 for his time.

These are just samples of the many experiences which women meet, although this inequality of compensation for women's work is by no means confined to women in medicine.

Miss M. Carey Thomas, President of Bryn Mawr College, in her address recently at the fiftieth anniversary celebration of the New York Infirmary for Women and Children, spoke of woman's position in the medical world. She believed that the ungenerous manner in which medical men have treated women in medicine, was due in a great degree to the fact that medicine is one of the most lucrative of all professions. The speaker said that men as a sex, although there have been notable exceptions, have disputed every step of the way with women, using as weapons ridicule, intimidation, and all the vested privileges at their command. The speaker continued that "such is women's aptitude and liking for medicine, and so great is the desire on the part of other women for their medical services for themselves and their children, that although this bitter opposition to women physicians has undoubtedly somewhat limited their numbers it has not been able to stop the practice of medicine by many women."

I was attracted by the speaker's idea that other women so greatly desire the services of women physicians. This is undoubtedly in many instances quite true, but the sentiment reminded me of a little interview that I had a year or two ago with the medical head of one of the largest insurance companies in New York City. This company makes the acceptance of women applicants for policies a prominent feature of their business. But in discussing the position of medical examiner the director told me, to my surprise, that it was these very women applicants who refused to be examined by one of their own sex. They demanded one of the men examiners. It is the old social problem of women not supporting each other. In all that vast company, with its numerous applications daily, there was not employment enough for more than one woman, and the amount that fell to her varied greatly. To obtain a position of medical examiner with one of the insurance companies, especially in large cities, is, I understand, one of the chief ambitions of a young man starting in medicine without an independent income. Opportunities of this kind are almost entirely denied the young woman who is starting out in her medical career. I cannot state with authority just how many insurance companies employ women, but their number is small. When applying for a position, the physician makes out an application blank or experience blank and makes an affidavit before a notary that she will be conscientious in her duty.

As to hospital positions, there are very few open to women. Indeed, as far as I have been able to ascertain by careful inquiry, there are only three hospitals at present in New York which offer any pecuniary compensation to women on their staff. One position is that of clinical assistant in the dispensary of a hospital. It includes the out-patient work for two hours a day, and has been held by the same woman for nearly six years. I have understood that there is one other clinic in town in which there is a small compensation given to a woman. In one other New York hospital there is a salaried position for a woman in which the duties consist in watching special cases while they are in the hospital, and in following them up after they have gone to their own homes. The work, as I have heard it explained, is not specially desirable.

Miss Thomas in her address related how in 1835 Dr. Elizabeth Blackwell was obliged to found the New York Infirmary for Women and Children in order to provide clinical work and hospital practice for women. She also emphasized the fact that now, fifty years later, this same infirmary and a small Women's Homœopathic Hospital are still practically the only hospitals where women may practise as internes or as visiting or regularly appointed dispensary physicians in New York City. It seems strange that in Great Britain so many more opportunities are given to women physicians. In London there are twenty hospitals open to them; in Glasgow 10; in Manchester 9; in Edinburgh 7; and in Dublin 5.

On first coming to New York I heard of a dispensary position in connection with a mission of a church in which the physician in charge received twenty dollars a month and was obliged to be there three times each day in order to attend to the patients. I know of one woman who was fortunate enough to have a friend who presented her with a fund to be used in private clinical work. There may be others doing the same, but this is the only one of which I know. This young woman was in charge of one department of one of the important clinics in a New York hospital and was thus qualified by experience to undertake this special work.

Another woman in New York City has charge of a training school for male nurses. This is also a salaried position, but it is one requiring the entire time and attention of the incumbent.

The Board of Health offers several positions for medical women, many of which, however, absorb the entire working time of the physicians. Applicants for these positions must first pass civil-service examinations. The routine has been explained to me as follows: The physician goes first to the commissioner's office to procure an application blank. This has to be signed by two citizens and a notary and forwarded to the commissioner. The applicant is then notified of the date of the examination, which lasts a full day. The percentage attained cannot be learned for a month. It takes several more months of waiting before an appointment can be obtained. The physician who told me of her experience waited a year. Here, however, is one position in which the duties and salary are the same for both men and women. Nevertheless, the department prefers men.

On the Health Board there are altogether eight medical inspectors who are women. These physicians receive one hundred dollars a month each for their services, and their hours average from nine to three o'clock. In the schools their work is laid out for them systematically, and account is kept of their hours and of the character of their work. They are furnished with case cards which they fill out, in order that the condition of the children may be followed up from time to time. The returns of the work soon show whether it has been conscientiously done. When the employment is taken by the year, two weeks is the alloted vacation. The work

f the inspector is to go from school to school examing children. Whenever any case is found in which moval from the school is necessary, the report ust be made by the physician. The children who ave gone through the routine examination two or ree times learn to present themselves in rotation ery quickly. Each child opens his mouth and icks out his tongue in order to give a good view f the pharynx; at the same time he takes hold of e lower lid and depresses it as he looks up to the hysician for inspecton. A well-known principal f one of the Manhattan schools told me the folwing incident: The superintendent entered the oom with a visitor who was interested in the schools. he minute the two appeared, the children dropped heir work and began to file by the visitor, head ack, mouth open, tongue out, eyelids dragged down. he visitor inquired what the proceeding might ean. "They think you are a new inspector," aid the superintendent. "The medical inspectors re frequently changed, so that when a stranger ntered the room, the children take it for granted hat a new examiner has appeared."

After the schools are closed there is the summer orps work. This consists chiefly in examining the enement-house children, in taking their histories, pecially those of infants under a year old, giving he mothers explicit directions as to the care of hese babies in summer, and in reporting those suitble for the fresh-air trips. Again these inspectors re assigned for vaccination work. One physician s appointed as division leader. He looks over he ground, and assigns the work to the other hysicians. The hours vary according to the ork, but in general are supposed to be from ine until four, with an hour for dinner. This ork on the Health Board does not necessarily exend consecutively over twelve months. As a natter of fact it continues generally for about ight months out of the year.

There is a new department just opened by the Health Board devoted especially to tuberculous atients. Tuberculosis in New York City is now ut on the plane of a contagious disease, and every hysician who is called to attend a tuberculous case s under the same obligation to report this patient o the Board of Health as he would be in the case f any other contagious disease. This work has grown o much that to the original corps of nurses several thers have been added. Two of these are women hysicians, but their work is purely that of nursing. Besides looking up these cases and reporting hem, they instruct the patients and their families n the modern methods of prophylaxis. For hose patients who are incapacitated for work they recommend hospital treatment. They look up all cases which have been reported in the last five years, in order to see what has become f them. The patients as a rule are visited once in about two weeks. These physicians receive seventy-five dollars a month, and seven hours of daily work is required of them, with the exception of Sunday and Saturday and legal holidays. On Saturday they are expected to spend three hours only. There are some medical inspectors in this work, and they receive one hundred dollars a month just like the inspectors of schools, and their duties are those of disinfection, fumigation, and renovation in houses where contagious diseases have existed. A woman physician told me that she had climbed sixty flights of stairs in one day doing health-board work. From careful study and investigation of this work it seems unquestionable that the compensation is not adequate to the amount of work done.

There are three women physicians employed in the research laboratories of the Health Board as bacteriologists and pathologists. Two of these women receive twelve hundred dollars yearly, while the third receives fifteen hundred. Their hours in general are from ten to five. As in other employment, there are many times when work is not completed within these limits, and in such cases of course the hours are longer than those just stated. They, too, must pass successfully the civil-service examination before being appointed to these places. I am told that physicians doing this work are unfitted for private practice. The strenuous duties incident to private practice absolutely unfit any physician for laboratory work. There is a chair of bacteriology and pathology in both the Lying-in and the Babies' Hospitals, held by a woman physician. These are salaried positions. This same physician also holds a scholarship in Bacteriology and Pathology in the Rockefeller Institute, I believe at seven hundred dollars a year. Last summer there were six women physicians employed by this institute to make a careful study of milk, especially as to its effects on babies. They each received sixty dollars a month for the time spent in the work. They then made reports of the effects of modified and unmodified milk, and of dirty and of clean milk. They watched the babies who were fed and reported their growth and the effects of their feeding and the condition of the mothers. They visited the homes from one to three times a week, as the condition of the baby required. This work continued for a few months. There is also a salaried position held by a woman physician in Bellevue in Bacteriology at a thousand dollars a year.

From an unprejudiced point of view it would seem that in all of this work anything that has a sufficient remuneration for support absorbs nearly the whole of one's time and strength, and there is almost nothing left either of time or strength to devote to the building up of the practice of medicine.

Laboratory work is also done here and there by physicians who have influence with those of standing. The results of this work mean a few dollars now and then. This income is of course irregular and spasmodic, as most phycisians prefer to send to an expert who devotes himself to this specialty alone.

There are a number of positions open to women on the staff of insane hospitals in this country.

Certain woman physicians have acted as book agents for medical books. I have never come in contact with a woman physician acting as an agent for drugs, but as many men physicians fill such positions, I do not know why they should not be open also to women. I have heard that there are a few women physicians who visit doctors in order to explain and exploit the virtues of new surgical instruments. I have, however, been unable to find any firm which admits employing women physicians in this way.

In the City History Club women who act as teachers receive one dollar an hour. When they act in the capacity of lecturer they receive five dollars an hour. Again there is a position in this club of "Graduate Guide" for which $3 is paid for conducting a two-hour party. Twenty-five per cent. of this sum, however, goes to the club.

Fresh-air work may also be obtained now and then by a woman physician. In this the physician examines children before they are sent to the country on the expeditions which are planned and paid for by various institutions. Some of the city papers have a fund for this purpose, some of the churches also do this work, and besides private funds are amassed to carry it on. In the Charity Organization

Society, examination of children for fresh-air excursions is paid at the rate of $2 for any number under twenty-five. I have been told that the St. Vincent de Paul Society pays $5 a hundred for examination of children in their Fresh-Air-Fund work. Another fresh-air fund is that of the St. John's Guild. Here women physicians are also employed.

I know of one woman physician who is director of one of the settlements, but this is not in the capacity of a physician, and neither has this young woman time for any outside work.

Some physicians have taken up the specialty of massage, believing in its great efficacy in many cases which come under their care. Others make use of their knowledge merely to train nurses for this work. I know of one physician who, in the midst of her work in physical culture, took up the study of medicine in order to make her chosen work more valuable.

Another way in which women earn money is to appear as expert witnesses in court cases for or against a railroad or a trolly company. The physician examines the plaintiff, and gives evidence in court, or makes a statement on which a compromise is based. If the woman has experience and standing, the compensation is very fair.

Various colleges for women in this country have a regular resident woman physician. There is so much work connected with some of these positions that no time is left for independent private practice. In others, however, the physician carries on both lines of work.

In certain cases women are called upon for professional work in private schools.

Another line of work is found in the lectures given under the direction of the Board of Education. Ten dollars is the fee for each lecture, and the same lecture may be repeated in different parts of the city. If the physician has influence she may also be appointed for a lecture now and then before working girls' clubs.

I know one woman physician who is doing tenement-house work. This is not professional work. It consists in the sanitary inspection of tenement houses. Abroad, this work has rather developed into a woman's profession. It is sometimes apportioned out by districts, and the inspector goes from house to house in her own district, making her examinations. The civil-service examination is necessary before one can be on the qualified list. One woman whom I know waited nine months for an appointment after she had waited several months for a notice that she had passed her examinations. The working hours average from nine to four o'clock, but there is a great deal of writing to be done at night. These examiners must be familiar with the Sanitary Code, the Tenement House Act, Plumbing, etc. After their examinations they report the necessity for repairs to the department. Sometimes they are assigned especially to houses where there has been contagion, in order to report upon their condition.

I have run across an interesting item in an article written in 1896 by a woman physician in which she states that the report from seventy-six women graduates of the Woman's College of Pennsylvania, gives the total income as $300,000 a year. Ten of the women receive between three and four thousand; five, between four and five thousand; three, between five and fifteen thousand; four, between fifteen and twenty thousand. Out of a hundred and thirty-eight, eleven had practised ten years and had failed to become self-supporting.

A recent writer on the subject of the "Successful Women of America," in reviewing the professions which seem to offer the greatest opportunity for success, gives the following list: authors, including novelists, essay writers, poets, historians, 487; artists, including painters, sculptors, engravers, etchers, illustrators, and architects, 103; educators, including lecturers, 91; journalists, including editors, critics, and correspondents, 65; actresses, 59; musicians, 43; social reformers, including club women and settlement workers, 27; physicians, 21; scientists, including naturalists, 17; ministers, including Salvation Army and missionary workers, 13; philanthropists, 12; librarians, 9; lawyers, 9; miscellaneous, 3. These figures amount to five more than the whole number of persons classified, because that number of women is represented as actively engaged in more than one vocation.

The treatment of women in the profession by their brothers, depends to a great extent, as far as I am able to judge, upon the woman herself. No one cares for a "manly woman," and it is, I am sure, from the fact that so many women in medicine have been lacking in feminine qualities and have aped the mannish attitude, that they have been disliked by others in the profession, and by the public in general. I have yet to see a womanly woman in the profession who is not admired by all with whom she comes in contact. This may not mean that she will become self-supporting in a year or two, for unless circumstances are peculiarly favorable, a young woman will have a very difficult time of it before she reaps sufficient income from her profession alone for her support. It is a long and hard road to travel from the beginning to the end at the best. It requires good courage, a cheerful outlook, and sound health.

It is easier to attain success in one of the small towns than in a large city, from a purely professional point of view, although what salaried opportunities there are, are to be found in the city. Difficulties for the woman physician have not all yet disappeared by any means. Medical women will always labor under the disadvantage of doing a man's work with interruptions that naturally fall in the daily life of a woman. Many a woman does not hesitate to take up part of a busy morning calling on her friend, the woman physician—who would not dream of interrupting her own husband in his office.

As to whether women are fitted to attain success in medicine depends to a great extent upon their preparation; it depends also upon what we mean by success. Success is by no means to be estimated by an annual income, although this is a necessary condition of good work. The woman who enters the profession of medicine for the pure love of it will feel that the truest success consists in being able through her work to give a helping hand to the women with whom she comes in contact. The woman physician is constantly appealed to by other women who are in trouble, it may be from one cause, it may be from another. These troubles are by no means always of a medical nature.

And if day by day, and at the end of her professional life, the woman physician can feel that she has been a help and comfort to those with whom she has come in contact, and if she feels that the world is really better for her having lived in it, she may be satisfied that she has attained the best kind of success in her calling.

29 East Twenty-ninth Street.

Englishmen Growing Taller.—There has been an outcry recently over the alleged physical degeneracy of the British, but statistics as to height do not appear to lend support to this gloomy view, for the average British man is said to be one inch taller to-day than his forbears were half a century ago.

LEGAL RIGHTS AND OBLIGATIONS OF THE MEDICAL PRACTITIONER.

By ARTHUR N. TAYLOR, LL.B.,
OF THE NEW YORK BAR.

THE physician, newly equipped with the medical knowledge and experience which in the light of the present is deemed adequate to enable him to enter upon the important work of caring for the health of his fellow-beings, and imbued with the importance of his trust, and the great diligence and care with which he must apply his skill and science, is apt to overlook the legal relations into which his work brings him with his patients and the State. This oversight is not so serious, however, as it might at first thought seem, for in the vast majority of cases the physician's professional and legal obligations run parallel, so that when he carefully and conscientiously gives his patients the best of his knowledge and skill, he is fulfilling the obligations imposed upon him by the law. It is desirable, however, that the physician should have at least a general knowledge of these legal obligations, and, in the course of his practice, it will be of much value to him to understand the rights which accrue to him through his professional intercourse with his patients. It is, therefore, the purpose of this article to encompass, so far as its limits will permit, the subject of the legal rights and obligations growing out of the relations existing between physician and patient.

The physician, because of the right granted to him by the State to practise medicine and surgery, is, in the absence of an express statute to that effect, under no obligation to exercise his professional skill upon whomsoever may apply for treatment, but may arbitrarily withhold his services, even though an adequate fee is tendered when the request for medical attendance is made. But the physician having accepted or agreed to attend a patient, it becomes his duty to continue the treatment and call as frequently and long as the nature of the case may require, and in determining when he may discontinue his visits he is required to use ordinary skill and care. This obligation may, however, be avoided by giving to the patient a reasonable notice that the services will not be continued, so as to enable the patient to procure the attendance of another physician. Should the physician discontinue his visits without first giving reasonable notice of his intention so to do, and at a time when by the exercise of reasonable care and skill he should know that further attendance was necessary, he would thereby become liable to the patient for all resulting damages.

The physician, or in fact any person acting as a physician, having undertaken to attend a patient professionally, the law immediately creates by implication a contract on his part that he is possessed of a "reasonable," "ordinary" or "proper" degree of skill and knowledge, that in the exercise of this skill and knowledge he will use reasonable and ordinary care and diligence, and in all cases of doubt he will use his best judgment.

These fundamental requisites are well recognized, but in their application nice questions frequently arise. There are certain well-recognized rules for determining what is proper skill and learning. Probably the first in order of these is that the physician's proficiency must be tested by the general principles of the school of medicine which he professes to practise. The meaning and justice of this rule is too manifest to require elaboration or illustration. The benefit of this rule has, however, been denied to a clairvoyant by the supreme court of Wisconsin, which, in a well-considered opinion, held that clairvoyants do not constitute a school of medicine, that there can be no school of medicine unless there are recognized rules and principles of practice for the guidance of the members whereby different members of the same school would prescribe substantially the same remedy for the same condition; that clairvoyants had no such recognized rules and principles but each practised after his own method, the only feature of their method of practice recognized by them in common being the manner of ascertaining the patient's condition. The second rule is that the physician's skill and knowledge must be judged in the light of the advanced state of medical science, so that it would not do for a surgeon of thirty years' standing to fail to operate in a suitable case of knee-joint disease because he was taught in college never to open the knee-joint, antiseptic surgery being then unknown; nor could a physician justify the administration of general anæsthetics in case of an operation on the eye, the use of general anæsthetics in the particular case being dangerous, by showing that authorities twenty years ago laid down the inflexible rule that an operation on the eye should never be undertaken without complete anæsthesia. And third, the skill and knowledge required of the physician shall be those ordinarily possessed by physicians practising in similar localities; thus the limitations or opportunities of environment are taken into consideration, and so a different standard would be imposed in case of a country physician with little or no opportunity to practise surgery being suddenly called upon to perform a difficult and complicated surgical operation, from that by which the skill of a physician practising in a large city and frequently taking part in such operations would be judged. This rule, it will be observed, is that the standard required is the skill ordinarily possessed by physicians practising *in similar* localities, not in his particular locality, otherwise it might be urged that when all in a given locality are ignorant quacks one could not be held wanting in skill because he possessed as much skill and knowledge as any of the others.

The physician bringing the requisite knowledge and skill to the treatment of a case, the next obligation imposed by the law is that he will use reasonable and ordinary care and diligence in its application, and the question of what is reasonable care and diligence must always be answered in the light of the circumstances and conditions of the particular case. Thus it frequently happens that the physician is called to attend a patient when the most casual examination is sufficient to inform him beyond question of the patient's condition and to enable him to prescribe with a moral certainty as to results, while on the other hand it not infrequently happens that a patient's condition is such as to require the most searching and continued examination to discover the malady or combination of maladies from which he is suffering, and after the physician has satisfied himself as to the diagnosis, the method of treatment may require equal thought and care. It is manifest that care which would have been adequate in the former case, would in the latter case be negligence, for which the physician would be liable for injury directly resulting.

The physician is not, however, necessarily required to use care and skill proportionate to the severity of the injury or disease treated, as such requirement would fall little short of guaranteeing results.

The requirement that the physician use proper and ordinary care in the exercise of his professional intercourse with his patients applies equally in determining when he may safely discontinue his

visits, to which reference has been heretofore made. It is also the physician's duty to use proper care upon discharging his patients to instruct them or their nurses as to the treatment or conduct to be observed during convalescence. A failure to exercise such care, resulting in injury to the patient, may render the physician liable in damages to the extent of such injury. And so must the physician use due care, in going from patients affected with contagious or infectious diseases to other patients, not to communicate such diseases; and again the question of what is due care is one to be answered in the light of the attendant circumstances—the character of the disease which is subject to communication, the susceptibility or condition of the patient to whom the physician goes after attending upon such case of contagion or infection—these are things which must be taken into consideration in determining what degree of care and precaution is requisite; in short, what degree of care and precaution would be exercised by an ordinarily careful and competent physician under the same or similar circumstances; such care is that which the law requires.

The physician also impliedly contracts with his patients that in all cases of doubt he will use his best judgment. This requirement is one which inures to the benefit of both the physician and patient. The physician is confronted by a complicated and serious case, perhaps one in which the recognized remedies cannot be used because of conflicting tendencies, or because of the peculiar condition of the patient, or perhaps because of an idiosyncrasy. At such a time, when the physician cannot act by precedent, but must do the thing, and perhaps without time for reflection, which his judgment tells him is best under the circumstances, it can but be of great comfort to him to know that if he uses his best judgment he is doing all that the law requires, and this knowledge will in turn leave the physician's mind as free as possible from worry and dread lest the results be deleterious, and so secure to the patient the very best services the physician is capable of rendering.

The physician must not, however, presume too much upon the "exercise of his best judgment," for its exercise is always based upon the possession of professional knowledge and skill without which there can be no "best judgment." In a case in which the diagnosis would leave no question in the mind of a capable and competent physician as to the patient's condition, and in which the method of treatment for that condition is well recognized and generally accepted by the profession, a departure from the established practice would be at the physician's peril.

The foregoing obligations of the physician are unaltered by the fact that his patient may be a charity patient, or that he may intend to make no charge; the only thing necessary to bring all these implied obligations into full force and effect is that the relation of physician and patient exists.

It will be seen that the physician does not impliedly contract that he will cure or even benefit his patients, but merely that he has reasonable and proper skill and knowledge, that he will exercise ordinary and proper care in the treatment of his patients, and that in all cases of doubt he will use his best judgment. These are the fundamental professional requisites prescribed by the law, and the physician who possesses and exercises them in all cases calling for their exercise will probably escape legal accountability for failure to obtain favorable results from the treatment of his patients.

Possessing and exercising all of these qualities, a physician may, however, through inadvertence or indiscretion, transgress the law, or may, without an actual infraction, come so near to the line as to be subjected to the annoyance and burden of defending a suit. Thus the question has frequently arisen whether the physician was authorized to perform a certain operation, the testimony of the patient being that he was to operate only if a specified condition were found and then the extent of such operation to be limited, while the defendant's testimony is that he consented to operate only with full discretion in the matter. In such cases it is a question of fact to be determined by the jury whether the physician has exceeded his authority and is liable. The question of whether a physician was authorized to operate upon a wife has several times been the subject of litigation, the husband testifying that the operation was contrary to his express instructions, but the evidence showing that the operation was understood and approved by the wife. In such cases it has been held that the instructions of the husband were immaterial, the wife having full authority to assent to and authorize an operation upon herself in the face of her husband's protests. And so a physician has been subjected to suit when he was called by one of his regular patients to examine a domestic for the purpose of ascertaining whether the domestic was pregnant, the domestic at first objecting to the examination, but finally submitting, though unwillingly.

The performance of an autopsy without consent from the party having authority to consent, has also been the subject of suits prosecuted successfully against physicians. The law is very strict in prohibiting such operations except when the decedent's condition was such as to render an autopsy necessary to determine the cause of death; and even in such cases the cautious practitioner will either procure consent to open the body, or, if practicable, turn the case over to the coroner. The parties from whom such a consent is properly obtainable are: first, the husband or wife of deceased; second, if no husband or wife survives, then the children; third, if there is no husband or wife and no child, then, first, the father, second, the mother; fourth, after them the brothers and sisters of the deceased; fifth, after them the next of kin according to the common law, to the remotest degree, according to the law of descent of personal property.

A peculiar case of liability arose some years ago in which a physician took a young unmarried man to a house where he was called to attend a confinement case, the circumstances being such that it would have been difficult if not impossible for the physician to have reached the house of the patient without the help and company of the young man. There being but one room in the house, the young man remained in that room with the patient and was present when she was delivered, the patient and her husband believing, as they testified, that the young man was a medical student. For this act the court severely censured the physician and affirmed a substantial verdict rendered by the jury.

The civil liability is not the only penalty which may flow from acts of mere inadvertence and indiscretion; such acts are frequently the foundation upon which criminal prosecutions and sometimes convictions are based. The space allotted to this article will not, however, permit the consideration of this phase of the physician's liability.

The physician having been called to attend a patient, and having responded, it becomes pertinent to inquire what rights inure to him by virtue of such professional relations and how he may, in case of necessity, enforce them.

Upon responding to a call to attend a patient the physician thereby becomes entitled to the regular fees for making a call, even though the patient may

have so far recovered from his illness as to render the visit unnecessary or even though another doctor may have been subsequently called and rendered the desired services, there being no question of negligence or delay precluding the right to such fee. He also becomes entitled to a like fee for each subsequent visit which, by reason of the character of the case, he deems it necessary to make.

The amount of fee to which a physician becomes entitled by reason of such attendance is a matter governed by custom and practice, the custom of the particular locality governing. If the customary price for a visit is one dollar, then a physician who, in response to a request for services, calls upon a patient with no understanding as to the amount to be paid or received, becomes entitled to one dollar. If any physician should be dissatisfied with such rate he could, of course, by express understanding or agreement with his patients, fix a rate to suit his ideas.

The rate of fees for performing operations is also subject, to a certain extent, to the custom of the locality, though the character of this class of work is such that the price cannot be thus regulated to such a degree as the fees for ordinary medical attendance. An exception to the rule that local rates for fees, in the absence of express agreements fixing other rates or amounts, binds the physician, is found in cases in which physicians or surgeons from a distance are called because of their peculiar fitness to attend or operate upon a patient. In such case the fee chargeable is properly based upon the rate usually charged by such physician or surgeon.

In case of consultation, the patient without express agreement becomes liable to pay the consultant's fee; and this rule is so firmly established that an agreement between the patient and the attending physician that the attending physician will pay such fee will not release the patient from paying the consultant unless the consultant is informed of such arrangement.

The physician having earned a fee and having had his request for payment refused, it becomes necessary to determine whether to resort to suit to enforce the payment. To determine this question it is necessary to consider the several steps of making proof and the several questions which may be raised.

First, is the physician a legally qualified practitioner? In all States where the question has been passed upon except the State of Missouri, it is held that one not a legally qualified practitioner may not sue; therefore a negative answer to this question, except as to one practising in Missouri, is equivalent to the determination that there is no cause of action, and such disability to recover applies not only as to professional services but as well to claims for medicines furnished to the patient.

The foregoing question having been answered in the affirmative, it then becomes necessary to determine whether the claim is barred by the statute of limitations. As these statutes differ more or less in the several States, this question can be answered only by recurring to the statute of the particular State in which the cause of action accrued.

The next step is the matter of proof of the physician's license. This is a technical matter which may best be left entirely to the counsel.

The next step is the proof of employment: if the physician is employed by the party to whom the services are rendered or by a party who is under obligations to provide medical services for the patient, then proof of such employment is not necessary. Under such circumstances proof that the services were rendered and accepted will be sufficient; but if the employment is by some third person who is not primarily liable for the services rendered, this step in the case is very important and the character and sufficiency of the proof are matters to be submitted to counsel.

The next step in proving the claim is to show the services rendered; this is a step which is frequently if not usually fraught with difficulty.

Laws have been enacted in many States to the effect that a physician shall not be permitted to testify to information which he shall have acquired in attending a patient in a professional capacity and which shall have been necessary to enable him to act in that capacity. Among these States are: Arizona, Arkansas, California, Idaho, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, Nevada, New York, North Carolina, North Dakota, Ohio, Oklahoma, Oregon, Pennsylvania, Utah, Washington, Wisconsin, and Wyoming. This inhibition, it is held, is not waived by a plea of general denial on the part of the defendant, the effect of which is to render it necessary for the physician to prove all of the facts upon which he is to recover. This places the plaintiff in a trying situation, where he cannot testify with any degree of detail regarding the services rendered, and yet he must prove the rendering of the services or fail in his suit. Under such circumstances he will, to use the words of Mr. Justice Hait of the Court of Appeals of New York, be permitted to "testify to his employment, the number of visits made, to the examinations, prescriptions and operations, and if the defendant objects to his describing them, he may testify as to their value."

In giving testimony in proof of the services rendered it will be difficult, if not impossible, when considerable time has elapsed since the rendering of such services, for the physician to testify with sufficient certainty and accuracy as to the items of service, without having recourse to his books of account. At such times, if he made or saw the entries made in his books of account when the facts were fresh in his mind, and remembers that it then stated the facts correctly, he may refer to the books to refresh his memory. Subject to certain limitations, the books in most of the States are themselves admissible as evidence of the facts stated in them. This is, however, a matter which is subject to limitations and rules differing more or less in the several States; for instance, in New York the books of account of a physician will be admitted as evidence, there being no objection to them upon the ground that they disclose privileged communications, upon his showing them to have been his regular books of account, that he kept no clerk who was familiar with his business and competent to testify regarding the facts stated in the books, that some of the work or services charged was performed, and that he kept correct accounts. In many of the States it is necessary that the books shall be books of original entry. The question of admissibility of evidence in support of the physician's claim is a technical one upon which counsel must pass, therefore it is not thought advisable to go into the question in great detail. A few words may, however, well be devoted to the manner of keeping books of account. It may upon the trial be necessary to state more or less particularly the nature of each service rendered, therefore the book of original entry should be so kept that by referring to it years after the services charged were rendered, the physician may be able to testify particularly as to each item, and if permitted, describe the character of the services rendered. It must be remembered, however, that in most States information gained while attending the patient professionally is

not permitted to be disclosed in court, therefore in such jurisdictions a book of accounts, which plainly and explicitly states the character of ailment for which the patient is treated, will manifestly be inadmissible. It has been suggested by the writer of this article* that this difficulty may be overcome if the physician will adopt a code of arbitrary signs and characters whereby he may be able to describe the ailments of his patients and the character of the services rendered to them in such a way that this portion of the information contained in the book will be wholly unintelligible to all others than himself, and therefore not subject to the objection that it discloses confidential communications. If the accounts be kept in this way, each item being charged separately under the date upon which the service was rendered with a specific sum charged after such item, then the book will be admissible to show dates and amounts, and may also be used on trial by the physician for the purpose of refreshing his memory, and enabling him to testify in detail so far as the law of the particular State will permit.

The foregoing anticipates that the party against whom the suit is brought is still living. Should he be dead and a suit against his estate become necessary, the situation becomes further complicated by the fact that the physician will not be permitted to testify as to any transaction with deceased, relative to the subject matter of suit. In such a case, there will be nothing for him to do but submit his books and corroborate them by the testimony of some one else, and indeed, whether the books will be admitted in such a case is not clear, there being conflicting decisions upon the question. When the books are held admissible, and are not so kept as to show the nature and date of each service rendered and amount payable therefor, or when such information is partly recorded in characters unintelligible to others than the physician, then they are subject to the objection that they are too indefinite to prove the account, and are of no value except when supported by strong corroborating evidence. If, on the other hand, the books contained all of these necessary facts in characters intelligible to the court, they would, in States recognizing professional communications as privileged, be wholly excluded upon objection by the opposing party. In cases of this sort the person most frequently capable of corroborating the physician's books and testimony is his wife; but is her evidence competent? At common law the wife was not permitted to testify for or against her husband in a suit to which he was a party. This rule is now altered by statute in most States but still remains the law in a few. In those States in which the wife is competent as a witness under ordinary circumstances, the courts are divided upon the question whether she will be permitted to testify when the other party to the suit is dead or insane, the courts of Maryland, Mississippi, New Hampshire, and New York holding that she will; the court of Nebraska indicating that such ruling will be accepted; the courts of Illinois, Indiana, Iowa, Maine, Pennsylvania, and West Virginia holding that she will not be permitted to testify.

Fortunately it is infrequent that suit must be resorted to for the collection of claims from the estates of decedents, but to collect a claim from such estate it is usually necessary to comply with the practice and forms of the particular jurisdiction in which the estate is being administered.

The limits of this article will permit of but a brief outline of the method of presenting a claim for payment and a hasty examination of the considerations to be entertained in determining whether to resort to suit.

Ordinarily the first step in the administration of an estate is the application for letters of administration, or, where there is a will, the application for probate and for letters testamentary. Upon the issuance of letters of administration or letters testamentary it is proper for the claimant to present his claim to the administrator or executor as the case may be. Shortly after issuance of letters to the administrator or executor he may, and usually does, under direction of the court, advertise for the presentation of claims against the estate, fixing a date within which all claims shall be filed. In some jurisdictions all claims which are not filed within the time limit are forever barred, while in other jurisdictions such claims merely forfeit the right to share in the first distribution of assets, but may follow any remaining assets.

The manner of preparing the claim for presentation should next be considered. The required form is not the same in all States, yet if the physician will prepare his claim after the following directions it is believed that he will have complied with the strictest requirements of any State. The claim should be reduced to writing and should describe the general nature and amount and value of the services with as much particularity as possible. If a note or other instrument has been given, then a copy of it should be attached. Claims for services should be verified on oath, the oath containing substantially the following:—that claimant is a physician and surgeon, and has been duly licensed under the laws of the particular State to practise medicine and surgery; that the annexed account was for professional services rendered to decedent or to some one for whose medical attendance he may have been responsible, as the case may be; that the amount owing for such services is————dollars, which is a true and just indebtedness after allowing all true and just credits, deductions and set-offs, and it is now due and unpaid.

The claim having been presented it will then be acted upon by the executor or administrator, who will allow it in whole or in part, as he is convinced of its validity and justness, or will reject it as a whole. If rejected, it is in most States, provided by statute that the claim will be barred in a short period of time, ranging from three months to one year, within which time claimant may commence suit on the claim.

Among the questions to be considered in determining upon the advisability of suing such a claim are: First, whether the claim is a valid claim against the estate. This is a question involving the consideration of the many defences which may be raised by a living defendant, and a few others which peculiarly appertain to claims against estates of decedents. For instance, the physician's bill for services rendered a deceased wife should be paid by the husband and cannot be enforced against the wife's estate unless it be shown that the husband has no property with which to pay the claim; or when services were rendered without intention of charging therefore, the physician expecting that he would receive a legacy sufficient to compensate him for all such services, the failure to receive such legacy will not enable him to maintain a claim against the estate. If, however, when such services are rendered there is a mutual understanding that the physician is to be compensated by legacy, then the failure to make such bequest will enable the claimant to maintain a claim for such services. Also in case of services rendered to members of one's family, there is a presumption that they

*The Law in Its Relations to Physicians, p. 204.

were gratuitious, but this presumption may be overcome by proof that the services were rendered under an understanding that they were to be paid for, or under such circumstances as to show that when they were rendered the parties contemplated a pecuniary compensation therefor. This presumption becomes weaker as the relationship of the parties becomes more distant.

Second, whether the claim is susceptible of proof. The law relating to this question has been heretofore examined.

Third, the solvency of the estate. At common law claims presented against an estate and allowed were payable in the following order: (1) The necessary funeral expenses. (2) The necessary expenses of administration. (3) Debts of record due the crown. (4) Debts of record due the subjects, which include judgments, decrees, statutes, and recognizances. (5) Debts by specialty founded upon a valuable consideration, that is those debts arising out of contract under seal. (6) Simple contract debts based upon valuable consideration. (7) Voluntary bonds or covenants. (8) Other voluntary debts. According to this scheme it will be observed that the physician's bill would belong to the sixth class unless he had secured a bond in liquidation of the account, in which case it would be advanced to the fifth class, or unless he had reduced it to judgment, when it would become a claim of the fourth class.

This order has, however, been altered in every State, the most common order now existing being the following: (1) Funeral expenses. (2) Expenses of administration. (3) Expenses of last illness. (4) Judgments (abolished in a number of States). (5) Public debts (this in many States has a prior rank in the scheme). (6) Simple contract liabilities.

If an estate is solvent it will, of course, pay all of the claims of all of the classes, but in case it is insolvent, then it will pay the classes in their order to the full extent of the available assets, the class last reached receiving whatever there may be left and all of the creditors of that class getting a *pro rata* share of such amount. Therefore in determining the question of solvency, so far as the particular claim is concerned, it is necessary to determine, first, the class to which it belongs, and, second, whether there are assets enough to pay all of the claims of that and the preceding classes.

It will be observed that the scheme adopted by most of the States recognizes a class not recognized by the common law scheme, that is, the "Expenses of the last illness." The question of what constitutes the expenses of the last illness is often a very nice one and one which has given rise to many bitter contests. The general tendency of the courts is, however, to recognize all services rendered to the patient in attendance upon him for the disease of which he died as "expenses of the last illness," even though such attendance may have extended through a long period of time. In some cases, courts and juries have gone so far as to hold that services rendered through the year preceding death were "expenses of the last illness."

All of these questions being answered in the affirmative, the physician is then justified in determining to enforce his claim by suit, but as the consideration of some of these questions requires the exercise of judgment, fortified by an understanding of the technicalities of the law, the conclusion should be reached only after a conference by the physician with his counsel, in which all of the facts and circumstances are fully and frankly laid before the counsel.

12 Nassau Street.

STATE MEDICAL PRACTICE LAWS.

By R. J. E. SCOTT, M.A., B.C.L., M.D.,
NEW YORK.
GYNECOLOGIST TO THE DEMILT DISPENSARY.

The medical student, after four years of hard work, and passing his examinations, receives his diploma and becomes a Doctor of Medicine. It is somewhat humiliating to him to find that this diploma and title give him absolutely no right to practise medicine. He has now to satisfy the requirements of the Board of Examiners of the State in which he desires to locate. These State boards are very necessary, and, serve a threefold function: (1) To protect the public from quacks; (2) To conserve the interests of the practitioners already settled in the State; (3) to keep out incompetent practitioners.

The requirements of these State boards may be classified under four heads: (1) General and Preliminary, dealing with age, moral character, residence, and possibly citizenship in the United States; (2) Preliminary or Academic Education; (3) Medical Education; and (4) The Medical Examination that has to be passed.

The requirements under (1) generally give no trouble. (2) *General Education;* This differs very materially in the various States and Territories. Some States require either an academic degree, or at any rate a full four-years' course in a high school or substantial equivalent; while other States are content with legible handwriting and fair spelling. (3) *Medical Education:* The requirements here are nearly as varied as those for the preliminary education. Most of the States now require a full four-years' course in a first-class medical school; some States still require only three years; one of two States seem content with even less; and it would be hard to say with how little real medical education a license could be obtained, if only due care were observed in the selection of the State in which to practise. (4) *The Examination:* Every State has its own idea of what is right and proper here. In most of them a good, fair, practical examination is put up; and a properly qualified student will have no difficulty in passing it. The number of papers may vary anywhere from half a dozen to a score, but it is not to be inferred that the examination in the State with twenty papers is more difficult than that in the State with only six. Some State boards manage to compress all the main subjects of a medical education within the compass of from seven to ten papers; while others delight to spread themselves out, and set a separate paper on every specialty, as if they were making a bid for universal specialists.

If at any time the practitioner wishes to move from one State to another, he has again to satisfy the medical examiners of the State he desires to enter. Though at first sight this seems an intolerable hardship, it will, on a careful investigation of the facts mentioned above and a perusal of the various requirements given below, appear no more than right. Naturally, the States whose requirements are the most slender, are eager to "exchange" or "reciprocate" with those that require more. Reciprocity will come, sooner or later, but the problem is a large and complex one, and this is not the occasion on which to discuss it.

The object of this paper is to place before practitioners a résumé of what the different States require. The information given will be on the four topics stated above, with further mention of any reciprocity that may exist between the different States. All points bearing on the laws governing the constitution of the Board of Examiners, whether the members are appointed by the governor of the State or by the medical societies, prosecution for

illegal practice, etc., will be omitted, as not of general interest.

As a general rule, the student who has taken an academic course for four years in a high school and then spent four years of medical study in a recognized medical college, will have no difficulty in gaining admission in any State. Those who have not this standard of qualification will see what States they had better avoid.

The information given is, as far as possible, up to date, but, in every case, would-be applicants should apply to the secretary for the latest requirements and at the same time try to obtain samples of the questions that have been used on former occasions. These questions will show the scope of the examination better than anything else.

Passing examinations is a kind of gymnastics that belongs to youth, and to youth only. These examinations should be taken at the earliest possible date. The day a man leaves college he has, probably, more of that class of "knowledge" which delights examiners and is of little use to anyone else, than he is ever likely to be possessed of again.

A word about preparation for these examinations. The recent graduate has modern books, and in all probability he will experience no difficulty in reviewing the various subjects required of him. If he has neglected some subjects (say anatomy and chemistry) for a couple of years, he will certainly have to go over them carefully. So, too, if the State board that he has to face is one that peddles out all the specialties over quite a series of papers, he will need some reliable guide to steer him past that portion of the track.

The practitioner who has exchanged vast quantities of theoretical knowledge carefully acquired at college, for the more useful but (to examining boards) less satisfactory practical knowledge, will need all the help he can get; and to some or all of these classes, the following list of books will probably be of service. In compiling this list, we are mindful of the fact that many men have as good and perhaps even better books with which they are already familiar; such men would be unwise to exchange the tried and trusted for the new. But those who are rusty, or who have but little time, will find here books which the writer has proved, from a five-years' experience in preparing men for these examinations, to be admirably adapted for the purpose. In every case the smallest book compatible with safety has been mentioned. It is well to remember that many books, very serviceable to the practitioner, are almost useless for examination purposes. For the benefit of students and practitioners preparing for examination, the present writer has compiled a series of volumes of questions and answers covering nearly all the subjects required; this is referred to as the State Board Examination Series,

Anatomy,	Nancrede's Compend, or Potter's Compend.
Surgical Anatomy,	Treves.
Physiology,	Kirkes.
Chemistry,	Bartley, or Simon.
Surgery,	DaCosta, or Rose and Carless.
Obstetrics,	King, or Warren.
Practice,	French, or Hughes, or Stevens.
Pathology,	Green or Thayer.
Hygiene,	Egbert.
Medical Jurisprudence,	Chapman or Reese.
Toxicology,	See Chemistry and Medical Jurisprudence.
Gynecology,	Penrose.
Bacteriology,	Archinard.
Eye,	May, or Gould and Pyle's Compend.
Ear,	Buck's First Principles.
Nose and Throat,	Coakley.
Skin,	See Practice (Hughes or Stevens); or Schamberg's Compend.
Diagnosis,	Gibson and Russell, or Hare.
Materia Medica and Therapeutics,	Hare, or Stevens, or Potter.
Histology,	See Physiology.
Nervous,	See Practice.
Mental,	Hughes' Practice.
Physics,	Brockway.
General,	The State Board Examination Series, referred to above or Gould and Pyle's Pocket Cyclopedia.

Résumé of the Requirements in the Different States and Territories.

Alabama.—All persons proposing to practise medicine in this State must undergo examination, irrespective of any diploma they may hold or certificate obtained elsewhere. Applicants can be examined either by the State Board of Examiners or by a county board of examiners. Non-graduates can be examined only by the State board, but graduates of medicine can be examined by either State or county board.

In order to appear before a county board of examiners an applicant must hold and present a diploma from a reputable medical college, the State Medical Association determining the question of reputability. Non-graduates can be examined, but they must apply to the State board. An applicant rejected by a county board cannot obtain a second examination by the same or any other county board until after the lapse of twelve months, but he may forthwith appeal to the State board and obtain a new examination.

The examination is in writing, and comprises the following subjects: Chemistry, Anatomy, Physiology, Etiology, Pathology, Symptomatology and Diagnosis of Diseases, Obstetrics and Obstetrical Operations, Gynecology, Minor and Major Surgery, Physical Diagnosis, Hygiene, and Medical Jurisprudence. In order to pass the examination, the candidate must obtain a general average of 75 per cent.

An examination by a county board can be obtained at any time; examination by the State board can be obtained by applying at the office of the State Board of Health, Montgomery, between the first and sixth of any month.

The fee for the examination is ten dollars, and for registration, one dollar.

There is no reciprocity.

Chairman of the State Board of Medical Examiners is W. H. Sanders, M.D., Montgomery, Ala.

Alaska.—There is no medical-practice law in this territory, the only restriction being that itinerant physicians must pay a license fee of $50 a year.

Arizona.—Every applicant must be over twenty-one years of age, of good moral character, and a *bona-fide* resident of Arizona. A recent law provides that no person shall receive a license to practise medicine within the territory unless he or she shall have: *First:* Obtained a diploma to practise medicine, regularly issued by a lawfully organized medical college, and, *Second:* Obtained a certificate entitling him or her to practise medicine, as prescribed in the Revised Statutes of Arizona, 1901, or shall have passed a satisfactory examination prescribed by the provisions of an act to regulate the practice of medicine in the Territory of Arizona, approved March 18, 1897; or, *Third:* Practised medicine within the Territory of Arizona continuously for five successive years preceding the date fixed for the taking effect of this act; or, *Fourth:* Upon examination by the Board of Medical Examiners of Arizona, shall show to the satisfaction of the board that he or she possesses sufficient knowledge and skill to practise medicine.

All recent graduates will have to pass the examination.

Examinations consist of five or ten questions each in Anatomy, Physiology, Chemistry, Materia Medica and Therapeutics, Obstetrics, Gynecology, Practice, Pathology, Surgery.

The applicant must obtain a total average of 80 per cent., provided that in no branch shall the percentage be less than 70, except in Practice, Obstetrics, Gynecology and Surgery, in which branches the minimum is placed at 85 per cent. The fee for examination is $10 and for license $2.

Examinations are held at Phœnix, on the first Monday of January, April, July, and October.

Secretary of the Board of Medical Examiners, Wm. Duffield, M.D., Phœnix, Ariz.

Arkansas.—Applicants must be of the age of twenty-one years and must pass an examination in the following subjects: Anatomy, Physiology, Chemistry, Materia Medica and Therapeutics, Surgery, Practice of Medicine, and Obstetrics. The questions are elementary and practical. If, in the opinion of the board, the applicant possesses the necessary qualifications, a certificate will be issued to him. The fee for examination and registration is $10.

Examinations are held four times a year, on the second Tuesday in January, April, July, and October; and at such places as a majority may agree upon.

Secretary of Board of Examiners, Dr. J. P. Runyon, Little Rock, Ark.

California.—"The medical law and the rules of the Board of Medical Examiners require an applicant to possess a diploma issued to him by a legally chartered medical college, the requirements of which are in no particular less than those prescribed by the Association of American Colleges for that year. The applicant must produce to the board such a diploma, and an affidavit stating that he is the lawful possessor of said diploma. Such affidavit must be taken before any person authorized to administer oaths (blanks will be furnished by the secretary of the board). The applicant must furnish satisfactory testimonials of good moral character. In addition to the above, every applicant must be examined on Anatomy, Physiology, Bacteriology, Pathology, Chemistry and Toxicology, Surgery, Obstetrics, Materia Medica and Therapeutics, Theory and Practice of Medicine. There will be not less than ten questions on each subject. The examination must be in whole or in part in writing, and in the English language. A general average of 75 per cent. must be attained." The fee is $20.

Examinations are held on the first Tuesday of April, August, and December, in San Francisco.

Reciprocity, none.

Secretary of the Board of Medical Examiners, George G. Gere, 825 Market Street, San Francisco, Cal.

Colorado.—Graduates of recognized medical schools are registered without examination. For definite information as to what schools are recognized apply to the secretary. Those graduating after 1899 must have had a full four-year course in a medical college with the standard of requirements recognized by the Association of the American Colleges. Physicians possessing such qualifications, in order to practise medicine in Colorado, must appear in person before some member of the Board of Examiners (preferably the secretary) and fill out an official application. This must be sworn to before a Colorado notary public, or the president of the board, and sent, together with his diploma and the fee ($5), to the secretary of the Board at Denver for filing and presentation to the board at their next regular meeting. Applicants must produce documentary evidence of general preliminary education, equal to a four years' high-school course.

For other physicians, and undergraduates, there will be an examination in Anatomy, Chemistry, Physiology, Pathology, Surgery, Practice of Medicine, and Obstetrics. The fee for the examination is ten dollars.

Regular quarterly meetings of the board are held at Denver on the first Tuesday of January, April, July, and October; examinations are held at the office of the secretary, two weeks prior to the regular quarterly meetings of the board.

Reciprocity, none,

Secretary of State Board of Medical Examiners, S. D. Van Meter, M.D., Denver, Col.

Connecticut.—All candidates must be graduates of some reputable medical college and must present their diplomas (or a certificate from the dean of the medical college) for inspection, to the secretary of the board at the opening of the session. All candidates must undergo the regular examination conducted in writing, and consisting of ten questions each in Anatomy; Surgery; Materia Medica, including therapeutics; Practice, including pathology and diagnosis; Obstetrics, including Gynecology; Physiology; Medical Chemistry, and Hygiene. In order to be admitted to practise, the applicant must obtain a general average of 75 per cent. In no branch shall his percentage be less than 60, and in Practice, Obstetrics, and Surgery, the minimum requirement will be 65 per cent." The examination fee is $15.

Examinations are held on the second Tuesday of March, July, and November, at the City Hall, New Haven, Conn.

Reciprocity is permissible with States in which the examination is of the same kind and of as high a grade as that of Connecticut.

Secretary of the Medical Examining Committee, Chas. A. Tuttle, M.D., New Haven, Conn.

Cuba.—The graduate of a foreign school must present his diploma for registration to the medical department of the University of Havana. If this diploma is approved the candidate will be admitted to examination upon payment of a fee of $35. The applicant must undergo a theoretical examination, in which the professors constituting the board may question him, *ad libitum*, upon all matters that are subjects of study in the University course of medicine. The following day the examination will consist of two parts: The first part will consist of the clinical examination of a patient, in whose case the applicant must make a diagnosis, in the presence of the board, as well as a prognosis and plan of treatment. In the second part he must describe the method of performing an operation, selected by chance from the "*Cuestionario de Medicina Operatoria*" used in the examination for the degree of licenciate in medicine, in accordance with existing rules. The last part of the examination will take place on the following day and will consist of the writing of a thesis upon a subject selected by lot from ten proposed by the professors. For the preparation of this thesis, he will be allowed five hours, during which he must not communicate with any one, the board taking such measures as it may deem necessary to secure this end. After writing this thesis, the applicant must read it before the board, three members of which, designated by the president, will question him in regard thereto. When this last part of the examination shall have ended, the board will declare the candidate either "Admitted" or "Rejected."

The examinations, both oral and written, must be in the Spanish language, or through an interpreter. In the latter case the interpreter will be entitled to a fee of $15. The department in charge

of public instruction will issue to such person as may pass this examination a degree, in the same form as that issued to graduates of the University of Havana, but stating therein that it has been obtained by examination, on presentation of a foreign diploma. The degrees so issued shall have the same legal status as those issued to the graduates of the University of Havana.

Secretary of the Faculty of Medicine and Pharmacy in the University of Havana, Dr. Hernando, Havana, Cuba.

Delaware.—"Applicants must furnish satisfactory proof of good moral character, be more than twenty-one years of age, possess a good English education, and have a diploma conferring the degree of doctor of medicine, from some incorporated medical college; which diploma must be presented to the secretary of the medical council, or the secretary of the examining board before which the candidate is to appear for examination. Applicants who have received their degree since the passage of this act, must have pursued the study of medicine for at least four years prior to the granting of this diploma."

The examinations are written, and comprise the following subjects: Anatomy, Physiology, Hygiene, Chemistry, Surgery, Obstetrics, Practice of Medicine, Pathology, Diagnosis, Therapeutics and Materia Medica. An average of 75 per cent. is required in order to pass the examination. The fee for the examination is $10.

Reciprocity is permissible with other States having requirements practically the same as those of Delaware. At present reciprocity exists with New Jersey and Maryland.

Examinations are held at Dover, twice a year, on the third Tuesday in June, and the second Tuesday in December.

Secretary of the Medical Council, P. W. Tomlinson, M.D., Wilmington, Del.

District of Columbia.—Applicants must be of good moral character. Only those who hold the degree of doctor of medicine are admitted to examination. Those who have received such degree before June 30, 1898, must have studied medicine not less than three years, and those who have received it after that date must have studied not less than four years, before graduation. The examination is both written and oral. It includes Anatomy, Physiology, Chemistry, Bacteriology, Pathology, Materia Medica and Therapeutics, Hygiene, Histology, Practice of Medicine, Surgery, Obstetrics and Gynecology, Diseases of the Eye and Ear, Medical jurisprudence, "and such other branches as may be from time to time determined by the Board of Medical Supervisors."

"A general average of 75 per cent. will entitle the candidate to a license if in no section the percentage be less than 50; a candidate having a general average of 75 or more, and having attained less than 50 in a single section, may, upon his request, be granted an immediate reëxamination in that section. If, however, a candidate have less than 50 per cent. in more than one section, or less than 33.3 in any section, his application will be rejected, no matter what may be his general average." The fee for the examination is $10.

Examinations are held quarterly, on the second Thursday in January, April, July, and October.

Reciprocity, practically none. "The Board of Medical Supervisors of the District of Columbia will reciprocate with any State or Territory, the medical law of which grants to licentiates of the Board of Medical Supervisors of the District of Columbia rights and recognition in such State or Territory equal to the rights and recognition grantable reciprocally to the licentiates of such State or Territory."

Secretary of Board of Medical Supervisors, Dr. W. C. Woodward, Washington, D. C.

Florida.—Applicants must present a diploma from a recognized medical school, and also pass an examination in the following subjects: Anatomy, Physiology, Surgery, Gynecology, Obstetrics, Chemistry, Therapeutics. There are nine examining boards in this State, one for each of the seven judicial districts (and one each for the Homœopaths and Eclectics). Each of these seven boards has its own standard for examinations. Fortunately a certificate from any one of these boards is recognized by the other boards. The fee for the examination is $10.

Reciprocity, none.

Examinations are held twice a year.

Secretaries of the State boards: First Judicial District, Dr. Louis de M. Blocker, Pensacola, Fla. Second, Dr. J. F. Williams, Monticello, Fla. Third, Dr. J. A. Townsend, Lake City, Fla. Fourth, Dr. J. H. Durkee, Jacksonville, Fla. Fifth, Dr. G. E. Welch, Palatka, Fla. Sixth, Dr. L. A. Bize, Tampa, Fla. Seventh, Dr. R. L. Harris, Orlando, Fla.

Georgia.—All applicants must be graduates of an incorporated medical college, requiring not less than three full courses of study of six months each. Applicants must pass a satisfactory examination on Anatomy, Physiology, Chemistry, Surgery, Obstetrics, Gynecology, Practice, Materia Medica and Therapeutics, Diagnosis. An average of 75 per cent. is required. The fee for the examinations is $10; but a candidate who has failed in his examination can take any subsequent examination without paying an additional fee.

Examinations are held twice a year, the first about the time of graduation from the medical colleges of the State, the other on the second Tuesday in October.

Reciprocity, none.

Secretary of the State Board of Medical Examiners, I. H. Goss, M.D., Athens, Ga.

Hawaii.—Applicants must pass an examination before the Board of Medical Examiners. The examinations are practical and are designed to demonstrate the applicants' fitness to practise medicine, or the reverse. The questions are principally upon Practice, Surgery, Obstetrics, Gynecology, Anatomy, and Physiology; although a question or two may be asked upon Histology and Chemistry. The fee for the examination is $10.

There is no reciprocity.

Chairman of the Board of Medical Examiners, C. B. Wood, M.D., 166 Beretania Street, Honolulu, Hawaii.

Idaho.—Applicants must be of good moral character, citizens of the United States, or have declared intention of becoming such, and must be graduates of a recognized reputable medical college in good standing and must present their diploma to the board for inspection. Every applicant must be examined. "The examinations are wholly in writing, and embrace the following twelve branches or subjects, with ten questions on each subject, viz., Anatomy, Physiology, Chemistry and Toxicology, Materia Medica and Therapeutics, Diagnosis, Theory and Practice, Hygiene, Obstetrics, Gynecology, Surgery, Pathology, and Histology. A general average of 75 per cent. is required by law to entitle applicant to receive a license. "The fee for examination is $25.

Examinations are held twice a year, the first Tuesday in April and October.

Reciprocity, none.

Secretary, State Board of Medical Examiners, Dr. R. L. Nourse, Hailey, Idaho.

Illinois.—Applicants must be of good moral crhacter. All applicants must present a diploma from some medical college or institution in good standing with the Illinois State Board of Health. Applicants must, further, pass the examination of the board. At present the examination consists of the following subjects: Anatomy, Chemistry, Gynecology, Hygiene, Materia Medica and Therapeutics, Medical Jurisprudence, Obstetrics, Pathology and Bacteriology, Practice of Medicine, Physiology, Surgery. Ten questions are asked on each subject. Applicants must obtain a general average of at least 75 per cent. The fee for the examination is $10. If the applicant is successful a further fee of $5 is charged for certificate of license to practise.

Examinations are held in Chicago quarterly.

Reciprocity: "Applicants who have been examined and licensed by other State examining boards having, at the time of examination, standards not lower than those required by the State Board of Health of Illinois, will be granted certificates without examination, if the Examining Board in question will recognize the certificates issued by the Illinois Board, under the provisions of the act now in force. The Illinois State Board of Health now reciprocates—in the case of licenses issued on examination—with Maine, Michigan, Nebraska, New Jersey, Ohio, Virginia, and Wisconsin, and probably Iowa and Kentucky." (Report of Illinois State Board of Health.)

Secretary State Board of Health, Dr. J. A. Egan, Springfield, Ill.

Indian Territory.—*Cherokee Nation.*—Applicants must present a diploma from a reputable and recognized medical school, and must be examined by the Board of Examiners. (There is one board for each supreme judicial district.) The fee for the examination is $10.

Examinations are held every three months.

Choctaw Nation.—Applicants must present satisfactory evidence of good moral character from "four or more citizens of the nation of good standing, to whom the applicant is known." Applicant must, further, either present a diploma which is satisfactory to the board; or must pass a satisfactory examination before the board. The fee for the examination is $25.

Muskogee or Creek Nation.—Graduates of medicine file their diploma with the board, and if satisfactory a license is granted which entitles the applicant to practise. Fee, $5. Non-graduates must submit satisfactory proof of moral character, and pass an examination before the board. The fee for the examination is $25.

Indiana.—Every applicant must be a *bona-fide* resident of the county and State. Applicants must be graduates of a medical college recognized as in good standing. An examination is required of all applicants, with the following exception: "The only applicants exempt from examination are the graduates of reputable medical colleges located in Indiana, who matriculated therein prior to January 1, 1901, and graduated therefrom, and make application for registration prior to January 1, 1905." Fee, $10.

After January 1, 1905, an examination will be required of all candidates. The subjects for examination are Anatomy, Physiology, Obstetrics, Gynecology, Materia Medica, and Therapeutics, Theory and Practice of Medicine, Chemistry, Surgery, Pathology, Bacteriology, Hygiene, Histology, Rhinology, Medical Jurisprudence, Ophthalmology, Otology, Laryngology, and Dermatology. The examination begins the second Tuesday in January and July. Applications for examination, accompanied by diploma and fee, $25, should be on file in the office of the board at least five days prior to the date of examination. To pass the examination a candidate must obtain a total average of 75 per cent. A candidate having less than 50 per cent. in one subject shall be rejected; but he is entitled to a second examination within a year without paying another fee.

Reciprocity: "Indiana is willing to reciprocate with all sister States on the following conditions, viz., 1. That the applicant for reciprocal recognition must present, or give satisfactory evidence of possessing a diploma from a medical institution that is recognized, at the time for application, by the Indiana Board of Medical Registration and Examination. 2. Acceptable proof must be furnished that the applicant has been examined by a legally constituted State board authorized to examine applicants to practise medicine and surgery." Reciprocity now exists with Michigan, Nebraska, and Wisconsin.

The Secretary of the Board of Medical Registration and Examination is W. T. Gott, M.D., Crawfordville, Ind.

Iowa.—Applicants must be of good moral character. "After January 1, 1899, no person can begin the practice of medicine in Iowa excepting upon examination; and no person will be admitted to examination except upon graduation from a medical college recognized by the board as of good standing; and no college will be so recognized by the board that does not require of those graduating after January 1, 1899, attendance upon four full courses of study of not less than twenty-six weeks each, no two of which courses shall have been taken within one year, as a condition of such graduation. The examinations are practical in character, and embrace Anatomy, Chemistry, Materia Medica and Therapeutics, Obstetrics, Pathology, Physiology, Practice, and Surgery. Ten questions are asked upon each branch, the answers to which must be written. The board requires a general average of 75 per cent. on a scale of 100. In case of failure, and reëxamination, no credit is given for percentages gained in a former examination, but the reëxamination must, as in the former one, be upon all branches." The fee for the examination is $10; in case of failure a reëxamination can be taken without payment of additional fee.

Examinations are held two weeks before the first Tuesday in February, May, August, and November.

Reciprocity has been provided for by a recent amendment to the medical law, but is not yet in operation.

Secretary of the State Board of Medical Examiners, Dr. J. F. Kennedy, Des Moines, Iowa.

Kansas.—Applicants must be of good moral character. "The basis of all registration for the practice of medicine and surgery will be a satisfactory examination by the board. All applicants must have one of the following qualifications to be admitted to the examination: (1) They must have attended a legally qualified medical school two years and have had ten years' practice, or (2) They must have attended a legally qualified medical school three years and have had five years' practice, or (3) They must have attended a legally qualified medical school four years. The board shall be the judge of what constitutes a legally qualified medical school."

The examination will be on the following subjects: Anatomy and Histology, Chemistry, Obstetrics and Gynecology, Materia Medica and Therapeutics,

Pathology, Bacteriology, Theory and Practice of Medicine, Physiology, Surgery. The fee for examinations is $15.

Examinations are held at Topeka on the second Thursday in February, June, and October.

Reciprocity, none.

Secretary of the State Board of Medical Registration and Examination, O. F. Lewis, M.D., Hepler, Kan.

Kentucky.—Applicants may receive a certificate from the Board of Health, enabling them to practise in the State, on presenting evidence of any of the following qualifications: (1) A diploma from a reputable medical college legally chartered under the laws of the State. (2) A diploma from a reputable and legally chartered medical college of some other State or country, endorsed as such by the State Board of Health. (3) Satisfactory evidence from the person claiming the same that such person was reputably and honorably engaged in the practice of medicine in the State prior to February 23, 1864. (4) Satisfactory evidence from any person who was reputably and honorably engaged in the practice of medicine in the State prior to February 23, 1884, who has passed a satisfactory practical examination before said board."

Fee for certificate, $2, and for recording, 50 cents. Non-residents of the State are not allowed to register. Reciprocity: The Board may, acting under its general powers, reciprocate with other States in which the standards are no lower than in Kentucky.

Secretary of the State Board of Health, Dr. J. N. McCormack, Bowling Green, Ky.

Louisiana.—Applicants must be twenty-one years of age, of good moral character, and possess at least a fair primary education. Applicants must also present to the Board of Medical Examiners a diploma from a medical college in good standing; such standing to be determined by the board. A satisfactory examination must be passed in Anatomy, Physiology, Chemistry, Principles of Medicine, Obstetrics, Physical Diagnosis, Surgery, Materia Medica, Hygiene. The fee for the examination is $10; in case of failure $5 only is retained. Examinations are held twice a year in New Orleans.

Reciprocity, none.

Secretary of the State Board of Medical Examiners, F. A. Larue, M.D., 624 Gravier Street, New Orleans, La.

Maine.—Applicants must be of good moral character. It is necessary to have a diploma from some reputable medical school or college, maintaining a standard of preliminary education and of medical instruction acceptable to the board. The standard of medical instruction which the board will approve is three years of medical study and three courses of lectures for those who graduated previous to 1902, and four years' study and four courses of lectures after 1901. Five years of reputable practice before 1901 will be accepted in lieu of one year's study. It is further necessary to pass an examination in Anatomy (including Histology), Physiology, Pathology (including Bacteriology), Materia Medica and Therapeutics, Practice, Surgery (including diseases of the eye and ear), Obstetrics (including Gynecology), the above in writing, ten questions on each paper; also a brief oral examination in hygiene, chemistry, medical jurisprudence, etc. A rating of an average of 75 per cent is required. Fee, $10 for examination, and $2 for certificate. Examinations are held in March, July, and November.

Reciprocity: "The Maine Board will register any person who is eligible to examination by our board and who has been examined and received a rating of at least 75 per cent. by any board that maintains a standard equal to our own and been registered by it, provided the board will accept our certificate under similar circumstances." Reciprocity now exists with Illinois, Michigan, New Jersey, and probably Ohio.

Secretary of the Board of Registration of Medicine, A. K. P. Meserve, M.D., 109 Emery Street, Portland, Me.

Maryland.—Applicants must be of good moral character, must submit evidence of a competent common-school education, and must have received a diploma from a medical school in the United States, requiring a four years' course, and recognized by the American Medical College Association or the Intercollegiate Committee of the American Institute of Homœopathy. Medical students at the end of their second year of study who have, as verified by the certificate of the dean of the college which they have attended, completed the studies of Anatomy, Physiology, Medical Chemistry, and Materia Medica in said college may be examined in these subjects. All applicants must pass an examination in Anatomy, Physiology, Medical Chemistry, Surgery, Practice of Medicine, Materia Medica, Therapeutics, Obstetrics, and Pathology. Fee, for the examination is $15. In case of failure the fee is not returnable, but the applicant is allowed a reëxamination without further fee.

Reciprocity: "The board is authorized to recognize certificates issued by other States whose requirements are of as high a standard as those of Maryland, provided such other State will, in a similar manner, recognize the certificates issued by the board of Maryland." Reciprocity exists at present with Delaware and New Jersey.

Secretary of the Board of Medical Examiners, Dr. J. McP. Scott, Hagerstown, Md.

Massachusetts.—Applicants must furnish proof of being twenty-one years of age or over, and of good moral character. A medical diploma is not necessary, and non-graduates in medicine are admitted to the examination. Examination is compulsory for all applicants. "Examinations shall be wholly or in part in writing in the English language, and shall be of a scientific and practical character. They shall include the subjects of Anatomy, Surgery, Physiology, Pathology, Obstetrics, Gynecology, Practice of Medicine and Hygiene, and shall be sufficiently thorough to test the applicant's fitness to practise medicine. When the general average of the ratings given the several sets of papers of an applicant by the individual examiners is below 70 per cent. his examination is regarded unsatisfactory. If, however, one's general average is found to be near the minimum requirement, his papers are reviewed by the board in general session, and his ratings fixed by a consensus of opinion." A person refused registration by reason of failure to pass a satisfactory examination is entitled to two reëxaminations within one year after his first failure, without filing a new application or paying an additional fee. The fee for the examination is $20.

Examinations are held on the second Tuesday and Wednesday of March, July, and November. Special examinations are also held at same time in May and September.

There is no reciprocity.

Secretary of Board of Registration, Edwin B. Harvey, M.D., State House, Boston, Mass.

Michigan.—Applicants must furnish proof of being over twenty-one years of age, and of good moral character. Each applicant must also have received previous to the beginning of his course in medicine, a diploma from a recognized and reputable

high school, academy, college, or university, having a classical course, or shall pass an examination equivalent at least to the minimum standard of preliminary education adopted by the board. Each applicant must also have received a medical diploma from a reputable college of medicine within the United States, or within any foreign nation (provided such foreign nation accord a like privilege to graduates of approved medical colleges of this State), having at least four years' course of seven months each calendar year, as shall be approved and designated by the Board of Registration in Medicine. *Exemption:* "The requirement of medical education shall not apply to those graduates of legally organized and reputable medical colleges approved by said board who had graduated from such college previous to the date of the passage of this act (September 16, 1903); and students complying with the other provisions of this section, who, on January 1, 1903, were regularly registered as students of legally organized and reputable medical colleges of this State, approved by said board, may obtain a certificate of registration as graduates of such colleges and without examination by the board upon payment of a fee of $10."

Applicants must satisfactorily pass an examination on Anatomy, Physiology, Chemistry, Pathology, Materia Medica and Therapeutics, Toxicology, Histology, Practice of Medicine, Surgery, Obstetrics, Gynecology, Mental and Nervous Diseases, Diseases of the Eye, Ear, Nose, and Throat, Bacteriology, Hygiene, Public Health Laws of Michigan, and Medical Jurisprudence. An average of at least 75 per cent. is required. The fee for examination is $25, except that graduates of any medical school in the State of Michigan, approved by the board, shall only pay a fee of $10.

Examinations are held at Lansing on the second Tuesday of June and October.

At present reciprocity exists with Illinois, Indiana, Iowa, Kentucky, Maine, Maryland, Nebraska, New Jersey, Ohio, Wisconsin.

Secretary of the State Board of Registration, B. D. Harison, M.D., Sault Ste. Marie, Mich.

Minnesota.—Each applicant is required to give satisfactory proof of age, place of residence, time and place of each course of lectures, and date of graduation. Graduates of medical colleges granting advanced standing for work done at other than medical colleges shall not be eligible to the examinations given by this board. Each applicant, if he graduated or completed his final course of lectures after January 1, 1899, must show proof that he has attended four full courses of lectures at a recognized medical college, no two courses being in the same year. Each applicant, if he graduated after July 1, 1887, and prior to January 1, 1899, or completed his final course of lectures during that period, must show proof that he has attended three full courses of lectures at a recognized medical college, no two courses being in the same year. Applicants who graduated at a recognized medical college prior to July 1, 1887, must show proof of having attended two courses of lectures at a medical college. An examination is required of each and every one on Anatomy, Physiology, Chemistry, Histology, Materia Medica, Therapeutics, Preventive Medicine, Practice of Medicine, Surgery, Obstetrics, Diseases of Women and Children, Diseases of the Nervous System, Diseases of the Eye and Ear, Medical Jurisprudence, and such other branches as the board shall deem advisable. Ten questions are given on each paper. A general average of 75 per cent. must be attained. "Handwriting of candidates must be legible, and orthography must not be such as will disgrace the medical profession." Fee for the examination is $10. This fee is not returned in case of failure.

Examinations are held at Minneapolis, on the first Tuesday of January, April, June, and October.

Reciprocity, none.

Secretary of the State Board of Medical Examiners, C. J. Ringnell, M.D., 512 Nicollet Avenue, Minneapolis, Minn.

Mississippi.—"The application for license must state: (1) The applicant's name in full; (2) his place of residence and post-office address; (3) his nativity and age; (4) the time spent by him in medical studies; (5) the name and post-office address of the preceptor under whom medical studies were pursued; (6) courses of medical lectures attended; (7) name of medical school attended; (8) if a graduate of a medical college, name thereof; (9) time spent in hospital; (10) time spent in the practice of medicine, if any; (11) school or system of practice chosen, and (12) references as to his personal character." Everyone must be examined. Examinations are in Anatomy, Chemistry, Obstetrics, Materia Medica, Physiology, Pathology, Surgery, and Hygiene. The fee for the examination is $10.25.

Examinations are held at Jackson, twice a yea on the second Tuesday in May and October.

Reciprocity, none.

Secretary of the State Board of Health, Dr. J. F. Hunter, Jackson, Miss.

Missouri.—Applicants must furnish evidence of preliminary education and of good moral character. Any student who matriculated in any medical college of the State of Missouri on or prior to March 12, 1901, subsequently graduating from a medical college in the State, may receive from the Board of Health a license to practise medicine without undergoing examination, provided that said student pays to the Board of Health a fee of $15, and presents a diploma from any medical college in the State. This became effective on June 24, 1903. All other applicants must take an examination in the following subjects: Anatomy, Chemistry, Physiology, Pathology, Therapeutics, Obstetrics, Gynecology, Surgery, Practice of Medicine, Medical Jurisprudence, Hygiene, and Bacteriology. In order to pass, an average of 75 per cent. is required. The fee for examination is $15, which entitles the applicant, in case of failure, to reëxamination within one year without paying an additional fee.

Examinations are held quarterly.

Reciprocity, none.

Secretary of the State Board of Health is Dr. W. F. Morrow, Kansas City, Mo.

Montana.—Every applicant who graduated after June 30, 1898, must present evidence of having attended four courses of lectures of at least six months each. Applicants must present a diploma from a legally organized medical school in good standing, and also pass an examination in the following subjects: Anatomy, Physiology, Materia Medica, Therapeutics, Practice of Medicine, Surgery, Obstetrics, Diseases of Women and Children, Diseases of the Nervous System, Diseases of the Eye and Ear. "Such examinations shall be both scientific and practical, but of sufficient thoroughness to test the candidates' fitness to practise medicine and surgery." A general average of 75 per cent. is required in order to pass the examination. The fee for the examination is $15.

Examinations are held in Helena on the first Tuesday of April and October, and at such other times and at the same and other places as the board may determine.

Reciprocity, none.

Secretary of the Board of Medical Examiners is Dr. W. C. Riddell, Helena, Mont.

Nebraska.—Applicants must be of good moral character. The applicant must furnish proof that he is a graduate of a medical school or college in good standing, requiring a four years' course. (No medical school will be recognized by the board, unless said school is recognized by the Association of Medical Colleges of the School of Practice to which it belongs.) Applicants must further pass examination by the board. "The examination shall embrace those subjects and topics, a knowledge of which is commonly and generally required of candidates for the degree of Doctor of Medicine, by reputable medical colleges in the United States." At a recent examination the subjects were: Anatomy, Chemistry, Physiology, Pathology, Practice, Surgery, Obstetrics, Gynecology, Materia Medica. "Every holder of a diploma from a recognized medical college within the State of Nebraska, making application for an examination and certificate under the provisions of this act, shall pay to the Board of Secretaries prior to his examination the sum of $10. All other persons, making such application shall pay to said board the sum of $25."

Reciprocity: The State Board of Health may at its discretion admit, without examination, legally qualified medical practitioners who hold certificates to practise medicine in any State with equal requirements to those of the State of Nebraska.

Reciprocity now exists with Illinois, Indiana, Michigan, and Wisconsin, and probably will soon be established with Iowa.

Secretary of the State Board of Health, Dr. Geo. H. Brash, Beatrice, Neb.

Nevada.—Applicants must be of good moral character. "Certificates of license to practise are issued, without examination, to all who furnish satisfactory proof of having received diplomas or licenses from reputable and legally chartered medical institutions of the United States which are in good standing, or from the State examining board of any State of the United States, providing the holder of said State certificate has been practising in this State for at least five years. The board shall also issue a certificate to any person who shall have been regularly engaged in the practice of medicine and surgery within this State for five years immediately preceding the passage of this act, and who, after an examination by said board, shall be found to be qualified to practise medicine and surgery. It shall also issue a certificate to any person who has had issued to him a diploma or license from any reputable school or college of medicine and surgery which is located without the United States, upon the applicant being found competent after having passed a satisfactory examination by the said board. All examinations of applicants to practise shall be thorough and searching, and shall be in the following branches: Anatomy, Physiology, Chemistry, Materia Medica, Therapeutics, Principles and Practice of Medicine, Principles and Practice of Surgery, Gynecology, Obstetrics, Ophthalmology, Pathology, and all subjects relating to the practice of medicine and surgery." Fee for certificate is $25.

Examinations are held on the first Monday of May and November.

Secretary of the State Board of Medical Examiners is Dr. S. L. Lee, Carson City, Nev.

New Hampshire.—"The regent shall admit to examination any candidate who pays a fee of $10 and submits satisfactory evidence, verified by oath, if required, that he—(1) Is more than twenty-one years of age; (2) Is of good moral character; (3) Has graduated from a registered college; or satisfactorily completed a full course in a registered academy or high school; or had a preliminary education considered and accepted by the regent as fully equivalent; (4) Has studied medicine not less than four full school years, of at least nine months each, including four satisfactory courses, of at least six months each, in four different calendar years, in a medical college registered as maintaining at the time a satisfactory standard; the regent shall accept, as the equivalent for any part of the third and fourth requirements, evidence of five or more years' reputable practice, provided that such substitution be specified in the license; (5) Has either received the degree of bachelor or doctor of medicine from some registered medical school, or a diploma or license conferring full right to practise medicine in some foreign country."

"No licenses issued by States, or diplomas from medical colleges, are endorsed by the regent in place of examination with one exception, graduates from Dartmouth Medical School may receive a certificate on presentation of diploma, if said diploma shall have been issued between the enactment of the Medical Law, March, 1897, and January 1, 1903."

Examinations are held at Concord, at least twice a year. The subjects for examination are: Anatomy, Physiology and Hygiene. Chemistry. Surgery, Obstetrics, Pathology and Diagnosis, and Therapeutics (including Practice and Materia Medica). The fee for the examination is $10.

Reciprocity, none.

Regent of the State Board, Channing Folsom, Concord, N. H.

New Jersey.—Applicants must be over twenty-one years of age, and of good moral character. They must give proof of having received a satisfactory academic education, or must pass an examination before the State or County Board of Examiners for Teachers, application for which must be made to the State Superintendent of Public Instruction, Trenton, N. J., at least ten days before the examination.

Candidates must have received a diploma from some approved medical college, and have also studied medicine not less than four full school years of at least nine months each, in some legally incorporated American or foreign medical college or colleges, prior to the granting of said diploma. Candidates who graduated prior to July 4, 1903, however, and have been in continuous and reputable practice for at least five years since graduation may be admitted to the examinations upon satisfactory evidence of three courses of medical lectures in different calendar years. Candidates who graduated prior to July 4, 1894, and have been in continuous and reputable practice since graduation may be admitted to examination upon satisfactory evidence of two courses of medical lectures in different calendar years.

Examinations are held in Materia Medica and Therapeutics; Obstetrics and Gynecology; Practice of Medicine, including Diseases of the Skin, Nose, and Throat; Surgery, including Surgical Anatomy and Diseases of the Eye, Ear, and Genitourinary Organs; Anatomy; Physiology; Chemistry; Histology, Pathology, and Bacteriology; Hygiene and Medical Jurisprudence. In each of these sections fifteen questions are submitted, of which ten must be answered by the candidate. A total average of 75 per cent. shall be necessary to license, provided that in no section shall the average be less than 50 per cent. The fee for the examination is $25.

Examinations are held at Trenton on the third Tuesday in June and October.

Reciprocity: New Jersey reciprocates with Dela-

vare, Maine, Maryland, Illinois, Virginia, and Washington; and endorses the licenses issued by New York and Pennsylvania.

Secretary of the State Board of Medical Examiners, E. L. B. Godfrey, M.D., Camden, N. J.

New Mexico.—"Each applicant must furnish, s references regarding moral character and professional standing, two or more names of reputable physicians, preferably the president and secretary f State Licensing Board, or president and secretary f State Medical Society where applicant last reided. Non-residents of the Territory of New lexico will not be licensed under any condition. ll applicants presenting foreign diplomas must ass supplementary examinations, besides comlying with other requirements demanding good oral character and professional standing, as well s evidence of preliminary education." Diplomas rom a recognized medical school requiring a four ears' course entitles to a license; all other applicants must pass the examination.

The examination is written and oral and consists of: 1) Practice of Medicine, Pathology and Bacteriology; (2) General Surgery, including Surgical Pathology and Surgical Bacteriology; (3) Obstetrics, Gynecology, Embryology; (4) Toxicology; (5) Inorganic and Medical Chemistry; (6) Physiology; 7) Anatomy. A minimum average of 65 per cent. s required and must not fall below 45 per cent. in nore than one subject. The fee for the examinaion is $25. The fee for license on presentation of liploma is $15.

Examinations are held twice a year at Santa Fe on irst Monday of June and December.

Reciprocity, none.

Secretary of the Board of Health, D. B. Black, M.D., Las Vegas, N. M.

New York.—Candidates have to submit satisactory evidences, verified by oath, if required, as ollows: (1) Evidence that applicant is more than wenty-one years of age. (2) Certificates of moral haracter from not less than two physicians in good standing. (3) Evidence that applicant has he general education required, preliminary to reeiving the degree of bachelor or doctor of medicine n this State. (4) Evidence that applicant has tudied medicine not less than four full school ears of at least nine months each, including four atisfactory courses of at least six months each, in our different calendar years in a medical school egistered as maintaining at the same time a atisfactory standard. The increase in the required ourse of medical study from three to four years did not take effect until January 1, 1898, and does not apply to students who matriculated before that date and receive the degree of M.D. before January 1, 1902. The regents may, in their discretion, accept as the equivalent for any part of the third and fourth requirement, evidence of five or more years reputable practice, provided that such substitution be specified in the license; and as the equivalent of the first year of the fourth requirement evidence of graduation from a registered college course, provided that such college course shall have included not less than the minimum requirements prescribed by the regents for such admission. (5) Evidence that applicant has either received the degree of bachelor or doctor of medicine from some registered medical school, or has a diploma or license conferring full right to practise medicine in some foreign country,

Applicants must also pass an examination in (1) Anatomy; (2) Physiology and Hygiene; (3) Chemistry; (4) Surgery; (5) Obstetrics; (6) Pathology and Diagnosis; (7) Therapeutics, Practice and Materia Medica. Each paper has fifteen questions, and of these the applicant selects ten. The fee for the examination is $25. Candidates must obtain 75 per cent. on each paper. All subjects must be passed at the same examination, except that a candidate who has been rejected in but one paper, and whose total average is at least 80 per cent., is reëxamined again in the subject in which he failed.

Examinations are held at New York, Albany, Syracuse, and Buffalo, in January, May, June, and September.

Reciprocity, none.

Secretary of the Regents of the University of New York, _____, Jr., Albany, N. Y.

North Carolina.—Applicants must present a certificate of good moral character from two persons known to the board. "All applicants shall exhibit a diploma, or furnish satisfactory proof of graduation from a medical college in good standing requiring an attendance of not less than three years and supplying such facilities for clinical instruction as shall meet the approval of the board. But license or other satisfactory evidence of standing as a legal practitioner in another State shall be accepted in lieu of a diploma and entitle to examination." Applicants must, further, be examined in the following subjects: Surgery, Anatomy and Histology, Materia Medica and Therapeutics, Practice of Medicine, Obstetrics, Gynecology and Pediatrics, Physiology and Hygiene, Chemistry and Pharmacy. To secure a license an average grade of not less than 80 per cent. will be required, but an applicant receiving a grade of 35 per cent. or less in any one branch shall be rejected regardless of his grade in other branches. The fee for the examination is $10, which shall be returned in the event of the applicant's rejection.

Reciprocity, none.

Secretary of the Board of Medical Examiners is Dr. Geo. W. Pressly, Charlotte, N. C.

North Dakota.—Applicants must present evidence of having attended three courses of lectures of at least six months each. "Applicants must further pass an examination in the following branches: Anatomy, Physiology, Chemistry, Histology, Materia Medica, Therapeutics, Diseases of Women and Children, Diseases of the Nervous System, Diseases of the Eye and Ear, Medical Jurisprudence, and such other branches as the board deems advisable. The board shall cause such examination to be practical and scientific and sufficient to test the candidate's fitness to practise medicine, surgery, and obstetrics." Seventy-five per cent. is required to pass. The fee for the examination is $20.

Examinations are held at Grand Forks, the first Tuesday in January, April, July, and October.

Reciprocity, none.

Secretary of the State Board of Medical Examiners, H. M. Wheeler, M.D., Grand Forks, N. D.

Ohio.—Applicants must furnish satisfactory proof of being more than twenty-one years of age and of good moral character. They must also give evidence of preliminary education practically equivalent to that necessary for admission to a reputable college granting the degree of A.B., B.S., or equivalent degree. Applicants must further show that they are graduates in medicine from some college recognized by the State Board of Medical Registration and Examination. Applicants will then have to pass an examination in the following subjects: Anatomy, Physiology, Pathology, Chemistry, Materia Medica and Therapeutics, the Principles and Practice of

Medicine, Obstetrics, Diseases of Women and Children, and Physical Diagnosis. The fee for the examination is $25.

Examinations are held at Cleveland, Columbus, and Cincinnati on the second Tuesday of June and December.

Reciprocity upon examination certificates, with Illinois, Indiana, Michigan, and Wisconsin.

Secretary of the State Board of Medical Registration and Examination, Frank Winders, M.D., Columbus, Ohio.

Oklahoma.—Applicants must submit proof of good moral character. Applicants must also submit proof of graduation from a reputable medical college, or proof of ten years' continuous practice. Applicants must further pass an examination in the following subjects: Anatomy, Physiology, Chemistry, Materia Medica and Therapeutics, Medical Jurisprudence, Surgery, Obstetrics, Physical Diagnosis, Practice.

A grade of 66⅔ per cent. must be attained in each branch. The fee for examination is $5.

Examinations are held every three months. Notice will be given of time and place.

Reciprocity, none.

Secretary of Board of Health, Dr. E. E. Cowdrick, Enid, Oklahoma.

Oregon.—Applicants must be "of good repute," must make application stating time spent in study of medicine, place of study, and time and place of actual practice. Applicants must also pass an examination in the following branches: Anatomy, Physiology, Chemistry, Materia Medica, Therapeutics, Practice of Medicine, Surgery, Obstetrics, Diseases of Women, Medical Jurisprudence, and such other branches as the board shall deem advisable. Such examination shall be both scientific and practical, and of sufficient severity to test the candidate's fitness to practice medicine and surgery, and shall be written or printed (or partly written or partly printed), questions and answers. The fee for the examination is $10.

Examinations are held at Portland, Oregon, on the first Tuesday of January and July.

Reciprocity is permitted, but has not yet been arranged for.

Secretary of Board of Medical Examiners, Byron E. Miller, M.D., Portland, Oregon.

Pennsylvania.—Applicants must present satisfactory evidence of being more than twenty-one years of age, and of good moral character. Applicants must show that they have received sufficient preliminary education for admission to the freshman class in a literary college, otherwise they will have to pass a preliminary examination in Arithmetic, Grammar, Geography, Orthography, American History, and English Composition. Applicants must also have received a diploma conferring a degree in medicine from a legally incorporated medical college of the United States, or a diploma or license conferring the full right to practise all the branches of medicine and surgery in some foreign country. "Applicants who received their degree in medicine after the 1st day of July, 1894, must have pursued the study of medicine for at least three years, including three regular courses of lectures in different years, in a legally incorporated medical college or colleges, prior to granting of the said diploma, or foreign license, and after the 1st day of July, 1895, such applicants must have pursued the study of medicine for at least four years, including three regular courses of lectures, in different years, in some legally incorporated medical college, or colleges, prior to the granting of said diploma or foreign license." Applicants must also pass an examination in Anatomy, Physiology, Hygiene, Chemistry, Surgery, Obstetrics, Pathology, Diagnosis, Therapeutics, Practice of Medicine, and Materia Medica. A general average of not less than 75 points is necessary. No license shall be issued to any candidate whose examination papers shall, on any two subjects, fall below fifty-five; provided, that those papers marked below fifty-five shall be subject to revision by the entire board by which the candidate was examined. The fee for the examination is $25.

Examinations are held twice a year—in June and December.

Reciprocity is allowed by law, and formerly certificates from New Jersey and New York were endorsed; but first the New Jersey licenses were refused, and now (since February, 1904) the New York licenses are not recognized, the Medical Council of Pennsylvania finding "on careful examination that the standard of acquirements of the medical examination of the State of New York is not substantially the same as that of the medical examination of the State of Pennsylvania."

Secretary of the State Board of Medical Examiners, Hiram S. McConnel, M.D., New Brighton, Pennsylvania.

Philippines.—"In accordance with the provisions of an Act Regulating the Practice of Medicine and Surgery in the Philippine Islands enacted December 4, 1901, it shall be unlawful after March 1, 1902, for any person to practise medicine in any of its branches in the Philippine Islands unless he holds a certificate of registration from the Board of Medical Examiners for the Philippine Islands. Such certificates are granted without examination to persons engaged in the practice of medicine in the Philippine Islands prior to the passage of this act who submit to the Board of Medical Examiners a diploma of Doctor of Medicine from a reputable medical school or college, to certain students in the St. Thomas University in the City of Manila and to persons who have passed the examinations before a board of examiners convened pursuant to special order No. 5 and Circular No. 6 of the United States Military Government of the Philippine Islands, dated respectively February 25 and April 1, 1900. Every other person desiring to begin the practice of medicine and surgery in the Philippine Islands must apply to the Board of Medical Examiners for a certificate of registration as Doctor of Medicine, and submit to an examination in the usual branches of medicine, and also present a diploma of Doctor of Medicine from a medical school or college recognized as reputable by the Board of Health of the Philippine Islands. The Board of Medical Examiners meets in the city of Manila for the purpose of examining candidates on the second Tuesday in January, April, July, and October of each year. Applications for examination should be made to the Secretary-Treasurer of the Board of Medical Examiners of the Philippine Islands, Manila." (From the Report of the Illinois State Board of Health, for 1903.)

Porto Rico.—Each applicant must furnish proof that he "is a graduate of a medical school or institution in good standing and legally organized, and duly approved by said board of examiners. If the diploma is found genuine, which fact the said board of examiners shall determine, and if the person presenting and claiming said diploma be the person to whom the same was originally granted, at a time and place designated by said board, or at a regular

meeting of said board, said applicant shall be required to take an examination embracing those general subjects and topics, a knowledge of which is commonly and generally required of candidates for the degree of doctor of medicine by respectable medical colleges in the United States." "The standard for examination is that for the New York State regents, and a study of their reports will give an idea of the nature of the examination here" (Secretary of Superior Board of Health, February 1, 1904). "Applicants who possess diplomas from reputable medical colleges, and who have been licensed by State boards, may, upon the payment of a fee of twenty-five dollars ($25), be licensed by the board of examiners without examination if the board of examiners so decides." The fee for the examination is $10; and $5 for a certificate if issued. In case of failure to pass the examination, the applicant shall be entitled to a second examination within six months without fee.

Examinations are held on the first Tuesday of April and October at San Juan.

Secretary of the Board of Medical Examiners, Dr. Quevedo Baez, San Juan, Porto Rico.

Rhode Island.—Applicants must be reputable physicians and must pass an examination as follows: "Examinations shall be in writing and in English, and of a practical character, but sufficiently strict to test the qualifications of the applicant as a practitioner. Examinations will be presented upon the following subjects or groups of subjects: (1) Anatomy and Physiology; (2) Materia Medica and Chemistry; (3) Pathology; (4) Surgery; (5) Theory and Practice; (6) Obstetrics and Gynecology; (7) Hygiene and Medical Jurisprudence. Ten questions will be presented upon each subject or group of subjects. An average of 75 per cent. of correct answers will be required." The fee for the examination is $10, and for the certificate (if issued) $2.

Examinations are held in Providence, on the first Thursday in January, April, July, and October.

Reciprocity, none.

Secretary of the State Board of Health, Dr. Gardner T. Swarts, M.D., Providence, Rhode Island.

South Carolina.—Applicants must exhibit a diploma from a recognized medical college, a certificate of moral character, and must pass a satisfactory written examination on all the branches of medicine. But one examination for permanent license is held each year. The President and Secretary of the Board are allowed to grant a temporary license to practice medicine until the meeting of the Board in May of each year, at which time the applicant must come up for the regular written examination above mentioned. The applicant for a temporary license will be expected to stand an oral examination on all the branches of medicine. A fee of $2.50 is charged for temporary license.

Examinations are held under the following heads: (1) Anatomy, General and Regional; (2) Physiology, Histology and Hygiene; (3) Chemistry, Practical Urinalysis, Medical Physics; (4) Materia Medica and Therapeutics and Toxicology; (5) Surgery and Surgical Pathology; (6) Practice and Diseases of Children; (7) Obstetrics and Gynecology. An average of at least 75 per cent. on the whole list of subjects shall be attained by each applicant, and he shall not make less than 60 per cent. on any one branch. A fee of $5 will be required of each applicant. This fee will be refunded to those failing to pass.

Examinations are held once a year at Columbia, on the third Tuesday in May.

Reciprocity with other States having equal requirements is permitted by law.

Secretary of State Board of Medical Examiners, C. S. Baker, M.D., Sumter, South Carolina.

South Dakota.—Applicants must give satisfactory proofs of being at least twenty-one years of age, and of good moral character. "Applicants must also present evidence of having attended four full courses of lectures, of at least twenty-six weeks each in a legally organized and reputable medical college, recognized by the Board of Medical Examiners, no two courses being in the same year; and of having received a diploma from a legally organized and reputable medical college, which shall be in good standing as shall be determined by the board, and said diploma must be submitted to the board for inspection and verification; provided that the four courses of lectures of six months each shall not apply to applicants who graduated prior to 1898. Applicants must also pass an examination in the following subjects: Anatomy, Physiology, Chemistry, Pathology, Therapeutics, Practice of Medicine, Surgery, Obstetrics, Gynecology, Diseases of the Eye and Ear, Bacteriology, Medical Jurisprudence, and such other branches as the board may deem advisable." An average of at least 75 per cent. is required in order to pass the examination. The fee for the examination is $20.

Examinations are held twice a year, on the second Wednesday of January and July, at places determined by the board.

Reciprocity, none.

Secretary of Board of Medical Examiners, H. E. McNutt, M.D., Aberdeen, South Dakota.

Tennessee.—Applicants must be of good moral character. Every applicant must take the medical examination. "In examining the written answers of the applicants (in the medical examination), the evidences of an English education as shown in the papers shall be considered in determining the fitness of an applicant for license to practise medicine in this State." Examinations shall be both written and oral, and upon the following branches: Anatomy, Physiology, Chemistry, Pathology, Surgery, Obstetrics, Materia Medica, and Practice. Candidates must obtain 75 per cent. in order to pass. The fee for the examination is $10.

Examinations are held once or twice a year in Nashville.

Secretary of the State Board of Medical Examiners, T. J. Happel, M.D., Trenton, Tenn.

Texas.—Applicants must submit satisfactory evidence of being more than twenty-one years of age, and of good moral character. "The applicant shall be examined in the following branches: Anatomy, Physiology, Chemistry, Materia Medica, Therapeutics, Histology, Pathology, Practice of Medicine, Surgery, including Diseases of the Eye, Ear, Nose, and Throat, Obstetrics, Gynecology, Hygiene, and Medical Jurisprudence. A general average of not less than seventy-five of a possible one hundred points, if in no section the percentage be less than fifty, shall entitle the applicant to practise medicine and surgery in the State of Texas, provided that he or she has otherwise complied with the law. An applicant having a general average of seventy-five or more, and having attained less than fifty in a single section, may, upon his or her request, be granted an immediate reëxamination in that section. If, however, an applicant has less than fifty in more than one section, or less than 33⅓ per cent. in any one section, his or her application will be rejected, no matter what may be his or her general average." In case of rejection no reëxamination shall be taken within a year. The fee for examination is $15.

Examinations are held at least twice a year.

Reciprocity: Licenses will be accepted from

States having requirements equal to those of Texas. "States from which license may be accepted from applicants without examination by the Board of Medical Examiners for the State of Texas: Delaware, District of Columbia, Georgia, Iowa, Louisiana, Maryland, Mississippi (if issued since July 1, 1901), Montana, Nevada, New Hampshire, New Jersey, New York, North Carolina, Oregon, Pennsylvania, South Carolina, Utah, Virginia, Washington (State of)."

Secretary of the Board of Medical Examiners, Dr. M. M. Smith, Austin, Tex.

Utah.—Applicants must have received a degree or diploma from a chartered medical college, in good standing, and must also pass an examination. The subjects for examination are: Bacteriology, Histology, Medical Jurisprudence, Practice and Pathology, Pediatrics, Chemistry, Materia Medica, Therapeutics, Obstetrics and Gynecology, Diseases of Skin, Anatomy, Surgery, Eye, Ear, Nose and Throat, Hygiene, Physiology. An average of 75 per cent. is required. The fee for the examination is $15.

Examinations are held at Salt Lake City on the first Monday in January, April, July, and October.

Reciprocity, none.

Secretary of the Board of Medical Examiners, R. W. Fisher, M.D., Salt Lake City, Utah.

Vermont.—Applicants must present a diploma from a medical college or university, and also pass an examination. All applicants will be examined on the following subjects: Anatomy, Physiology, Chemistry, Materia Medica and Therapeutics, Practice of Medicine, Surgery, Pathology, Obstetrics, Hygiene. "In order to receive consideration, examination papers must be legibly written in English and free from such errors in spelling, grammar, and reasoning as would show gross ignorance of the elementary branches of education." Graduates of Canadian medical colleges are required to attend at least one course of lectures and pass the final examinations of some legally recognized medical college in the United States.

The fee for the examination is $5.

Examinations are held at Burlington, on the second Wednesdays of January, April, and July, and the first Wednesday of October.

Reciprocity is permitted with other States whose requirements are equivalent to those of Vermont, and who will also reciprocate with Vermont.

Secretary of the State Board of Medical Censors, S. W. Hammond, M.D., Rutland, Vermont.

Virginia.—Applicants must present their diplomas from some medical college, chartered by the State or Territory in which it is situated. The Medical Examining Board of Virginia will decline to recognize the diploma of any college which does not conform to the requirements of the Association of Medical Colleges. Applicants must also pass an examination.

The examination comprises the following subjects: Hygiene and Medical Jurisprudence, Anatomy, Physiology, Chemistry, Histology, Pathology and Bacteriology, Materia Medica and Therapeutics, Obstetrics and Gynecology, Practice and Surgery. A total average of 75 per cent. shall be necessary, provided, that in no one section shall the percentage be less than 45.

The fee for the examination is $10; those failing to pass the examination will not be required to pay further fee when they appear for re-examination.

Reciprocity: The following resolution in regard to reciprocity was adopted by the Virginia Board at its meeting held at Lynchburg, June 25-28, 1900:

"*Resolved*, That the Virginia State Medical Examining Board desires to reciprocate with the Boards of other States, but deems it necessary for its own protection that every applicant claiming such recognition shall present with his petition a diploma from a reputable college, together with an attested certificate from a State Medical Examining Board, having same requirements as our Board, and shall pass a satisfactory oral examination before a committee of the Board. Having complied with these requirements, a certificate will be issued on payment of the usual fee."

Secretary of Medical Examining Board, R. S. Martin, M.D., Stuart, Va.

Washington.—Applicants must be over twenty-one years of age, must present a written recommendation of good moral and professional character from two physicians in good standing, and must have graduated from some duly authorized and recognized medical college now having at least a three years' graded course. The examination is in the following subjects: Anatomy, Physiology, Chemistry, Histology, Materia Medica and Therapeutics, Preventive Medicine, Practice of Medicine, Surgery, Obstetrics, Diseases of Women and Children, Diseases of the Nervous System, Diseases of the Eye and Ear, and Medical Jurisprudence. "The examination shall be both scientific and practical, and of sufficient severity to test the candidate's fitness to practise medicine and surgery." Candidates who have practised ten years or over are required to obtain a general average of 70 per cent.; those who have practised less than ten years are required to obtain an average of 75 per cent. The fee for the examination is $10. Examinations are held alternately in Eastern and Western Washington, at such places as the board may designate, on the first Tuesday of January and July. The next examination will be at Spokane, on first Tuesday of July, 1904.

Reciprocity, none.

Secretary of State Board of Medical Examiners, P. B. Swearingen, M.D., Tacoma, Wash.

West Virginia.—All applicants must be examined. "Applicants for the board's examination will present to the secretary of the board for verification their diplomas, medical certificates which evidence their academic and professional labors, and present a certificate of good moral character signed by two physicians in active practice in the county of their legal or actual residence. When applicant fails to produce evidence of proficiency in general or high-school education, the board reserves the right to examine him in English, Easy Latin, and in Arithmetic, Algebra, and Geometry." The examination will cover the following subjects: Anatomy, Chemistry, Physiology, Materia Medica and Therapeutics, Practice of Medicine, Bacteriology, and Histology, Hygiene, Obstetrics, Gynecology, Surgery. The fee for the examination is $10.

Examinations are held not less than three times a year, in April, July, and November, at places convenient to applicants, or to the Board of Health.

Reciprocity, none.

Secretary of the State Board of Health, Hugh A. Barbee, M.D., Point Pleasant, W. Va.

Wisconsin.—"All applicants must present evidence of good moral character; also a diploma from a reputable medical college requiring a four years' course of at least seven months each before graduation, no two of such courses to be taken within any one twelve months, and that shall require for admission thereto a preliminary education equivalent to that necessary for entrance to

he junior class of an accredited high school in this State, including a one year's course in Latin, and hat shall, after the year 1906, require for admission o such school a preliminary education equivalent o graduation from an accredited high school of his State." Applicants must also pass an examiation in Pathology, Surgery, Obstetrics, Gynecology, Anatomy, Materia Medica, Practice of Medicine, Dietetics, Jurisprudence, Therapeutics, Physiology, Hygiene, Diagnosis, Toxicology, Histology, Bacteriology, Chemistry, Uranalysis. "A general average of 75 per cent. shall be necessary, provided that in no one branch shall the percentage be less than 60. The fee for the examination and license is $20. If license is not granted, $5 will be returned to the applicant.

Regular meetings will be held on the second Tuesday of July at Madison, and of January at Milwaukee; or examinations will be held at such time and place as the board may determine, notice of which will be given upon application to secretary.

Reciprocity: "Graduates of reputable medical colleges with a certificate from any State board whose requirements are equal to those of this State, may be admitted to practise without examination at the discretion of the board." At present Wisconsin reciprocates with Illinois, Indiana, Kentucky, Maine, Maryland, Michigan, Nebraska, and Ohio.

Secretary of the Board of Medical Examiners, Filip A. Forsbeck, M.D., 121 Wisconsin Street, Milwaukee, Wis.

Wyoming.—The applicant, "if a graduate in medicine, shall present his diploma to the State Board of Medical Examiners for verification as to its genuineness. If the diploma is found to be genuine, and issued by a medical college of recognized merit, said college being a member of the American Association of Medical Colleges, the Homœopathic Institutes, or the National Eclectic Medical Association, or any college of similar standing in foreign countries, and if the person named therein be the person claimed and presenting the diploma, the State Board of Medical Examiners shall issue its certificate to that effect, signed by the majority of all the members thereof, with the seal of the board attached, and such diploma and certificate shall be conclusive as to the right of the lawful holder of the same to practise medicine in this State; provided, no person holding diplomas, certificates, or other credentials from schools or institutions other than those of recognized merit, as specified in this chapter, shall be permitted to practise in this State, until he has passed a satisfactory examination before said board. Said examination shall be in whole or in part in writing, and shall be of an elementary and practical character, and shall be upon the following subjects: Anatomy, Physiology, Chemistry, Pathology, Materia Medica and Therapeutics, Hygiene, Theory and Practice of Medicine, Surgery and Obstetrics, and sufficiently strict to test the qualifications of the candidate as a practitioner." Fee, if diploma is accepted, $5; if examination is taken, $25.

Examinations are held at any time as required.

Reciprocity, none.

Secretary of the State Board of Medical Examiners, Dr. Geo. P. Johnston, Cheyenne, Wyo.

306 West Ninety-third Street.

Typhus in Africa.—Captain Dannhauer, the correspondent in German South Africa of the *Lokal Anzeiger* of Berlin, has cabled from Windhock that the number of soldiers suffering from typhus fever in the hospitals at Otjihaenena, Winkhoek, Opahandya, and Karibb is one hundred and seventy-five.

Volvulus of the Stomach.—C. D. Spivak concludes that: (1) The occurrence of volvulus of the stomach is a possibility beyond the shadow of a doubt; it remains, therefore, for physicians to bear this condition in mind when making a differential diagnosis between pyloric obstruction, occlusion of the bowels, poisoning, cyclic vomiting, cholelithiasis, peritonitis, etc.; for surgeons to be ready to operate when necessary, and not to forget to empty the stomach of its contents; and for authors to devote some space to this condition in their textbooks on diagnosis and surgery. (2) Volvulus of the stomach occurs in all ages and in both sexes. (3) Digestive disorders may be considered as etiologic factors. (4) From the pathologic standpoint, volvulus of the stomach may be divided into (*a*) that due to organic changes produced by adhesions, and (*b*) that in which no visible organic changes have taken place. (5) The characteristic symptoms of volvulus are: Sudden onset; distension which commences in the left hypochondriac region, and which gradually increases in size; a tumor, which gives, on percussion, a tympanitic sound; vomiting or regurgitation immediately following ingestion of food or drink; no belching, no escape of flatus; inability to pass a sound into the stomach. (6) When the condition is recognized, early operative interference is indicated, and recovery is almost certain.—*Denver Medical Times.*

The Oats Cure in Severe Cases of Diabetes Mellitus.—Carl Von Noorden gives a preliminary report of his work along these lines. He uses oatmeal or oat groats. He boils the substance in water for a considerable length of time with the addition of a little salt. While boiling, butter and some vegetable albumen, or after cooling off, beaten white of an egg, is added. Roborat or rice albumen is commonly used. The usual daily doses at the beginning of treatment are 250 gm. oats, 100 gm. albumen, 300 gm. butter. The soup thus prepared was given every two hours. In addition, a little brandy or wine and a little strong black coffee were allowed. The author then appends a series of cases. The first one is that of a patient in whom the use of the strictest diet for twelve days did not free the urine from sugar. The oats cure was instituted. From day to day the sugar has diminished and acetone was seen to be normal on the third day. Sugar was noticed only temporarily upon a gradual return to a mixed diet (thirty-seventh to forty-seventh day). Beginning with the forty-ninth day, the patient thrived on ordinary strict diet, which formerly had forced 50 gm. of sugar into his urine, and finally it was possible to add to the conventional diabetes diet considerable quantities of various carbohydrates without reëxciting glycosuria. Since the patient was discharged, a weekly examination of urine since that date has shown no trace of sugar. Acetone is present in normal quantity only. The general condition is excellent. The writer declares that, according to his experience, mild cases without diaceturia do not do well under the oats cure, and as a rule, lose in tolerance if the treatment is persisted in. How to account for the paradox effects of the oats cure must be left to conjecture. The fact has been pointed out before that a very simple diet rich in carbohydrates is better borne by diabetics than a mixed diet poor in carbohydrates. The latest facts adduced make it more than ever incumbent upon the physician to abstain from treating a diabetic patient by any standard formula and to substitute strict individualization. The question of diet is to be approached cautiously even by the most experienced practitioners. While the writer recommends a trial of the new method for a certain number of cases, the characteristics of which he is as yet unable to define, he adds a decided warning against treating every case of diabetes by this method without a fixed plan. For, as against the few who are actually benefited there are those to whom the method is of no advantage and a still greater number who might be seriously injured thereby.—*The Post-Graduate.*

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

THOMAS L. STEDMAN, A.M., M.D., ASSOCIATE EDITOR.

PUBLISHERS

WM. WOOD & CO., 51, FIFTH AVENUE.

New York, May 28, 1904.

THE POST-GRADUATE PERIOD.

Two grave problems confront the young man on the threshold of life who has failed to select his ancestors among those well favored with this world's goods. The first of these is the choice of a vocation; the second, how to make a successful start in the chosen calling. The medical student has made his selection, whether wisely or not depending upon certain personal qualities which need not enter into discussion here; in most cases the choice is unalterable and there remains only the question of how he shall turn to best advantage to himself and to his fellows the knowledge and skill with which his college and hospital training should endow him. To the man with influence or with the means of support during the necessary years of waiting, this question is of little moment; he is either inducted at once into the active practice of his profession under the guidance of an experienced elder, or he waits with what patience he can command until a clientele is built up, employing his abundant leisure in the meantime to pursue his studies and fit himself more fully for the responsibilities that are sure to come. To the young graduate without means or influence, however, the problem of subsistence becomes at once a most serious one.

In the present number of the MEDICAL RECORD will be found a series of articles, written by men of experience and practical knowledge of the topics of which they treat, designed to point out to the young physician the opportunities offered him of making a living outside of regular practice. These may be roughly divided into three classes—those which offer a permanent career outside of civil practice, such as the public services; those which offer only a temporary assistance, such as most of the municipal appointments; and those which offer a more or less permanent supplement to the income from private practice, such as appointments as insurance examiners, railway surgeons, surgeons to the police and fire departments in the larger cities, etc.

It will surprise some of our readers, no doubt, to learn how many ways there are of increasing one's income in a method not inconsistent with professional dignity, and we hope many will be helped by the information here given to bridge over the critical period of beginning professional life. A word of caution is, however, necessary. The man who wants to succeed in general practice must look on these various helps as temporary makeshifts, and form the resolution and adhere to it, to give them up as soon as his practice will support him. If, seduced by the security which a salary, however small, gives him, he follows the extra-professional, or rather extra-practical, calling too long, he will in the end become dependent upon it, and the demands it makes upon his time and strength will seriously handicap him in the race for success in practice.

It is different, of course, with the public services and some other positions which carry with them a living salary from the beginning. These offer the young physician a career outside of private practice, and should be taken up only as a life work. The man who enters the Army, the Navy, or the Marine-hospital Service with the idea of remaining there only a few years and then resigning to enter upon private practice, makes a fatal mistake. The training he receives in these services is not well adapted to fit him for civil practice, and his salary in the early years is hardly more than enough for daily needs, so that it will be practically impossible to save a sum sufficient for support during the waiting period.

It is not, however, for the necessitous only that this number of the MEDICAL RECORD has been prepared. The college and hospital graduate, however well fitted he is, is not yet entitled to practise his profession. The State demands that he once more demonstrate his fitness for professional work before becoming legally qualified to treat the sick. The laws on this point unfortunately differ in the different States, and one who would settle in any locality must acquaint himself with the provision of the medical law for that particular State. All needed information in this respect, as well as practical hints regarding the preparation for examination, etc., will be found in the article on this subject by Dr. Scott.

The legal rights and obligations of the physician should be thoroughly understood by the young practitioner who would avoid the annoyance and expense of a possible malpractice suit, or the chagrin of being unable to establish his claim for professional services rendered those able but unwilling to pay. All that is necessary for him to know in this regard may be learned from the very practical article by Mr. Taylor in this issue.

The time has gone by when protests against the practice of medicine by women can be entertained; but though the woman has obtained equal rights with her male colleagues she has yet to secure many of the privileges which man enjoys. Few of the aids to a livelihood treated of in this issue are open to her, yet that there are some ways by which she can eke out the scanty income of early practice can be learned from Dr. Walker's interesting article.

Finally, Dr. Roosa warns the recent graduate that the necessity for work does not cease with graduation, but that he must keep in constant touch with the progress of his science by post-graduate study—and, we may be permitted to add, by the regular reading of a progressive medical journal. Indeed the recent graduate, whatever his needs or his aims, will find here advice and guidance which cannot but serve him in the choice of and preparation for his future career in one of the callings open to medical men.

THE ETIOLOGY OF ACUTE RHEUMATISM.

THE *Journal of Pathology and Bacteriology* for December last contains an article by W. V. Shaw, and the number for March another by J. M. Beattie, on this subject. Although as far back as 1887, Popoff reproduced the lesions (arthritis, pericarditis, endocarditis) by the injection of a microorganism isolated by him, little attention was paid to his results. In 1891 Achalme isolated an anthrax-like bacillus which he regarded as causal, and in 1896 Thiroloix reproduced the whole picture of rheumatic fever by intravenous injection in rabbits of a microorganism apparently identical with Achalme's bacillus. Still, in view of the partial successes and partial failures, the subject remained in abeyance till the publication, in 1900, of the work of Poynton and Paine, the latter having started with the expectation of confirming Achalme's results. These observers isolated in eleven (later in eighteen) cases a diplococcus from which in five cases they obtained a pure culture, and which injected intravenously into rabbits produced the symptoms of rheumatic fever (polyarthritis, pericarditis, valvulitis, chorea). The organism was also recovered in pure culture from the joint exudations, heart blood, urine, and cerebrospinal fluid, of the rabbits. The authors concluded that the organism is "a cause of rheumatic fever." And in 1903 Beaton and Walker announced that they had isolated a similar diplococcus from fifteen cases and had reproduced in rabbits typical acute rheumatism.

Shaw gives the results of a number of inoculation experiments upon rabbits and monkeys. Of the latter, two in number, one showed clinically acute rheumatism, and post mortem, arthritis, pericarditis, and endocarditis. The second, still alive, showed a disease bearing a close and unmistakable resemblance to acute rheumatism in children; fever, inability to use legs, the joints of which were not swollen, hot, and tender), and a distinct systolic murmur, especially close to the left nipple, the murmur never having been audible before the illness. Shaw remarks that this microorganism from the human subject breeds true, reproduces the lesions on inoculation, and can be recovered from the reproduced lesions in pure culture.

Beattie's case was a girl of sixteen, who had had rheumatism at seven and nine, cardiac disease accompanying the latter attack. At fifteen acute rheumatism (polyarthritis, loud presystolic and systolic murmurs, no increase of cardiac dulness), with, on sixth day, increase of cardiac dulness to left and right; and very rapid dicrotomous pulse; great dyspnœa, cough with bright, frothy, blood-stained sputum, and numerous medium and fine crepitant râles over right lung, and friction over right axilla, and base behind, and to right of sternum; and death on the seventh day. The autopsy showed a slight mount of turbid fluid in pericardial sac, and general thickening of pericardium with a slight amount of recent lymph over the right auricle; a few petechial hemorrhages in the grooves between the auricles and ventricles; mitral cusps much thickened with recent vegetations, old thickening of the aortic cusps; small pinkish areas scattered through the heart muscle suggestive of acute myocarditis; general dilatation, but no incompetence of valves; very slight patchy congestion of synovial membrane of knees. Cultures from the last named places yielded a minute microorganism in pairs and short chains which corresponded in reactions and cultures to Poynton and Paine's diplococcus. A rabbit inoculated intravenously from subcultures made in tubes, showed on the third day, lameness of one hind leg; on the fourth a suspicious systolic murmur, distinct on the fifth; and, killed six days later, marked endocarditis with large vegetations on the aortic cusps and dilatation of the left ventricle; a pale recent infarct in right kidney; non-purulent fluid in right knee and left ankle-joints with the synovial membrane thickened and somewhat gelatinous. The diplococcus was recovered in pure culture from the vegetations, joints, and urine. The vegetations contained the diplococcus in numbers, while the infarct showed none.

Beattie concludes that in the light of all the work done, it is impossible to resist the conviction that acute rheumatism, and its associate chorea, is a bacterial disease. The only question is whether the microorganism is a specific one. The fact that in most cases of rheumatism organisms are not found is only what might be expected, as the disease is rarely fatal in the acute stage. Moreover, the diplococcus is very minute and might very easily be overlooked, and besides it seems to be very easily destroyed in the tissues. The presence of streptococci, pneumococci, and other organisms does not signify until they shall have been proven capable of transmitting the disease. They are liable to be deposited on any damaged area. Up to the present time only two organisms have been shown experimentally to produce acute rheumatism, namely, Achalme's bacillus, and the diplococcus described by several observers? It is highly improbable that later observers with their attention focussed on the point by previous work, could have overlooked the former of these organisms, while, on the other hand, it is quite possible that the first observers might have overlooked the diplococcus. At present, therefore, the weight of evidence is in favor of the diplococcus as the causal agent.

INSPECTION OF THE SOURCES OF THE OYSTER SUPPLY.

TYPHOID FEVER occurs so frequently in the cities of the United States—even in New York the disease is by no means uncommon—as to render the source of infection a matter of the greatest moment. The chief causes of typhoid fever in most American cities are obvious. Contaminated water supply, impure milk and inefficient sanitary arrangements generally are the most prominent factors in originating and in spreading an epidemic of the malady. New York, however, prides herself—and justly, too—upon possessing a good water supply and an efficient sanitary system. The milk supply is fairly good, but is probably the origin of many of the sporadic cases of typhoid fever which crop up at intervals, though it does not account for all. Whence, then, proceed the infective agents responsible for the remainder? To two causes these cases of typhoid fever are usually attributed: to infected oysters and to infected vegetables.

During recent years the oyster has been regarded with grave suspicion in this connection. Indeed, in several instances in England the case against the

shell fish as a conveyor of typhoid infection has been proved up to the hilt. The danger now would seem to be that the prevalence of this mode of infection should be exaggerated.

Nevertheless, there is little doubt that oysters are guilty of causing typhoid fever in a large number of cases. Granted, then, that typhoid fever is more or less frequently transmitted by means of oysters, and that the water supply and sanitation of New York are satisfactory and that the milk supply is fairly good, it is only reasonable to lay to the charge of infected oysters a certain proportion of the cases which occur in this city.

The Department of Health has at any rate taken this view of the question and has lately caused the sources of the greater part of the oyster supply of New York to undergo inspection.

The *New York Independent*, May 12, referring to the subject editorially, says: "Most of the oysters that are sent to New York in the regular course of the trade are provided with many opportunities of becoming infected with sewage material of varying degrees of virulence. Along the Sound shore of Long Island, or of Connecticut, or in Staten Island, or in New Jersey, oysters after gathering are exposed for some time to contamination by being placed in the waters of little streams that run out into the salt water and carry down with them the sewage and drainage of neighboring villages and of various factories and farms along the banks. This subject has not been investigated merely by casual inspection, but definite, incontrovertible records of what inspectors observed have been preserved by means of photographs. At a meeting of the Medical Society of the County of New York, held on April 25, photographs were exhibited as stereoscopic slides, with proper explanation of their significance by Dr. Walter Bensel, acting Sanitary Superintendent of the Department of Health of New York City. The oysters are stored before shipment for several days, as a rule, in oyster houses, the lower floor of which is below the level of the water, or in oyster floats, through which the water is allowed to find its way. These and floats are usually placed some distance up various little streams. It has been found that if the water that flows over the oysters is not entirely salt, the shell-fish become plump, and are somewhat bleached, thus looking more inviting to the untrained in oyster lore. This process is known as fattening. . . . Many of the photographs exhibited show the existence of privies and other sources of the worst forms of sewage, situated either on the banks of the streams or in close proximity. In most of the streams the ebb and flow of the tide prevent even that carrying away of floating material common in ordinary country streams."

The result of investigations in Great Britain has been to prove conclusively that infected oysters have been the cause of some serious epidemics of typhoid fever. The findings of the recent inspection by the New York Health Board support these conclusions, and show that many sporadic cases of the disease in this city may have been and probably were due to contaminated oysters. Possessing this knowledge, the remedy is not difficult. In the first instance, oyster beds should be placed in such a situation that the water in which they lie cannot under any circumstances become contaminated; and secondly, while oysters are being prepared for the market they should not be permitted to come into contact with other than pure and wholesome water. Regulations to this effect might be enacted. The present methods are a distinct menace to the public health, and a person eating oysters, ignorant of their source, is running a serious risk. The New York City Department of Health has rendered valuable service to the community at large by ordering the inspection of the sources of the oyster supply and by publishing the results of their investigations.

The Necessity of Disinfection of Railway Property.

Dr. M. J. Rosenau read a paper dealing with this matter at the meeting of the New York State Association of Railway Surgeons on November 14, 1901. There is no doubt that disease is more or less frequently spread by those who travel when suffering from a communicable malady, and that railway traveling is to a certain extent a source of danger to death from this cause. Dr. Rosenau, at the beginning of his paper, considers this question: Is it necessary to disinfect the railroad coach, the sleeping car, the railroad station, the yard, even when no case of contagious or infectious disease has been known to have contaminated these places? and concludes that it is necessary for the reasons that all such diseases may exist in latent or mild form, so that they are difficult to recognize. Diphtheria, for instance, may be easily communicated by using a drinking glass, or towel which shortly before has been put to the lips or mouth of an individual who may have virulent diphtheria bacilli in his mouth, without having any local lesions or constitutional disturbance. Mild cases of smallpox which cannot be recognized as such, may be disseminated and infect the railroad coach, while the same may be said of typhoid fever, scarlet fever, measles, cholera, yellow fever, plague, and the whole list of pestilential diseases.

"There are, says the writer, evils of construction in the modern railroad car responsible for much of the infection and the difficulty of eradicating it. With the spitting, hawking, and blowing of the nose into the wash bowl—everybody washes their teeth over these bowls, for no other place is provided—it is no wonder that they frequently convey infection. It is unfortunate, as Dr. Hurty points out, that a special sink is not furnished in the toilet room of the coach for the teeth-cleaning process."

Railway cars, too, are ornamented and molded to so great an extent as to provide convenient harboring-places for dust, dirt, and infection. The upholstering is gorgeous but insanitary to a degree. So far as the berth in the sleeper is concerned, no more convenient mode of conveying infection could scarcely have been devised. Sheets and pillow-slips may have been changed, but there still remain the blankets, and all the other surfaces that have been so carefully closed up, almost hermetically, against the fresh air and sunshine during the day. The necessity of the frequent disinfection of the sleeping coach is too obvious to need further emphasis.

With regard to the arrangement of the water-closet on the passenger coach, Dr. Rosenau has this to say: "There is little doubt in my mind that typhoid fever is spread broadcast throughout the length and breadth of the land by means of the primitive and offensive open hopper. There are many patients with typhoid fever traveling in railroad trains. Some are walking cases, some are convalescent, some have the disease developing. From the nature of the disease, these patients use the closet

frequently, and their discharges, laden with typhoid bacilli, are dropped along the route and smear the underside of the car, to be splashed and spattered in all directions. Some of these discharges may directly contaminate the water supply of towns and cities by falling into the river as the train crosses the bridge; some may do so indirectly by being washed into the water-courses along which the railroad so frequently runs, others, in the country, become the breeding and feeding places for flies, which carry the infection to the nearest farmhouse."

The foregoing is a phase of the subject which requires close attention. The evils of the present water-closet system of the American railroads have not been in any way exaggerated by Dr. Rosenau. They are undoubtedly a fertile source of spreading typhoid fever, and the matter should be looked into carefully and steps be taken to minimize the resulting danger by those responsible for the safety of the traveling public. The community at large does not appreciate the menace to health threatened by the open hoppers, but the subject should be ventilated and pressure be brought to bear upon the railroad authorities to put an end to a method which is offensively dirty and at the same time in a higher degree inimical to health. It is said that the evolvement of a satisfactory solution of the problem is extremely difficult, but it is a question of so great importance that it behooves the engineering departments of railroads to spare neither time nor money in finding a remedy for the existing unhealthy state of affairs.

Street Locomotion in New York City.

The figures supplied by the New York State Railroad Commission show the extent to which New Yorkers use their local transportation lines, and is a further argument, if such were needed, that means to relieve the present state of congestion are a vital necessity. The methods in use now for carrying New Yorkers to and fro on business or otherwise are notoriously inadequate and have given rise to a condition of things not only inconvenient but prejudicial to health and against the laws of decency.

For the year ended February 29, 1,036,834,773 passengers were carried on the surface and elevated roads of the five boroughs, an increase of 65,075,964 over the previous year. This was a total car mileage of 197,826,719, an increase of 18,220,741. The surface lines, however, did not show any appreciable increase, and it was stated that this was because the company had reached its limit under present conditions, with its total of passengers of 397,644,829. The elevated lines in Manhattan carried 273,133,242, the gain being 37,315,852. The total for the year in Manhattan was 670,778,071 passengers, an increase of 37,463,163; in Brooklyn the number of passengers carried on all lines was 320,107,163, an increase of 24,363,201. In Queens the total was 16,058,207, an increase of 762,354. In Richmond all roads carried 7,744,255 passengers, an increase of 498,610.

Reply to the Physiological Sub-committee of the Committee of Fifty.

Mr. Gallinger presented a document, No. 171, to the national Senate, containing a reply to the physiological sub-committee of the Committee of Fifty, by Mrs. Mary H. Hunt, world and national Superintendent of Department of Woman's Christian Temperance Union. The document was ordered to be printed. The sub-committee, after a lengthy and careful consideration of the present system of scientific temperance instruction in the public schools of the United States, concluded that the teaching as at present conducted was not exactly scientific and was also too one-sided. (1) They object to instruction being given to all pupils in all schools instead of being confined to the older pupils, especially those in the high school. (2) They object to it as frankly and honestly a total abstinence movement. (3) They cite for criticism the teaching that alcohol is not a food, but a poison. Mrs. Hunt in her reply endeavors to show: (1) That no evidence is presented by the sub-committee to prove that alcohol is a food in the sense in which the word is commonly understood. (2) That no evidence is presented by the sub-committee that alcohol is not a poison according to standard definitions of the word poison. (3) That no evidence is presented by the sub-committee that anyone who attempts the beverage use of alcoholic drinks, even with meals after the day's work is done, can be sure that he will not fall a victim to the alcoholic appetite. Hence they do not prove that moderate drinking is safe. (4) That no evidence is presented by the sub-committee that confining the study of temperance physiology to the older pupils, especially those in the high school, would not introduce it too late, after cigarette and other wrong habits may have been formed, or after an overwhelming majority of the pupils have left the school. Therefore, in the opinion of Mrs. Hunt, the Physiological Sub-committee have not proved the indorsed physiologies inaccurate on the above points, or that confining the teaching to the older pupils would be either wise or safe.

With regard to temperance in the use of alcohol, the Medical Record has always strongly advocated the strictly scientific interpretation of stimulation. The promoters and followers of the temperance movement in their zeal for the furtherance of their beliefs will listen to no argument from those who hold with moderation. They argue that if a large amount of alcohol does great harm a smaller quantity must necessarily do harm to a lesser extent. There is no proof that this is so,—indeed, as Sir James Paget pointed out, the facts are the other way. Large quantities of quinine will make a man, at least for a time, deaf and blind; smaller quantities may do nothing of the kind, but may cure his ague; and yet smaller doses may leave him with his ague and all his senses unaffected but may improve his appetite. One quantity of arsenic may kill any man; another much smaller may strengthen him or cure his neuralgia or some disease of his skin.

So far as the teaching of the public schools respecting the physiological action of alcohol is concerned, there can be no great objection to it provided that such teaching is in agreement with the opinions of the most eminent authorities on the subject. It would be interesting to learn the source from which the present method of physiological teaching was drawn, whether from the writings of the best known authorities or only from those whose views chime in with the views of the advanced temperance section. The fact must be borne in mind that the greater weight of argument rests with the men who believe in moderate drinking and not in total abstinence. At any rate, it would seem that the sub-committee are perfectly right in insisting that young children should not be taught the harmfulness of alcohol from a physiological standpoint. Even if the subject be taught fairly, they cannot understand, are apt to become wearied, and instead of doing them the good intended, the reverse is the case. Mrs. Hunt and her followers are enthusia tic in the cause of temperance, and for this are worthy of the highest commendation, but some of their

zeal has been diverted into misdirected channels, one of which is the teaching of the physiological action of alcohol in the public schools.

Typhoid Fever in Philadelphia.

Although the cities of the United States are improving in sanitary matters, they are for the most part far behind some of the European large towns, —notably those of Germany and Great Britain— in this respect. One of the most reliable gauges of efficient sanitation is the freedom of a locality from typhoid fever. If this disease frequently occur then the sanitary arrangements, and particularly the water supply, must be viewed with grave suspicion. Judged by this standpoint, there are unfortunately a large number of cities in this country which, if weighed in the balance, will be found wanting. Among the large centers of population, to which attention is continually being drawn by oft recurring epidemics of typhoid fever, Philadelphia is the most prominent. Typhoid fever and Philadelphia are almost synonymous terms. The hope expressed that an abatement of the typhoid death rate of the Pennsylvania city was at length in sight, has not been borne out by recent official statistics. These figures show that during the week ending May 15, 297 new cases and 38 deaths were reported. The disease, too, is now epidemic in nearly all parts of the city and there are no signs of its decrease. Since January 1, 4,051 cases and 361 deaths have been reported.

Under the circumstances it is difficult to resist the conclusion that the sanitary authorities of Philadelphia have not grappled with the matter in a sufficiently energetic way. It would appear, that there has been either too much laxity in performance on the part of the local sanitary administration, or that there is a lamentable lack of expert knowledge among Philadelphia sanitarians. Be the cause what it may, it is a decided blot on the government of the Quaker city that a preventable malady like typhoid fever should be allowed to spread almost unchecked. Lessons as to the best methods of dealing with this disease can be easily obtained in many European cities and in a few American cities, and for the sake of the fair fame of Philadelphia it would be fitting that measures be taken to stay the course of typhoid fever and to prevent its frequent recurrence.

The Practice of Medicine in New York City.

A case which has recently been decided in New York City, throws much light upon the manner in which the laws regulating the practice of medicine in New York State are not infrequently evaded. The case in question was brought by the Medical Society of the County of New York against an individual, who, in the opinion of the society, had contravened the medical laws of the State.

The defendant advertised himself as a physician of natural cure and balneotechnic, and stated that he cured all kinds of diseases without medicine or instrument, by means of massage and heat gymnastics, magno-electro and hydropathic treatments. He also provided all kinds of cure-baths, herbs, mineral, sulphur, iron, lithia, pine-needle, aromatic and all medicated baths. Blood purifying and good complexion a specialty. Massage, steam, hot air, vapor, and astringent baths for males, females, and children. Prices liberal.

The point to be decided was as to whether the defendant had practised medicine without registration—that is to say, whether he had undertaken to diagnosticate and cure disease. The witnesses called, one of whom was an agent for the New York County Medical Society, proved to the satisfaction of the court that he had done so, and the defendant was sentenced to pay a fine of $100, and in default of payment to be committed to the New York City Prison for a term of thirty days. An example might with advantage be made of many like fakirs, who prey upon the ignorance of the public and who take the bread from the mouths of legitimate medical practitioners. The law as to medical practice should be scrupulously enforced.

News of the Week.

Health-Board Diagnosis of Cerebrospinal Meningitis.—Owing to the prevalence in the city of epidemic cerebrospinal meningitis, the Department of Health offers to place at the disposal of hospitals and medical practitioners the service of its laboratories to aid in the diagnosis of this disease. The meningococcus is found in the cerebrospinal fluid of the majority of cases, and usually also in the nasal secretion. The Department of Health will examine free of charge specimens of cerebrospinal fluid, as well as smears of, and cultures from, the nasal secretion. Such examination will in many instances assist in the early recognition of the disease, and in determining the nature of obscure cases. Special outfits, consisting of a blood-serum culture tube, a sterilized swab, and a glass slide for the smear, can be obtained at the Department of Health, Fifty-fifth street and Sixth avenue. After the specimens have been obtained they should be sent at once to the Department. Reports will be sent by telephone and mail. Specimens of cerebrospinal fluid can be readily obtained by lumbar puncture, a simple operation easily performed by the attending physician himself, or any surgeon. The operation, in addition to being an aid in diagnosis, is directly beneficial because of the relief of the intraspinal pressure.

The American Medical Temperance Association.—The thirteenth annual meeting of this association will be held in the parlors of the hotel Dennis at Atlantic City, June 8 and 9. There will be an address "On the Effects of Alcohol on the Structure of the Body," by the honorary president, Dr. N. S. Davis of Chicago, and also "A Review of Late Researches Concerning Alcohol as a Drug in Medicine," by Prof. W. S. Hall, the president. Other papers on allied topics will be read by Drs. Mann, Nichol, Crothers, Mason, Kellogg, Reynolds, Steward, Reese, Paulison, Madden, and others. "The object of this association is to encourage and promote the clinical, therapeutical, pharmacological and chemical study of alcohol in health and disease. It also aims to gather, compile, and make available the studies and experiences of medical men in all parts of the country concerning the use of alcohol and to formulate such definite facts as can be utilized and made available in the practice of medicine. The spirit and purpose of the association is a purely scientific one, concerning the nature and the character of alcohol, irrespective of all possible conclusions. Regular practitioners of medicine may become members by a two-thirds vote of the association after signing an application to the secretary. All persons interested in this great topic are earnestly invited to attend the annual meeting." Further particulars may be obtained by adressing T. D. Crothers, Secretary, Hartford, Conn.

Evening Meetings of the American Medical Association.—In addition to the orations to be delivered as usual at the general sessions of the annual meeting

t Atlantic City, there will be on each of the first ree evenings a number of minor addresses on arious subjects. At the first meeting, following e Oration on Medicine by Dr. George Dock of nn Arbor, Mich., there will be given by Dr. J. S. illings of New York an account of the work of the arnegie Institution; Dr. L. Emmett Holt of New ork will speak of the Rockefeller Institute; Dr. rank Billings of Chicago of the Memorial Institute r Infectious Diseases; Dr. Harold C. Ernst of oston of he research work at Harvard, and Dr. lfred Stengel of Philadelphia of the William Pepper inical Laboratory. Wednesday evening Dr. W. Mayo of Rochester, Minn., will deliver the Ora- on on Surgery. Following this Dr. Victor C. aughan of Ann Arbor, Mich., will talk on the sub- ct "What Can the Medical Departments of the rmy, of the Navy, and of the Public Health and arine-Hospital Service Do for Medical Science?" rgeon-Major William C. Borden, U. S. Army, ill speak on "What Can the Medical Profession o for the Army?" Surgeon C. F. Stokes, U. S. avy, will speak for the Navy, and Surgeon-General alter Wyman will speak for the Public Health and arine-Hospital Service. Thursday evening the ration on State Medicine will be delivered by Dr. erman M. Biggs of New York City. Following this r. William H. Welch of Baltimore will speak on The Bureau of Animal Industry; Its Service to edical Science"; Dr. D. E. Salmon of Washington, . C., on "The Service of the Medical Profession the Bureau of Animal Industry," and Dr. H. W. Wiley of Washington, D. C., on "The Bureau f Chemistry and Medical Science."

Faculty Reorganization at the University of Pennsylvania.—A plan for the reorganization of the aculty has just been approved by the board of rustees, whereby the faculty membership has been xtended to the clinical, associated, and assistant rofessors, to the associates and lecturers, and to mited representation from the subordinate staff. he scheme provides for an executive body or coun- il, to be composed of the heads of the departments a the fundamental subjects and two representatives f the specialties. The plan will be put into effect n September 1 of the current year.

A New Women's Dispensary.—The articles of in- orporation of the Bedford Guild Dispensary, which ave the approval of the State Board of Charities, ere filed in the County Clerk's office in Brooklyn st week. The object of the organization, as stated a the charter, is to provide medical and surgical id for women and children by women physi- ians.

Gift to the Manhattan Eye, Ear, and Throat Hospital.—It is stated that conditional donations to the mount of $125,000 are now assured to this institu- ion by a gift of $40,000, needed to meet the condi- ions, by Mr. Edward R. Thomas of this city. A ite for the new building has been secured on Sixty- hird and Sixty-fourth streets, east of Third avenue. t is not far from where the Rockefeller Institute is o be built.

The Woman's Hospital.—The corner-stone of the ew Woman's Hospital was laid on May 17. Mr. ohn E. Parsons, president of the hospital, made he principal address. The new hospital will be six tories high, of steel and brick, with fancy trimmings. The building will have a frontage of 200 feet on One hundred and tenth street, and will extend through to One hundred and ninth street. There will be two wings in the shape of the letter U. When completed the new building will have cost a little over $1,000,000.

Typhoid Fever in Philadelphia.—Notwithstanding the lateness of the season there seems to be no abatement in the typhoid-fever epidemic in Philadelphia During last week 297 new cases were reported and 38 deaths. Until quite recently the disease was largely confined to West Philadelphia, but it is now epidemic in nearly all parts of the city. Since January 1 there have been 4,051 cases reported and 361 deaths, showing a mortality of very nearly 9 per cent.

Michael Reese Hospital Receives $400,000.—This amount has been raised by the committee of eight for the erection of a new hospital by this name, and at the joint annual meeting of the Board of Directors of the United Hebrew Charities, and the Associated Jewish Charities, Leon Mandel, Edwin G. Foreman, W. N. Eisendrath, Moses Born, Julius Rosenwald, Maurice Rosenfeld, Moses E. Greenbaum, and Herman F. Hahn, were appointed a building committee, with power to act.

Philadelphia Hospital.—As a result of the examination held recently for the position of interne forty-one of the eighty-five applicants passed the civil-service examination and are thus eligible for election. There are nineteen vacancies to be filled from time to time, and these will be assigned to those who attain the highest averages. Should any of these decline to serve, the positions will be offered to those who stand next in order in the list. Of the first nineteen, eleven are graduates of the University of Pennsylvania; six graduates of Jefferson Medical College, and two graduates of the Medico-Chirurgical College. Of the remainder, fourteen are graduates of the University of Pennsylvania; four graduates of the Medico-Chirurgical College; three graduates of Jefferson Medical College, and one is a graduate of the Woman's Medical College of Pennsylvania.

Indiana State Medical Association.—The Indiana State Medical Association closed its annual convention May 20, with the election of the following named officers: *President*, G. T. McCoy, Columbus; *Vice-Presidents*, H. J. Hall, Franklin; C. T. Hendershot, Cannelston; D. J. Loring, Valparaiso; *Secretary*, F. C. Heath, Indianapolis; *Treasurer*, A. E. Bulson, Ft. Wayne. Edwin Walker, Evansville; W. N. Wishard, Indianapolis; D. C. Peyton, Jeffersonville, and C. A. Daugherty, South Bend, were selected delegates to the convention of the American Medical Association, at Atlantic City, in June. The State association will meet next year at West Baden. A resolution was adopted requesting the State Board of Medical Registration to refuse the demands of various literary institutions of the State that they be permitted to establish a two-year pre-medical course, to be recognized as that much of the regular four-years' college course demanded for the Bachelor of Science degree.

Kentucky State Medical Association.—The Kentucky State Medical Association closed its convention May 20 with the election of the following named officers: *President*, F. H. Clarke, Lexington; *Vice-Presidents*, L. L. Robinson, Middlesboro; H. S. Cooke, Wayne County, and Buckner Littlepage, Powell County; *Secretary*, James B. Bullit, Louisville; *Treasurer*, W. B. McClure, Lexington; *Orator in Surgery*, Louis Frank, Louisville; *Orator in Medicine*, J. A. McClymonds, Lexington; *Delegates to the American Medical Association*, J. H. McCormick, Bowling Green, and A. D. Price, Harrodsburg; *Delegate to Mississippi Valley Medical Association*, J. H. Stucky, Louisville. The only change made in the list of councillors was in the election of J. S. Locke of Knox County to succeed B. F. Herndon.

Ohio State Medical Association.—The association elected officers on May 20 as follows: *President*, Dr. S. S. Halderman, Portsmouth; *Vice-President*, Dr. J. S. Deemy, Bellefontaine; Dr. W. E. Morris, Lisbon, and Dr. H. H. McCullough, Mansfield; *Secretary*, Frank Wilders, Columbus; *Councillors*, First and Sixth Districts, Dr. Brooks F. Beebe, Cincinnati, and Dr. T. Clark Miller, Massillon; *Delegates to the American Medical Association Convention*, Dr. John P. Sawyer, Cleveland; Dr. J. F. Marchand, Canton, and Dr. Thos. Hubbard, Toledo.

State Hospital Changes.—At a meeting of the New York State Commission in Lunacy held May 21, the following transfers of superintendents were ordered to take effect June 1, 1904: Dr. O. M. Dewing, from the Long Island State Hospital, Kings Park, to the Long Island State Hospital, Flatbush; Dr. W. A. Macy, from the Willard State Hospital to the Long Island State Hospital, Kings Park, and Dr. R. M. Elliott, from the Long Island State Hospital, Flatbush, to the Willard State Hospital.

Officers of the Louisiana State Medical Society.—At the twenty-fifth annual session of the Louisiana State Medical Society, held at New Orleans May 10, 11, and 12, the following officers were elected to serve until May, 1905: *President*, Dr. Charles Chassaignac, New Orleans; *First Vice-President*, Dr. Oscar Dowling, Shreveport; *Second Vice-President*, Dr. L. C. Tarleton, Marksville; *Third Vice-President*, Dr. J. F. Buquoi, Colomb; *Secretary*, Dr. Isaac Ivan Lemann, New Orleans; *Treasurer*, Dr. M. H. McGuire, New Orleans. *Councillors:* A councillor was elected for each of the seven congressional districts, as follows: First, Dr. P. E. Archinard, New Orleans; Second, Dr. A.G. Friedrichs, New Orleans; Third, Dr. J. J. Ayo, Bowie; Fourth, Dr. N. K. Vance, Shreveport; Fifth, Dr. S. L. Williams, Oak Ridge; Sixth, Dr. C. M. Sitman, Greensburg; Seventh, Dr. C. A. Gardiner, Sunset. *Delegates to the American Medical Association:* Until 1905, Dr. W. G. Owen, White Castle; Alternate, Dr. A. F. Barrow, St. Francisville. Until 1906, Dr. Wm. M. Perkins, New Orleans: Alternate, Dr. J. B. Elliott, Jr., New Orleans.

Commencement of Medical Department of University of Cincinnati.—The annual commencement of the Ohio Medical College was held at the university auditorium May 25 at 3 P.M. Forty-six were graduated.

Jefferson Medical College.—The following clinical professors have been elected to full chairs with seats in the faculty: Dr. Howard Forde Hansell, ophthalmology; Dr. W. Joseph Hearn, surgery; Dr. Henry W. Stelwagon, dermatology; Dr. H. Augustus Wilson, orthopedic surgery; Dr. Edwin E. Graham, pediatrics; Dr. Orville Horwitz, genitourinary surgery; Dr. S. MacCuen Smith, otology; Dr. D. Braden Kyle, laryngology; Dr. Solomon Solis-Cohen, medicine. Dr. John H. Gibbon has been elected Associate Professor of Surgery; Dr. Randle C. Rosenberger, Assistant Professor of Bacteriology; Dr. Aller G. Ellis, Associate in Pathology.

Dr. Stanley Zinke of West Eighth street, Cincinnati, former city hospital interne, has successfully passed an examination to enter the medical department of the United States Army. He will enter the service with the rank of first lieutenant.

State Hospital Officials to Meet.—An interesting program has been prepared for the meeting of Ohio State Hospital officials to take place on June 21 at Longview Asylum, Cincinnati, under the presidency of Dr. Henry A. Tobey.

"Elks' Medical Relief Corps" is the name of an organization just perfected to attend to the physical ills of the Elks during the reunion next July in Cincinnati. Health Officer Davis has been elected chairman, and Dr. Otis, secretary, with the following members: Drs. Walker, Corboy, Wilson, Haerr, Wendel, Maloney, Bebe, and Musecamp. Others are expected to join. As the reunion is to be held during the most heated part of the year, and as men are somewhat careless on such occasions, it is anticipated that there will be more or less illness, and the design of the corps is to meet it. There will be a number of medical relief stations established, and an ambulance corps formed, the city being divided into districts for the purpose.

Illinois State Medical Society.—The fifty-fourth annual meeting was held at Bloomington, May 17, 18, and 19, 1904, under the presidency of Dr. Carl E. Black of Jacksonville. The scientific work was divided into two sections, medical and surgical. In both sections over sixty papers were read and discussed. There were symposia on tuberculosis, eclampsia, and carcinoma. The meeting was well attended. The following officers were elected for the ensuing year: *President*, Dr. Wm. E. Quine, Chicago; *Vice-Presidents*, Dr. H. C. Mitchell, Carbondale, and Dr. J. F. Percy, Galesburg; *Secretary*, Dr. E. W. Weis, Ottawa; *Treasurer*, Dr. Everett J. Brown, Decatur. Rock Island was selected as the place for holding the next annual meeting.

The Graduating Exercises for Nurses were held at the College of Physicans and Surgeons, Chicago, May 18, when twelve nurses were given diplomas, they having completed the three years' course of instruction given at the West Side Hospital.

Plague Bacilli Loose.—A London doctor, on his way home from India, is reported to have lost a number of test-tube cultures of plague bacilli somewhere between St. Paul and Chicago. The collection was made during a course of three years' study on the west coast of India.

American Laryngological, Rhinological, and Otological Society.—The tenth annual meeting of this society will be held in the Auditorium Hotel, Chicago, on May 30 and 31, and June 1, under the presidency of Dr. Nooval H. Pierce of Chicago. The secretary is Dr. Wendell C. Phillips, 40 West Forty-seventh Street, New York City. The program contains the titles of thirty-three papers and discussions. On the evening of the first day the president will entertain the fellows of the society at a reception, and the annual dinner will take place on the second evening.

National Association for the Study and Prevention of Tuberculosis.—The first meeting of this recently founded society will be held in the Public School Building, Atlantic City, N. J., on Monday evening, June 6, at 8 o'clock. A draft of a constitution and by-laws, drawn up by the committee on organization will be submitted for adoption at this meeting. Those intending to be present are requested to notify the secretary, Dr. H. B. Jacobs, 11 Mt. Vernon place, West, Baltimore, Md.

Maine Medical Association.—The fifty-second annual meeting of this society will be held in the Common Council Chamber of the City Hall, Portland, on June 1, 2, and 3, under the presidency of Dr. Augustus S. Thayer of Portland. The corresponding secretary is Dr. A. H. Sturtevant of Augusta. The annual dinner will be given on the afternoon of June 2 at 4 o'clock, and at 8 o'clock the evening the annual oration on "Anomalies of Thyroid Secretion" will be delivered by Dr. Frederick E. Shattuck of Boston.

Obituary Notes.—Dr. CHARLES HARRISON CRAWORD of Chicago died at his residence in that city i April 28. He was a graduate of the Albany Medal College in the class of 1881.

Dr. THOMAS J. FITZMAURICE of Paterson, N. J., ed on May 20 of disease of the liver. He was a aduate of the Bellevue Hospital Medical College this city in the class of 1891. He was elected derman about two years ago.

Dr. MERRITT H. CASH VAIL of Vailsburg, Essex ., N. J., died a few days ago at Long Beach, Cal. e was born in Glenwood, Sussex Co., N. J., seventyre years ago. He studied medicine with his uncle, r. Cash, obtaining his degree from the Castleton, t., Medical College in 1851, and then started in actice in Susquehanna, Pa. He went to Newark 1860 and practised there for a time. During the vil War he went to the front with the First New rsey Regiment of Volunteers. After the war he nducted the *Newark Morning Register* for ten years d later owned a weekly newspaper called the *ewark Item*. During his residence in Newark e represented the Second Ward on the Board of ducation. He was appointed County Superinndent in 1891. He afterward removed to South range, and founded the town of Vailsburg.

Dr. FRANK P. BLAIR of Allegany, N. Y., died on lay 21 of cancer, at the age of sixty-one years. le was a graduate of the Albany Medical College i the class of 1877.

Dr. J. ELWOOD PETERS died of apoplexy at Jenintown, Pa., on May 16, at the age of forty-nine ears. He was graduated from Hahnemann Medical ollege, Philadelphia, in the class of 1875.

Dr. ALVIN M. WOODWARD died at his home in his city on May 20, at the age of sixty-eight years. le was born at Dresden Mills, Me., and studied nedicine at Bowdoin College, later going to the Homœopathic Medical School in New York, where e was graduated in 1862. For thirty years he was ttending physician at the Protestant Orphan sylum in this city.

The Vital Importance of Detection and Relief of Eye-train.—Ambrose L. Ranney presents a comprehensive eries of conclusions and deductions, some of which are as ollows: Eye-strain can be a potent factor in disturbing he normal development of both mind and body and in ausing and perpetuating physical ills. Near-sightedness, hen uncomplicated, causes little or no eye-strain. An mperfect centering of a strong myopic glass to the pupils nay create great nervous disturbance, however, because f prismatic effects. Far-sightedness and astigmatism hould be recognized early in life and corrected by glasses. Both cause an unnatural expenditure of nervous force in proportion to the extent of the defect. Mal-adjustment f the eye muscles may exist as an independent deformity. t is a most prolific cause of physical and mental ills. Imperfect mental or physical development is very apt to e associated with some type of eye-strain. No child hould ever be allowed to begin its education without preliminary testing of the eyes and also of the eye muscles. The full amount of mal-adjustment of the eye muscles is not usually disclosed because sufferers of this class unconsciously acquire "tricks of adjustment." A very large proportion of eye defects is congenital. Eye-strain predisposes to the development of cataract and other eye diseases. The writer believes that many inmates of institutions for the feeble-minded, insane hospitals, and epileptic colonies, owe to eye-strain their confinement or social ostracism. This statement is based upon carefully collected clinical data. Legislative enactment should compel an eye examination of every child before it enters the public schools.—*New England Medical Monthly*. February, 1904.

OUR LONDON LETTER.

(From Our Special Correspondent.)

MEASLES IN SCHOOLS—CANCER—REPORT OF THE RESEARCH FUND — RADIUM, MR. PLIMMER'S VIEW—MIDDLESEX HOSPITAL DINNER—A CANCER WARD.

LONDON, April 5, 1904.

No one doubts the influence of schools in the spread of measles, and most of us agree that during our epidemic, children who have not suffered from it, should not attend. Dr. Newsholme, the energetic M. O. S. of Brighton goes further. He would exclude the infant classes and close infant schools compulsorily. They would certainly be better away from crowded school-rooms. If we desired to spread an infectious disease of children could we take a surer method than to crowd these classes into ill-ventilated rooms? Mere babies from three to six are really learning nothing *pace* the educationist's craze. The schools are popular enough for these babies. Yes, the mothers are thus relieved of care, and the teachers are enabled through them to secure a larger government grant, and so the poor mites are deprived of play and exposed to concentrated infection. Then those who favor the system hold up their hands in horror when told that 75 per cent. of the cases of measles occur among these infant classes with about 90 to 95 per cent. of the deaths. If those infants were excluded their natural protectors would have the care of them, about 14 per cent. would be added to the school accommodation of the country and a quarter of a million of pound sterling would be saved from the educational tax which is increasing so rapidly that a reaction is likely to set in against the extravagance of the self-styled "educationists."

The first report on the investigations of the Cancer Research Fund, under the direction of the two Royal colleges is now out and contains three papers, recording the work done by Drs. Bashford and Murray. In the first paper the zoological distribution of the disease is considered. Growths with the histological characteristics of cancer have been obtained from domestic animals, captive wild animals and the same in their wild surroundings. These observations confirm those of previous investigations as to the wide distribution of cancer among vertebrates and show how slight, if any, must be the influence of diet, habitation, and other conditions.

In the next section, the transmissibility of malignant growths from one animal to another is considered. The success announced by Jensen and Borrel in transplanting cancer in mice from one animal to another was further tested in the laboratory with material supplied by Professor Jensen. With this material, 259 inoculations were made. The result was successful in 25 to 30 per cent., and confirmed Jensen's statement that the development of the tumors arose from the actual cells inoculated. In successful transplantations the parenchyma of the growth preserves the same characters. The rate of growth and the proportion of stroma is subject to variation. The success is prevented by exposing the tissue to a temperature of 37° C. for twenty-four hours. Breaking it down in a mortar does the same.

The third section is devoted to the comparative cytological characters of malignant growths. Here I notice that the heterotype mitosis described by Farmer, Moore, and Walker, and which I reported to you at the time, is confirmed by the work in the Cancer Research Laboratory. The number of cells showing this mitosis varies in different tumors and seems to have no relation to the degree of malignancy; the mitoses in the growing margin are uniformly of the somatic type, and where rapid degeneration is going on, are sometimes difficult to find. This militates strongly against their value as an aid to diagnosis.

The negative results of transplantation of tissue of the testis or ovary also militates against the view of Farmer, Moore, and Walker that the cancer process is a transformation of normal into reproductive tissue possessing malignant properties. Certain nuclear figures seen in some of the carcinomata examined are considered to support the idea that a sort of conjugation takes place in these cells; if so, a new cycle would thereby be started, and the independent growth of new malignant tumors explained. Whether such conjugation of the cells or nuclei of normal tissues occurs to start a cancer tissue is a matter for further investigation.

Mr. H. G. Plimmer's experiments with radium in cases of cancer is generally quoted as almost conclusive that the hopes generally excited are to be disappointed. He investigated seventeen cases of carcinoma, some of them in an advanced condition. One was a fungating mass secondary to epithelioma of the jaw. Another a sloughing epithelioma of the lip, the others mostly schirrus. The exposures varied in length of time but none were very

prolonged. One could scarcely expect a very great effect in the deeper parts from a brief exposure, and the results of these trials are particularly negative. Mr. Plimmer says, "It appears as if the emanations from radium can only act upon young and rapidly growing cells, and that older cells, especially if surounded by fibrous tissue, are less and less easily affected, and if there be an excess of fibrous tissue the cells are not at all affected." This agrees very well with the effect observed by Exner in a case of melanotic sarcoma and with Apolants' experiments on mice, and is, perhaps, the opinion most generally entertained at present.

The Lord Mayor presided at a dinner in aid of the Middlesex Hospital on Tuesday. About 170 guests were present and above £6,000 subscribed. Lord Sanhurst, the Chairman of the Weekly Board, mentioned the improvements lately made and said that the records of the institution from 1746 had been examined, giving statistics of six thousand cases of cancer which would, no doubt, be useful to investigators. The Lord Mayor said the hospital was established 150 years ago and opened the cancer ward twenty years afterward. You are aware how this ward has developed and that the Middlesex Cancer Research is being carried on under the best auspices.

DISINFECTION OF CAR CLOSETS.

To the Editor of the Medical Record:

Sir: My attention has lately been called to an interesting article by Dr. P. B. Barringer, in your issue of December 19, 1903. In discussing the etiology of typhoid fever, he alludes to an Unrecognized Source in the dissemination of fæces by railroad trains and suggests a retention closet. While hygienists must generally have seen the advisability of retention closets on trains and fresh-water boats, if their attention has been thus directed, so that the matter of priority is unimportant, I take the liberty to quote from an article published in the *Buffalo Medical and Surgical Journal* of October, 1892. During the summer and fall of 1892, there was considerable apprehension of an epidemic of cholera asiatica, and the health physicians were ordered to report on the sanitary conditions of their districts, with special reference to the conditions bearing on a possible epidemic of cholera. As my district included the principal station and considerable of the intramural tracks, railroad sanitation was considered in a separate paragraph. . . . "As railroads are the principal carriers of infection to inland towns, and as the main exit of the cholera spirillum is through the intestine, the closets in passenger cars should be kept locked inside the city limits. In fact, it would be better . . . to have a metal bucket fitted to the ordinary open cylinder of the car closet. A disinfectant could be kept in the bucket, which could be changed at certain stations and the disinfection completed."

A. L. Benedict, M.D.

Buffalo, N.Y., May 7, 1904.

Sulphur Baths.—P. Roethlisberger presents the results of his experiments with sulphur baths. He found that in the baths and for a considerable time afterward, the temperature of the rectum showed a marked diminution, whereas the external (axillary) temperature increased or remained stationary in baths varying from 88° to 100° F. In water of 100° to 100½° the heat of the rectum decidely rose, but dropped below normal after the baths. The number of the heart's pulsations were distinctively diminished in the baths at a temperature of 88° to 93½° F. This effect lasted for sometime. The number of pulsations increased in baths of 97° to 100½°. The blood pressure was very little lowered by the warmer baths, but was increased by the cooler ones. At the very commencement of all baths the number of respirations increased and remained more frequent in the warmer ones. In the cooler baths, the respirations became normal again, or even subnormal, this diminution continuing after the baths. As to nutrition, during and after bathing, there was a very marked increase of urea in proportion to the total nitrogen, showing diminution of the xanthin bases lessening of the acidity of the urine, a decrease of the total phosphates, and augmentation of the total sulphates. There was regular increase of hunger and thirst during bathing. After the cooler baths there was augmentation of muscular strength, and after the warm ones, a diminution of the same—*Journal of Balneology and Climatology.*

Progress of Medical Science.

The Boston Medical and Surgical Journal, May 19, 1904.

Enterostomy in Peritonitis.—Robert B. Greenough sums up the points covered in his paper as follows: The obstruction of the intestine in diffuse peritonitis is the result of a combination of causes. The most important cause is suspension or paralysis of peristalsis. Paralysis of peristalsis is due to inhibition, to toxic paralysis, and to the paralysis of distention. Mechanical causes, such as infiltration of the bowel wall and light adhesions in certain cases contribute to this paralysis. Pure mechanical obstruction due to adhesions is the result of chronic or local peritonitis of at least some days' duration. Enterostomy is indicated in addition to other operative measures in the graver forms of diffuse peritonitis. Its greatest advantage is the drainage of the gases and decomposing contents of the bowel and the relief of paralysis of peristalsis. By enterostomy the surgeon obtains direct control over the intestine for lavage and for the introduction of stimulants, nourishment, fluids and cathartics. For the relief of paralysis of peristalsis primary enterostomy is to be preferred to the secondary operation. Enterostomy is best performed by the use of the Mixter tube. The cæcum is the most satisfactory part of the bowel for a primary enterostomy, and the jejunum is to be avoided. Spontaneous closure of the fistula may be expected when the cæcum is opened, if the opening is kept below the level of the parietal peritoneum. By the systematic use of enterostomy in the graver forms of diffuse peritonitis the number of patients dying on the second, third and fourth days after operation is reduced. The symptoms of visible peristalsis and spasmodic pain in intestinal obstruction indicate a mechanical cause for the obstruction. The persistence of these symptoms, unrelieved by enemata and cathartics, is an indication for operation. Under these circumstances the cause of the obstruction should be removed if possible by operation. In advanced cases of obstruction of this form, enterostomy of the coil of intestine nearest above the obstruction should be done.

Journal of the American Medical Association, May 21, 1904.

The Apostoli Treatment.—G. Betton Massey summarizes the final results of this method of treatment in some cases of uterine fibroids. His conclusions are as follows: (1) A prolonged observation of cases of fibroid tumors of the uterus under the Apostoli treatment teaches that three-quarters of the cases subjected to this method will be practically cured, as attested by inquiries made from three to sixteen years after the cessation of treatment. (2) The cases that responded poorly, or not at all, to this treatment are not harmed by it, when properly applied, and heroic measures may then be adopted with the certainty that milder means are of no avail. (3) Hemorrhagic and interstitial fibroids are best adapted to the Apostoli treatment, while subperitoneal or degenerative fibroids and those complicated with pyosalpinx are least adapted to be relieved by it. (4) So far as the author's inquiries and circulars show, there have been but seven deaths among one hundred and ten patients during the sixteen years or less that they have been under his observation. It is an interesting fact, moreover, that but one of these deaths was due to the progress of the growth itself, proving the non-mortal character of this affection. Of the remaining six, one died long after treatment of an affection totally unconnected with the growth, one of septicæmia under electric treatment and four while under operation with the knife.

Serum-therapeutic Measures.—H. T. Rickets reviews the progress that has been made along the lines indicated. He notes that various salts even in nitrate quantities inhibit the action of this class of remedies, and suggests that susceptibility and resistance to infection may vary according to the saline elements in the blood at the time of exposure to infection. He believes that certain laws have been discovered in accordance with which certain immunity reactions occur. Some of our sero-therapeutic measures, especially vaccination and the antitoxin treatment of disease, justify a belief in these laws, but our failure in other directions shows that to these laws are attached certain corollaries about which we are still ignorant. We are not yet in a position to treat all threatened cases by vaccination of various kinds, but our immediate task is to seek for antitoxins for all the infectious diseases. As yet all our attempts to obtain from such bacteria as the typhoid bacillus, toxins, immunization with which will yield an antitoxic serum of value in combating the established infection, have failed. It may be that the desired result will come out of the attempts made to obtain an anti-typhoid preparation by grinding the bacillus at the temperature of liquified air. If we can attain success in the case of this particular malady, there

s reason to hope for a like happy result with other diseases.

The Use and Abuse of Hypnotics.—According to W. Blair Stewart, no plan of treating insomnia is rational hat does not seek for the underlying cause of the condition complained of. The insomnia of acute indigestion, ever, earache, toothache, outside noises calls for the rimary removal of the respective causes of these conditions and not for the routine administration of some avorite remedy. Mild massage, warm baths, and warm il-rubs at bed time will often render drugs unnecessary. o prescribe alcohol even in small quantities to induce leep is a dangerous procedure. There is always danger of abit-formation, and there comes a time when only a large uantity will induce sleep and this sleep is not restful. loreover, the next day there appear the toxic effects of he alcohol in the shape of nervousness, irritability, eadache, anorexia, and often delusions. All of the usual ypnotics are cardiac depressants and ought to be given ith the greatest caution. Perhaps the two safest are ional and sulfonal in that they offer the smallest amount f disagreeable after-effects. Thorough ventilation of the leeping room, hypnotic suggestion, and a cup of warm roth or milk on retiring often render any other measures nnecessary.

The Operative Treatment of Eclampsia.—C. S. Bacon ealizes that operation is often the only way by which to revent eclamptic seizures. Two methods come under onsideration, induction of labor and cæsarean section. or the former that method should be selected which ffers the least amount of disturbance to the patient. For n anæsthetic the author prefers ether to chloroform. o control convulsions simply, morphine is the preferable emedy. Purgation by croton oil, diaphoresis by hot packs, venesection from the arm, normal salt solutions nder the skin and oxygen all are adjuvants to the operative procedure adopted. Slow dilatation of the cervix is preferable, and we should dilate the cervix with a branch or olid dilator to admit one finger, rupture the membranes nd introduce a small Voorhees bag. Then ether should be withdrawn and the patient put back in bed. With careful control of symptoms and care for elimination the labor should be allowed to progress until the bag is expelled. Then if necessary the anæsthetic should be given again and another bag inserted, and again labor be allowed to proceed as before. Finally, after the cervix is well dilated, or after effacement is complete and more active dilatation is safe, more active measures may be taken to deliver the child.

Medical News, May 21, 1904.

Fracture of the Base of the Skull as a Cause of Epilepsy.—Charles T. Aldrich states that his search of the literature establishes the fact that epilepsy is an infrequent sequel of basal fracture. The cause of this infrequency is probably due to the fact that when the base is fractured, the contiguous brain structures are the ones most likely to suffer. These are not structures whose injury is liable to result in convulsive disease, and fractures of the base. When the lesions are severe, extending to the convexity, they usually result in death. The writer believes that cerebral injury wherever located may in after years result in epilepsy. He believes that fracture of the base will be far more liable to produce epilepsy than concussion alone. The writer then reports the history of a case. The patient, a man of thirty-two years, fractured the base of his skull at the age of eighteen. One year following the injury he had a "spell," in which he jerked and twitched, and was unconscious; this was undoubtedly an epileptic fit. Eleven years later he had another attack, in which he presented all of the classical characteristics of a major epileptic seizure. Since that time he has had other attacks. There is no aura. He appears to be irritable for several days preceding the epilepsy. During the seizure his eyes are turned to the right and upward. The face is also turned to the right with the chin over the right shoulder. The body is then twisted around. The clavic spasms are severe. After recovery from the attack he suffers only from general weakness and numbness, neither of which is localized.

The Classification and Symptomatology of Diseases of the Pancreas.—Charles G. Stockton first speaks of tumors of the pancreas. These occur as carcinomata of various forms, adenomata, tuberculosis, syphilis, and cysts. The so-called inflammatory diseases of the pancreas are next discussed. Two forms of distribution of the fibroid degeneration are now accepted: one, the ordinary interlobular type; the other, characterized by diffuse proliferation of the interacinar tissue which invades the islands of Langerhans and apparently constitutes the structural change upon which pancreatic diabetes depends. The writer does not think it satisfactory to attempt the explanation of acute pancreatic processes along the line of ordinary inflammation. In some instances an inflammatory reaction is evident, in others it is entirely lacking. The term necrosis seems more appropriate than inflammation in describing certain instances of acute disease of the pancreas. The presence of hemorrhage in these cases is most significant. The symptomatology of acute hemorrhagic pancreatitis and that of hemorrhage into the pancreas are very closely related. Hemorrhage may be the first recognized step in the necrotic process. In the onset there is intense pain in the lower part of the epigastrium, manifestations of shock, generally nausea and vomiting. These symptoms may continue for a few hours or days. The general appearance of the patient suggests a grave abdominal trouble. The bowels are usually somewhat sluggish. The symptoms are increased by movements of the body. Sometimes the patient sinks into stupor at the last. In suppurative pancreatitis or pancreatitic abscess, there is considerable variation of the symptoms in different cases. In a proportion of cases there is both purulent and hemorrhagic pancreatitis in the same case, producing a group of symptoms that include those which relate to hemorrhage, necrosis, and suppuration. Leucocytosis is to be expected in suppurative cases, but is inconspicuous or absent in those of other types. The fat necrosis of Balser occurs in most but not all acute processes of the pancreas. A number of questions concerning the diseases of this organ yet remain to be elucidated.

New York Medical Journal, May 21, 1904.

A Case of Diabetes Mellitus; Gangrene of the Foot; Operation; Recovery.—The patient of E. P. Stone was an army officer of sixty-five years. The history of diabetes dated back over twenty years, presenting the usual features. In the eighteenth year of the disease gangrene appeared in the right great toe and gradually extended up to the ankle,where a line of demarcation formed. It was the dry, mummifying form of the disease and was comparatively painless. During this time the condition of the urine was gradually improving and finally the absence of sugar was reported. Albumin—formerly present in fair amount—was reduced to little more than a trace, but hyaline and granular casts persisted. The condition of the foot had meantime become a menace to life and amputation, under chloroform anæsthesia, was performed at the junction of the middle and upper thirds. Recovery was uneventful. Three years later the patient was a in very comfortable condition. The sugar had not returned though albumin was present in larger percentage than before the operation, together with hyaline, granular, and occasional epithelial casts.

American Medicine, May 21, 1904.

A Case of Splenomyelogenous Leukæmia Showing Marked Improvement under the Use of the Röntgen Ray.—Charles H. Weber gives an interesting account of this case. The patient, a widow of fifty-three, has now been under observation for a period of less than six months. During this time there has been a progressive improvement in her general condition, symptoms, and blood. For the last five months she has received no medication, only the Röntgen ray. There have been no fluctuations in the blood counts, as exhibited in some cases. The myelocytes have gradually decreased, both relatively and absolutely. At the last examination they had entirely disappeared. At present the blood is normal practically, and if the patient were to come under examination now for the first time, a proper diagnosis would be impossible. The patient feels as well as ever. The case is not reported as a recovery, but it would seem to offer evidence that the Röntgen ray has been of therapeutic value in this condition. Whether in the Röntgen ray there has been found a method which gives permanent relief, time alone will determine.

The Treatment of Pneumonia.—R. S. Thornton declares that pneumonia is a disease which will not submit to cast-iron rules of treatment. It presents a great variety of types. But there are a few indications that are important to be observed in all cases. The chief one of these is rest—both general and local. This means a firm bed. It means the use of the bed-pan, the urine jar, the feeding cup. Every muscular movement that can be avoided, must be avoided. The heart must suffer no unnecessary exertion. Rest means especially that there shall be no talking and no visitors. The temperature of the room must be as equable as possible, at 65° to 70°. The atmosphere should be moistened, especially in winter. As to poultices, they give relief and are welcomed by the patient. But when consolidation has taken place the poultice should be discarded. A smart mustard plaster, the cotton jacket and the hot-water bag all have their use. It is most important to keep the bowels and kidneys acting freely. Sufficient water must be given. An initial purge is indicated—a dose of calomel, or better, a saline laxative.

The writer then discusses the uses of drugs. Digitalin and strychnine are of special value near and after the time of crisis. He has abandoned the use of alcohol altogether. He emphasizes the value of creosote. It is important that the creosote or creosote carbonate should be continued throughout convalescence. The probable explanation of its action is that of an internal antiseptic.

Ulcerative Endocarditis: Report of a Case.—William H. Morrison reports this case that came under his care. The patient, a lad of twelve, had been perfectly well up to the age of six, at which time he presented symptoms indicating the presence of scarlet fever, sore throat, and eruption. Later, he suffered from an attack of nephritis. He was treated for this condition for six or seven months, after which he seemed fairly well with the exception that any extra exertion, as running, led to violent action of the heart, dyspnœa, dry cough, and cyanosis. About five years later he had another illness which was diagnosed as typhoid fever. Two months later he was placed under the writer's care. There was entire absence of symptoms and signs, with the exception of remittent fever, rapid pulse, mitral systolic murmur, and enlargement of the liver and spleen. A careful temperature record was kept for weeks and showed an exceedingly irregular and remittent fever. As a rule the highest point was reached at noon. Considering the history of old cardiac disease, the presence of a continuous, irregular temperature and the absence of the evidences of local disease with the exception of those referable to the mitral valve, a diagnosis of ulcerative endocarditis seemed to be warranted. The prognosis was unfavorable. About six weeks before death there was a sudden attack of severe pain in the right iliac region associated with a fall of the temperature to 97°. This was relieved by a small hypodermic injection of morphia. Two weeks before death there was suppression of urine, with œdema of the face. The urine contained a trace of albumin and a few blood corpuscles. Ten days before death there occurred an attack of syncope. Petechias made their appearance for the first time one week before death. The boy grew steadily weaker and died of exhaustion. Autopsy showed extensive disease of both leaflets of the mitral valve, the entire auricular surface of the valve being covered to the depth of half an inch with friable vegetations. No bacteriologic study was made.

The Lancet, May 14, 1904.

Fasting in Therapeutics.—J. Haddon gives an account of the effects of fasting in the case of a man of sixty-five years who had been a heavy eater and drinker all his life. A scaffold had fallen on him, and when first seen by the author seven years later he walked only with a cane, could not sleep from coughing and spitting, urinated every hour, and could hardly turn in bed from a stabbing pain in the side. He was put on a little fruit twice daily. In five days he lost ten pounds in weight and could dress himself. All his troublesome symptoms left him. He was able to sleep all night, and in a few months was able to perform quite laborious exercise. His pulse at first irregular and intermittent, gradually improved and became fairly regular. He felt neither hungry nor thirsty on the fruit diet.

A Chinese Remedy for Hydrophobia.—V. G. Thorpe finds that a remedy much in vogue in China for cases of hydrophobia is probably nothing more or less than the ordinary strychnine, though in the hands of the natives narcotic and sudorific effects seem to have followed its use. A reference to these effects is found by the author in an old edition (1786) of Chambers' Encyclopædia, although there is no allusion to its employment in the disease in question. Some of the symptoms of hydrophobia bear a certain resemblance to those of poisoning by strychinine, and it would, therefore, almost appear as though the principle of *similia similibus curantur* has been applied by the Chinese in this case. There is no doubt that in regard to other remedies they have a firm belief in this doctrine.

The Relation of the Pancreas to Diabetes and the Question of the Transplantation of that Gland as a Remedy for the Disease.—J. W. Allan calls attention to the following facts: (1) It is well-known that total extirpation of the pancreas induces diabetes. (2) If only a portion of the pancreas is left—even the splenic end—no diabetes occurs. (3) If pancreas is transplanted into an animal before its own pancreas is cut out no diabetes takes place. If the graft is removed diabetes occurs. (4) From (2) and (3) it is evident that the prevention of glycosuria is not due to the ordinary secretion of the pancreas, which flows into the duodenum by the duct of Wirsung. (5) It is reasonable to assume that the organ produces an internal sugar-destroying secretion, and that the portion of gland left (2), or the transplanted gland (3), has the power of forming that sugar-destroying secretion or juice. (6) From the foregoing it might, therefore, be hoped that by transplantation of pancreas a case of diabetes might be cured or relieved. (7) Again, turning to the pathological aspect of the question, we find that disease of the pancreas is frequently associated with diabetes, as is shown *post-mortem*. This is well known and it is, perhaps, unnecessary to cite particular instances. (8) But it must be admitted that there are many cases of diabetes in which no disease of the pancreas is detected. How are we to explain these cases? In the first place, a naked-eye examination may fail to reveal changes in the organ and it may be hastily pronounced "normal" or "healthy." But the real question is, has the gland been subjected to a careful microscopic examination by a skilled observer and does that examination show the islands of Langerhans to be in a health condition? for in those islands the sugar-destroying ferment, the "internal secretion," is produced. From the results of thymoid transplantation in myxœdema, Allan believes that that of the pancreas in diabetes is reasonable and justifiable. Internal administration of pancreatic preparations has been disappointing. He says that if he had a case of diabetes which did not respond to dietetic or drug treatment, and was drifting within the range of diabetic coma, he should be willing to assume the responsibility of advising transplantation of pancreas on the following conditions: (1) That after full and honest explanation of pros and cons the patient requested that the operation shall be performed; (2) that the patient was not suffering from acetonuria at the time; and (3) that a sheep should be killed close to, or in, the place of operation and its pancreas directly conveyed to the body of the patient.

British Medical Journal, May 14, 1904.

The Prevention of Bubonic Plague.—C. Marsh-Beadnell calls attention to the fact that the means of entrance of the plague microorganism or its spore is most often by a solution of continuity of the skin or mucous membrane. This is usually situated in the foot amongst non-Europeans. The writer thinks it would be a good plan to compel all "colored" people resident within or in the immediate neighborhood of plague-infected areas, to wear an adequate protective covering to their feet. He thinks that if this suggestion were enforced, a marked diminution in the bubonic plague-rate would ensue.

The Occurrence of Primary Tuberculous Infection of the Intestinal Tract in Children; the Results of 5,142 Consecutive Necropsies.—William Hunter has made a careful study of this subject. He believes that primary tuberculosis of the intestine is rare in children under five years of age. He believes, too, that tuberculosis of the mesenteric glands is also rare. These necropsies were held during the years 1902 and 1903 at the public mortuary in Hong-kong. The number of children under five years old comprised about 35 per cent. The bodies came from all parts of Hong-kong and the adjoining newly acquired territory. The writer believes that the results obtained amongst a native population where tuberculosis in all its forms is rife, and the conditions of life extremely favorable for the dissemination of the disease, point to the alimentary canal as a rare avenue through which infection in tuberculosis is conveyed in childhood.

Abdominal Pain in Acute Rheumatism.—S. Vere Pearson, in describing this pain, says that it is nearly always situated about the upper half of the abdomen. It is not a superficial pain, but is invariably said to be "inside." Yet it does not go through to the back nor travel round the trunk. It is of short duration, but recurs. It is not associated with nausea or vomiting. It comes on independently of food. Any explanation of its causation must at present rest upon mere speculation. The treatment of this symptom is that of acute rheumatism. When occurring in children, especially if the symptoms are only moderately severe, this is often quite difficult. Sodium salicylate will often alleviate the pain. But when it is severe its cure as a rule is only affected by putting the patient to bed and giving full antirheumatic treatment. Much patience is required in investigating such symptoms in a child.

Remarks on the Infective Nature of Rheumatic Fever, Illustrated by the Study of a Fatal Case.—F. J. Poynton reports the twenty-fifth fatal case that he has investigated. After death the bacteriological results from the cultures were as follows: Pure cultures of the diplococcus were found in the tubes inoculated from the mitral valve, the spleen, and the kidney. The culture from the lung was not pure, but the diplococcus was present among other microorganisms. The tubes containing the pericardial fluid and the blood gave negative results. But these microorganisms, when they grow in the body, grow best in the local lesions, and although they are often present

n the blood they do not thrive in it. Neither are they asily found in recent exudations, for they lie in the novial tissues, and not in the pericardiac exudations. o reach these fluids they must destroy the phagocytic ndothelia that line the synovial membrane and peri-ardium, and the reason why the microorganisms are eposited in the tissues and not at first in the exudation, clearly because they are carried in the blood stream, nd when they escape they will find themselves in the nnective tissues around the blood capillaries. It is ot to be expected that in a slight attack of rheumatic ver, either examination of the blood or of the synovial udation will often result in success. In speaking of the ractical applications of the infective view of rheumatic ver, the writer mentions the following facts: The ex-tence of a true rheumatic bronchopneumonia and a eumatic pleurisy, the existence of a true renal rheuma-sm; the existence of a true rheumatic peritonitis. He ids that simple and malignant endocarditis can be ages in the same process. So if rheumatic endocarditis infective it can be both simple and malignant in type. nte-mortem thrombosis may occur in the heart in eumatic fever without any severe valvular damage. ccurate knowledge can now be obtained upon the pidity of the formation of vegetations and upon their tual structure. The myocardial changes in rheuma-sm are absolutely proved by experiment, for they can e produced by this microorganism. The author gives an lustration of a section taken through a vegetation on the itral valve showing numerous diplococci and chains in he necrotic tissue.

Deutsche medizinische Wochenschrift, May 5, 1904.

Hæmaturia as a Sign of Scurvy.—E. Neter calls atten-ion to the fact that a hæmaturia may be the only evident utward sign of the presence of Barlow's disease. He eports a typical case in a well-developed infant of eight nonths, who had been fed during the previous four nonths exclusively with malted foods. The child did not eem quite well, but the only result of the examination as the finding of blood in the urine. The diagnosis of curvy was made by exclusion and the child was put on a iet of raw milk. In eight days after beginning treat-ent the baby was better and no more blood was found n the stools. The author suggests that in every child n which hæmaturia is present, and all other bladder or idney troubles can be excluded, the presence of scurvy hould be suspected. In doubtful cases, appropriate ntiscorbutic treatment will always aid in confirming he diagnosis.

A New Serum for the Cure of Dysentery.—L. Rosenthal as made some successful experiments with a curative erum obtained from horses. If 0.5 c.c. of this serum ere injected into a guinea-pig the day after infection ad occurred, the animal would be saved, whereas the ontrol animal perished within twenty-four hours. Anti-oxic properties are also attributed to the serum. He eports having used the serum in 157 cases, about 20-40 c.c. eing given in the average case. The only sequelæ ere occasional erythema or urticaria. The mortality ate in this series of cases was about 4½ per cent., while he prevalent rate at the Moscow Hospital was between 12 per cent. and 17 per cent. The author claims that he serum has a favorable effect on all the subjective nd objective symptoms. Pain and tenesmus lessens within twenty-four hours, blood disappears from the tools, the duration of the disease is shortened, and the hronic form seldom comes on, and finally the death rate s reduced over one-half. Recovery takes place within ne to two days, if the serum is administered within the irst three days after the disease has infected the patient.

A New Distomum Found in Man.—M. Askanazy re-orted some three years ago that a parasite, commonly ound in cats and dogs in certain European countries, had in two instances been demonstrated in man. The parasite is known as Distomum felineum. The same uthor has now made some further studies on the etiology nd pathology of the disease, which raises several inter-esting questions. One of the cases which he reported had been dagnosed as tumor of the liver together with ob-struction of the inferior vena cava. The autopsy showed an extensive carcinoma of the liver, and within the biliary passages there was found a great number of dis-toma and their eggs in various stages of development. As this and another case also presented evidences of in-fection by tapeworm, the author investigated the stools of a large number of persons afflicted with this parasite. Out of fifteen, five also were infected with the Distomum felineum. The fact that carcinoma of the biliary pas-sages was present in a number of other cases in which the distomum was found at the same time, inclines the author to the belief that the epithelial proliferation due to their presence may afford a predisposing cause for the produc-tion of cancer. The parasite is very prevalent in cats and dogs in sea-port towns, and efforts to find the source of the infection resulted in the discovery that most of these animals had been consuming quantities of raw fish. The roach (Leuciscus rutilis) seemed to be the chief source of infection, and animals fed exclusively with this species soon showed the presence of the parasitic worm. It is also to be noted that one of the patients stated that he had been accustomed to eating raw fish. Further ex-periments are now under way for the purpose of deter-mining whether it is possible to produce cancer in dogs by feeding them with infected fish. In the intermediate stage the parasite has not yet been demonstrated in the fish, and the complete cycle of development therefore still remains to be worked out.

Berliner klinische Wochenschrift, May 2, 1904.

Facial Anomalies and Their Effects.—V. Babes calls at-tention to a class of cases in which a primary facial anomaly may be accompanied by marked anomalies in the ex-tremities. He has collected a number of these in which the cranial malformations were principally marked by early ossification and sclerosis of the base of the skull. All four extremities are usually involved, although those in the upper are most clearly marked. The changes may be divided into three classes: (1) A toe or finger may be absent, or there may be general shortening of the entire limb; (2) the number of fingers or toes may be increased, and there may be an increase in the size of the limb; and (3) the change may include both excess and defect, such as an increase in the number of metatarsal bones, amalgamation of either fingers or toes, and an increase or decrease in the length of the limbs. A remarkable fact about these phenomena is the symmetrical arrange-ment of these deformities, as well as their resemblance to certain animal groups—the arthrodactylates, the perissdactylates, and the bidactylates. From the cases which he has studied he concludes that there is a region in the base of the skull which stands in close relation to the development of the extremities. In other words, we must assume the existence of a center in this region which determines the normal development, and any change in the shape or character of the former will have as a result an abnormal growth of the limbs. Further studies along these lines may serve as an aid in clearing up our knowledge of some of the processes which underlie the differentiation of the various races and classes of animals.

The Significance of Blood Traces in the Fæces.—Joachim has made an extended series of observations of the stools of a large number of patients suffering from various diseases in which there might have been hemorrhage in some part of the intestinal canal. The guaiac and aloin tests after the method of Rössel were both employed. The test was always negative in those cases in which the presence of blood in the stools could not have been ex-plained. But even the coming on of a slight epistaxis produced a positive result. After a hæmoptysis, however, this was rare, probably because in the latter case the sputum is not usually swallowed. Among malignant tumors of the alimentary canal, the tests were positive in every case with the exception of a carcinoma of the œsophagus. The hemorrhage was regular but weak, whereas in gastric ulce the bleeding was more profuse and irregular and sometimes was entirely absent from the stools. Much less tendency to hemorrhage was shown by other ulcerative processes. In cases of tuber-culosis of the small intestine, traces of blood were never found in the stools. In typhoid fever it was possible to de-tect evidences of blood by these tests before any gross ap-pearances were present, and this means of diagnosing pre-monitory hemorrhages may prove of value. In ordinary gastric catarrhs the test was negative, also in gastro-ptosis and in all lesions immediately surrounding the tract, appendicitis, subphrenic abscess, etc. In the presence of marked venous stasis, as with cardiac disease accompanied by compensatory disturbances, it was al-ways possible to demonstrate blood in the stools. This disappeared as soon as the stasis was relieved. In catar-rhal jaundice the tests was always positive, but in cases of cholelithiasis they were negative. When a secondary carcinoma of the liver was present, blood could always be demonstrated in the stools. Although these tests have undoubted clinical value, their diagnostic importance is not so great, on account of the large number of diseases of the intestinal tract in which hemorrhages can be demonstrated. The information secured by these tests may prove of value, however, in tracing the progress of a disease, such as gastric ulcer, and in this manner judging the effect of the various methods of treatment. To avoid the possibility of error, the author recommends that both tests be employed in all cases, as one then acts as control on the other. Other factors which must be borne in mind in drawing final conclusions are, the possibility of

an admixture of menstrual blood or of that from bleeding hemorrhoids, gums, or nose, and blood-stained sputum which may have been swallowed. When food containing blood has been eaten, such as raw meat, blood sausage, etc., the test may also result positively.

Münchener medizinische Wochenschrift, May 3, 1904.

Effect of Alternating Current Baths on the Heart.—Büddingen and Geissler have studied the value of these baths in a number of cases and claim that the results in all cases were favorable. The subjective symptoms show immediate improvement; this includes the feeling of pressure in the cardiac region, palpitation, the dyspnœa, etc. Among the changes in the objective signs, the most noticeable is the diminution in the area of cardiac dulness. The irregular heart action also improved and the pulse became less frequent and strong. The authors, although recognizing the value of these baths, insist that other therapeutic measures must not be neglected. Certain precautions must be observed, as not all cases are suitable for this treatment. As the contractile elements in the muscular system are stimulated, the heart is called upon for an exertion. A heart which therefore has no reserve strength, or very little, needs rest rather than procedures of this kind. Contraindications are a weak heart or advanced arterial sclerosis.

Effect of the X-rays on the Internal Organs.—H. Heinecke, in some experiments made about a year ago, found that small animals exposed to the rays for a number of hours, died in from seven to fourteen days. The spleen showed an excessive increase in the pigment, a disappearance of the follicles, and a destruction of the splenic pulp. More recently he extended his experiments and exposed a larger number of animals of about the same size He then found that it was possible to separate entirely the processes in the follicles from those taking place in the other parts of the spleen. The former started a few hours after beginning the radiations and were completed in twenty-four hours. The nuclei of the lymphocytes in the follicles disintegrate within a few hours and the remnants are taken up by the phagocytes, which shortly disappear from the spleen. This results in an almost complete destruction of the follicle. Analogous processes are also found to take place in all other lymphoid structures of the body. In the marrow similar processes occur. When larger animals, such as the dog, were employed for the experiments, the same results were obtained, except that the time was slightly prolonged. It was determined that the minimum length of time required to bring about these changes was fifteen minutes in rabbits or a moderate size dog. For these short exposures the amount of destruction is limited and repair can undoubtedly take place. These experiments show that there are cells in the body which react to the rays much more quickly and delicately than the cells of the epidermis. The author believes that similar effects take place in man, and that the lymphoid structures are affected without there being any marked reaction in the skin. He therefore claims that a therapeutic application may be made of this principle in treating certain diseases of the lymphatic system—leukæmia, pseudo-leukæmia, malignant lymphomata and lympho-sarcomata. It may also prove of value when disturbances are due to an abnormally large thymus. He has not made any use of this method himself, but in a foot-note refers to cases of leukæmia thus treated by American surgeons.

French and Italian Journals.

Pernicious Malarial Infection.—Agenore Zeri contributes the histories of four cases of pernicious malarial fever contracted in the Roman Campagna. All four were confirmed as true malarial cases by the examination of the blood and the finding of the parasites, though few in number. No organisms were found with central masses of pigment. It would be a grave error in such cases to fail to make the diagnosis of malarial fever on account of the scarcity of organisms, and one that would be fatal to the patient. In one of the author's cases the patient had previously had a malarial attack with hemorrhage from the stomach, vomiting, and severe abdominal pain. In the pernicious attack he was also affected by severe hemorrhage and vomiting. In another case in which there were severe cerebral symptoms there had previously been an affection of the middle ear. Bacelli has stated that the individual affected by any other disease or weakness finds it more difficult to resist pernicious malarial infection. Headache, vomiting, and vertigo are usual symptoms in these cases. The vertigo is not due to the quinine given, for heavy doses of quinine cut short the fever and vertigo. The treatment must be immediate to be successful, and the method preferred by the author for the exhibition of the quinine is by hypodermic injection.—*Il Policlinico*, April, 1904.

Comparative Value of Methods Used for the Cure of Hydrocele.—Jean de Smeth, after carefully reviewing this subject, concludes that expectant treatment, the application of compresses for the purpose of resolution, simple puncture, or puncture followed by the injection of alcohol, are the methods which are often successful in the treatment of infantile hydrocele, but which are not to be recommended for the adult. Injection of iodine is a method of treatment which ought to be abandoned on account of its dangers and the uncertainty of the results. The method of Bergmann—the total resection of the parietal layer of the tunica vaginalis—is the only method which can be relied upon to bring about a rapid and definite cure.—*Journal de Chirurgie et Annales de la Société Belge de Chirurgie*, February, 1904.

A Case of Carcinoma of the Liver.—Giovanni Galli publishes a case of cancer of the liver which simulated aneurysm of the abdominal aorta. The patient was fifty-four years old, a confirmed drinker, and had had venereal disease for which he had been treated. His symptoms began with heaviness in the stomach and pain after eating, but without vomiting. The abdomen became increased in size, not painful, with no œdema or increase in size of the abdominal veins. The inguinal glands became enlarged, and there was diffuse pulsation of the abdomen near its center, synchronous with the beat of the heart. There was a rounded projection the size of an orange over the liver. Toward the end of the case there was vomiting; and examination of the stomach contents showed no free hydrochloric acid. Autopsy showed a carcinoma of the cardiac region of the stomach from which the disease had extended to the liver The author states that in this case the localized pulsation, the distinct character of the abdominal swelling, the size of the liver, with the absence of stomach symptoms, and the superficial character of the swelling, might have justified the diagnosis of aneurysm.—*Gazzetta Medica di Roma*, April 1904.

A Clinico-statistical Study of the Sarcomata Observed in Eighteen Years in the Surgical Clinic of Francesco Durante.—These cases, seen in the surgical clinic of the University at Rome, from 1885–1902, were 167 in number. Of these tumors five were of the suprarenal capsule. From the author's tables he deduces the following observations: Heredity was observed in only 8 out of the whole number of cases. The frequency of sarcoma increases from youth up to the fortieth year. It is most frequent from forty to fifty, then decreases to the seventieth year. Trauma in the form of blows, etc., was observed in 19 cases before the appearance of the growth. Dental caries occurred in 16 cases preceding sarcomata of the jaws. As to results: 17 cases were inoperable; from 140 operations the immediate result was successful; 118 cases were followed for some time; 40 were radical cures; 71 had recurrences; 31 remained definitely cured after three years. The greatest percentage of cures was in sarcomata of bone, especially of the jaws. The reason of this is thought to be in slow growth of the sarcoma in bone, this being more marked in the jaw bones because of their solid character and the small number of blood-vessels.—*Il Policlinico*, No. 24, 1904.

The Rhythmical Pulsating Pain of Renal Colic.—Angelo Signorelli reports a case of renal colic which exemplifies the rhythmical pulsating pain which accompanies renal colic, and which he considers to be peculiar to this affection and of diagnostic value. Pain began in his case in the lumbar region and radiated along the ureter into the inguinal region of the same side and into the testicle. This pain was continuous, and had exacerbations and remissions. He had also a sense of rhythmical hammering beginning in the kidney and extending into the testicle. After a violent attack of colic, a calculus was passed after irrigation of the bladder. The rhythmical, pulsating pain can be observed in all cases of renal colic, and is characteristic of it. The usual pain is lancinating, and either continuous or intermittent. This peculiar pain is present during the violent colic and ends with the passage of the stone in the bladder. Its diagnostic value is both direct and differential. Most authors refer it to the reflex spasm of the muscle of the ureter and pelvis of the kidney, from the presence of the calculus. The pain is at the seat of the foreign body and is due to the offense of its presence, and its pressure on the sensitive nerve terminations, which excites the muscle to contract. Also the damming back of the urine, and the increase of tension in the urinary apparatus and stretching of the ureter and pelvis are factors in the production of rhythmical pain. Its rhythmic character is due to the increase of tension in the arteries obstructed by the calculus, and the stroke of the hammering is synchronous with the pulsation in the arteries.—*Rivista Critica di Clinica Medica*, April 2, 1904.

Book Reviews.

AIR, FOOD, AND EXERCISES. An Essay on the Predisposing Causes of Disease. By A. Rabagliati, M.A. w York: Wm. Wood & Co., 1904.

is rather original thinker and observer presents a rd edition of the above work, much amplified and writ- up to date. It is regrettable that his ideas could not e been conveyed in a more condensed form. The , however, of the theoretical considerations herein tained amounts to this: Eating too much and too quently produces an overplus of lymph in the connec- tissues of the body, and this he says "appears to be basis upon which the great mass of disease is built. excess of lymph or waste products produces a series connective tissue changes beginning with congestion terminating in hypertrophy. The resulting diseases responding to the varying stages. Of those affections which microorganisms play an apparently etiological t, his view is this: "The disease is not caused by the illus, but by the state of the body which makes the illus flourish," adding that "disease is essentially one h many aspects and phases."

His treatment for this "one" disease, with its many ects and phases, in which the cause is so well under- od, is naturally, first and last, limitation in diet to the nt of assimilative equilibrium. To judge from cases cites, the results are worthy of his convictions.

In the author's estimation, "exercises," from either a ventive or curative standpoint, are of doubtful e, if the habit of persistently overloading the tissues h an excess of food products is persisted in. As a ans of physical diversion and mental stimulus, they , he admits, to be endorsed.

His views on this question, however, appear to us to be ed on theory rather than actual experience.

The chapter "on the quantity and quality of food re- ired by man" contains much that is profitable to the dical as well as to the lay public.

ACTICAL GYNECOLOGY. A Comprehensive Textbook for Students and Physicians. By E. E. MONTGOMERY, M.D., LL.D., Professor of Gynecology, Jefferson Medical College; Gynecologist to the Jefferson Medical College and St. John's Hospitals; Consulting Gynecologist to the Philadelphia Lying-in Charity, and the Kensington Hospital for Women. Second Revised Edition. With five hundred and thirty-nine illustrations, the greater number of which have been drawn and engraved especially for this work, for the most part from original sources. Philadelphia: P. Blakiston's Son & Co., 1904

e second edition of this well-known work is only an lded testimonial to its merit. Many changes have been de in this revision, although the original plan of pre- nting the subject matter in the form of sections rather an in chapters has been undisturbed. This arrange- nt seems peculiarly well adapted to the needs of stu- nts, while it is very convenient for the physician who shes to consult a reference work. The author has pre- nted here not only the experience and methods of other ecialists, but also the fruit of his own rich experience. the present volume he has confined the consideration malformations to congenital conditions, while he con- ders the lesions of parturition under the term of trauma- ms. Disorders of the ovary and Fallopian tube are ecifically treated in Inflammation. In the section deal- g with genital tumors, extensive change has been made the consideration of myomata and malignant growths. this volume the reader will find that the later operative ocedures have been treated in greater detail. The ger part of the work has been rewritten to attain this d. The number of illustrations has also been increased d many of them have been redrawn. A large number the microscopical drawings of the first edition have been placed by new illustrations drawn from material taken om the writer's own practice.

LEMENTS OF SURGICAL DIAGNOSIS. By A. PEARCE GOULD, M.S. London, F.R.C.S. England. Surgeon to the Middlesex Hospital; Member of the Council of the Royal College of Surgeons of England, and of the Examining Board for England; Member of the Senate of the University of London. Third Edition. Revised and Enlarged. Chicago: W. T. Keener & Co., 1903.

In the present volume the author has reached his third dition, for which the entire text has been revised, while uch of it has been rewritten and many additions have een made. To the chapter on Diseases of the Head, a ection on the Diagnosis of the Intracranial Complications f Middle-ear Disease has been added. There are new hapters on the Diagnosis of Abdominal Tumors and of ertain Acute Abdominal Diseases, which are now treated urgically. Aside from these changes, the author has not ltered the general plan of the book. He states in the pref- ce that his aim has been to present those principles of iagnosis which apply in all cases and under all circumstances. He gives the application of these principles to the diseases and injuries of various regions as fully as possible. The diagnosis of injuries has been separated from that of diseases on account of the greater simplicity of this method. The importance of Bacteriology, Skiagraphy, and Blood Examination in the art of surgical diagnosis has been emphasized.

THE MEDICAL EPITOME SERIES. ORGANIC AND PHYSIOLOGIC CHEMISTRY. A Manual for Students and Practitioners. By ALEXIUS MCGLANNAN, M.D., Associate Professor of Physiological Chemistry, Instructor in Clinical Laboratory, College of Physicians and Surgeons, Baltimore, Md. Series edited by V. C. PEDERSEN, A.M., M.D., Instructor in Surgery and Anæsthetist and Instructor in Anæsthesia at the New York Polyclinic Medical School and Hospital; Deputy Genito-Urinary Surgeon to the Out-patient Department of the New York Hospital; Physician-in-Charge, St. Chrysostom's Dispensary; Anæsthetist to the Roosevelt Hospital (First Surgical Division). Illustrated with nine engravings. Philadelphia and New York: Lea Brothers & Co., 1904.

THE author in his preface clearly states the purpose of this little volume, which has been to select from the accumulated mass of knowledge on this subject the facts essentially important to medical students and practitioners and to present them in a clear and comprehensive style. This plan necessitates dogmatic statements, even when the question discussed may be a mooted one. The most generally accepted hypothesis, however, has been given in such cases. The little volume is well up to the standard of this excellent series.

THE NUTRITION OF THE INFANT. By RALPH VINCENT, M.D., member of the Royal College of Physicians. Physician to the Infants' Hospital; late Senior Resident Medical Officer, Queen Charlotte's Lying-in Hospital. New York: William Wood & Company, 1904.

THIS volume teems with interesting information which is the outcome of years of study and experience. In the preface the author tells of his dissatisfaction with the methods of infant feeding until he became acquainted with the work of Rotch. He thoroughly tested the percentage method propounded by this master of the art of infant feeding, and with the most gratifying results. The author calls attention to the marked variations which exist in the milk of nursing women. He gives various analyses made by different authorities on the subject. Substitute feeding is carefully considered in its various details, and several tables are given, among which are the "Practical Composition of Certain Percentage Mixtures" and the "Possible Variations of Mixtures with Divided Proteids." In the chapter on "Artificial Feeding" a number of well-known infants' foods are analyzed. The writer emphasizes the importance of nitrogenous extractives, which he believes probably play an important rôle in the infant's nutrition. Careful attention is given to the subject of milk-supply and the modification of milk. Bacteriology in relation to milk and to digestion is discussed. The last chapters are devoted to the consideration of the chemistry of infantile digestion, the diet of the infant in relation to growth and health; the normal development and general examination of the infant, the mortality and disease occurring in infants, and various diseases to which they are subject.

MANUAL PRATIQUE D'HYGIÈNE A L'USAGE DES MÉDECINS ET DES ÉTUDIANTS. Par le Docteur GUIRAUD. Professeur d'Hygiène à la Faculté de Médecine de l'Université de Toulouse. Troisième Édition. Revue et augmentée. Paris: G. Steinheil, 1904.

THIS volume of nearly eleven hundred pages is a very comprehensive treatise and discusses many and varied topics included under the general term of hygiene. The author begins with the consideration of such general subjects as the sun, the atmosphere, the classification and characteristics of climates, and potable waters. He discusses them all in detail, starting with the geological constitution of the sun, its physical properties, and its relations to air and water. The heat of the sun, its organic elements and their transformations, and its microorganisms are all included. The construction of houses is treated as to their situation, relation to the sun, building materials, interior arrangements, etc. The various methods of ventilation, heating, lighting, and disposition of water are discussed at some length. School hygiene military hygiene, professional and industrial hygiene, hygiene in relation to public buildings of various kinds and hygiene in relation to cemeteries have sections devoted to their treatment. There is a long chapter on diet and foods and a concluding chapter on the organization of public hygiene and sanitary legislation. This is the third edition of this work, but from time to time, as the author states, improvements take place which call for the revision of the older work. The book will appeal to all interested in this subject.

Society Reports.

Stated Meeting, Held April 25, 1904.

WENDELL C. PHILLIPS, M.D., PRESIDENT.

Bacteriological Experiments Relating to the Transmission of Typhoid Fever by Means of Infected Oysters.—CYRUS W. FIELD, Assistant Bacteriologist, Department of Health, told of the work carried out at the aquarium where oysters were supplied to determine two points: first, whether oysters carried the typhoid infection and, second, under what conditions and how long a time. Oysters were placed in large tanks containing brackish water which was infected with typhoid bacilli. At the end of twenty-four hours the oysters were removed, and it was found that the typhoid bacilli could be isolated from the oyster as late as the ninth day; in other words, it was shown that the oyster could carry the typhoid bacilli alive for nine days. Again the infected oysters were placed in salt water, and it was found that the typhoid bacilli could be isolated up to the eight day, but from the ninth day on no organisms could be obtained alive. When the tank was first infected there were found 20,000 organisms to the c.c., and at the end of twenty-four hours they had dropped to 10,000, or 50 per cent., and at the end of nine days none were found. It was shown that the death of the typhoid bacilli in oysters was brought about by the salt water, and again by dilution. He said that Cook of New Haven, in 1895, had some to the same conclusion or results, that the typhoid bacilli were destroyed in oysters at the end of the ninth or tenth day, but he also found an interesting thing. If the oysters were cooled he was then able to isolate the typhoid organisms at the end of from four to six weeks. Further experiments showed that many oysters die in transit to the market, and that the typhoid bacilli in dead or dying oysters make a very favorable culture medium for the organisms to increase.

The Oyster as a Possible Agent in the Transmission of Typhoid Fever.—Dr. WALTER BENSEL, Acting Sanitary Superintendent, Department of Health, showed by means of lantern slides that many of the oyster beds near New York City were polluted by sewage, excreta, chemicals, etc. His investigations were conducted in the neighborhood of Freeport, L. I., the Rahway river, Princess Bay, Lemon Creek, Godine Creek, Great Kills, S. I., and Indian Creek, Jamaica Bay, and New Haven, Conn., near the mouth of the Quinnipiac river. Oyster beds in these various localities were pictured and demonstrations made showing many sources of possible infection.

Some Considerations of the New York City Milk Supply.—Dr. WILLIAM HALLOCK PARK, Assistant Director of the Research Laboratory of the Department of Health, said that as time went on and population increased in New York City, we had greater difficulty in gaining definite knowledge as to where our food was coming from. He demonstrated by means of charts the milk supply coming from Pennsylvania, Massachusetts, Connecticut, and New York, all the milk being brought by railroads; in other words, the milk supply of New York City came from territory 300 miles across and 300 miles up and down, *i.e.* 90,000 square miles of territory. He said the question naturally arose as to what New York was doing toward looking for purity of food. Outside of New York City there was not much to be done because it was outside the jurisdiction of the local Board of Health; it was hardly possible, with the limited amount of money at hand, to inspect 90,000 square miles of territory. But, when they received word of bad conditions an inspector was sent, and samples of milk obtained, examined, and if found to be bad, an endeavor would be made to correct it. Nothing further than that could now be done unless more money was furnished the department. In some cases the farmers were instructed to do certain things, and often they readily complied. In the city no trouble was experienced in handling these milk conditions. The milk was inspected as it came in on the railroads, samples taken and tested. During the summer months both bacteriological and chemical examinations were made frequently.

Three years ago he made an interesting personal observation. A sample of milk sent to the laboratory showed 500,000,000 bacteria to the cm., and he took a trip to see where this milk came from. He found that the wagons carrying the milk were brought to the cars at 3 o'clock P.M., and placed in them. The doors were left open and the sun shone directly on the cans which were not protected by any ice. The cars were left until 5 o'clock when they were brought to New York, without ice.

He said he had had another interesting experience within the last two or three months showing how we were in danger of infection. In December last he was called to investigate an epidemic of what was supposed to be scarlet fever about thirty miles from New York up the Hudson River. The milk from a very good farm had been inadequate to supply the demand so this farmer had obtained milk from an adjoining farm. In this cow stable there was not even a window, and within it was found a septic cow, from which milk was taken only three days after calving; this milk was found to be filled with streptococci and infected thirty school boys who partook of it, giving rise to what was supposed to be a scarlet-fever epidemic.

With regard to the Milk Commission, he said this was started because of the inadequate amount of money allowed to carry on the work in this vast territory properly. It would require many inspectors to cover the ground and get better farms, clean cows, better water supplies, etc. This milk commission would have to continue to exist and come between the farmers and the consumers until more money was available. The city gave the laboratories to this commission for its work, the railroads gave passes to the inspectors, and every facility was to be had for carrying on this work at present.

With regard to certified milk and inspected milk, he said the people cared more for the certified milk probably because they would not take the trouble to ask for the inspected milk. He asked that the members of the society should endeavor to increase the demands not only for the certified milk, but also for the inspected milk, which costs either 8 or 8½ cents a quart.

New York City Water Supply, with Particular Reference to Possible Contamination with Typhoid Fever.—Mr. HARRY E. BRAMLEY, Chief Sanitary Inspector, Department of Health, read a paper on this subject. He said there were two chief water supplies for Greater New York, from the surface and from the underground source. A consideration of the former source was unnecessary because it was presumably pure. After treating of the water supplies to New York City from the earliest history he next considered the measures which could be adopted at present to prevent pollution of the present water sources as follows: (1) By the acquisition of more lands to meet the needs of the situation, a difficult matter at present because of the difficulty in obtaining titles to the land; (2) to compel the tenants in the neighborhood of the water supplies to introduce proper systems for the disposal of their wastes; (3) by combating the constantly recurring nuisances; (4) the instillation of filtration plants. He recommended that, at present, the instillation of properly equipped and efficiently controlled filtering plants would be the best means of preventing possible contamination of the water with typhoid-fever germs.

The Legal Aspect of New York City's Control of Its Own Watersheds.—HARFORD P. WALKER, Esq., Assistant Corporation Counsel, took up this question. The ideal control he said would consist in municipal ownership of several hundred feet on either side of lakes and streams

ich contributed water to this city. So far $7,000,000 l been spent for this, and he had no doubt but that the ure would show entire control of this extent of territory oining the lakes and streams. But while waiting for h an ideal control we should look for other aid. The bster Act was an excellent one to relieve the present ıation but, unfortunately, it ran but three years. This ı a good law because it gave the Department the right go ahead and remove any nuisance or contamination ich threatened our pure water supply. He spoke of the iculty encountered in getting anything done because so much red-tape, saying that the following was the ıal unsatisfactory course pursued: (1) inspection was de; (2) order was served; (3) re-inspection made to if pollution really existed; (4) State Board of Health ı notified; (5) State Board of Health made an inspec-n; (6) report made to State Board of Health; (7) te Board of Health orders local Board of Health to ıbat the nuisance; (8) local Board of Health does no-ng; (9) municipal attorney may bring an action. There-e, he realized the hopelessness of doing anything.

In conclusion he said the best method for protection of ter supply was municipal ownership of several hundred t on either side of lakes and streams, and this would t about $5,000,000. The next best method would be, his opinion, the revival of the Webster Act which gave e right to enter and remove any nuisance and pay the mages afterward. The introduction of a filtration nt he believed to be a good method if feasible.

Dr. Daniel Lewis, President of the State Board of ealth, continued the discussion. He said that municipal nership of our watershed was gradually being acquired, d also that there was a public health law which provided method whereby a law might be enacted by the State protect the watershed from pollution. To be sure, ch a law could not be enforced if resistance were shown, t during the past fifteen or twenty months a dozen cases d been met with and no difficulty encountered whatever. st year word was received that a number of infractions the rules had been discovered about the Croton water-ed; instead of any red-tape being required within teen days every one of the cases had been investigated competent civil engineers, and in less than twenty-one ys a report had been filed with the proper authorities. hy suits in these instances had not been brought he did t know, because they were all ready to be. If but one two convictions had been effected it would have had a ry good effect in preventing more suits and the people uld have been more likely to keep within the law. r. Lewis referred to one bill that had been introduced hich really was an amendment to the public health law one particular, namely, that inspections by the State oard of Health might be dispensed with. He referred iefly to another bill which differed from one already isting by about five words, and stated that the owner f the property who was required to abate a nuisance uld not be compensated by the city if the nuisance had en established since the rule was enacted. Dr. Lewis hought that was good ruling. He asked that these ques-ions be considered in a broader light than shown at this eeting, for the owner of property outside of New York ity should have the same protection as those living in the ity.

Dr. Lewis said that the State Board of Health was nxious to coöperate with the local Board of Health r the protection of their water and milk supplies. He id not think it fair to criticise the State Board of Health ecause they looked a little to the interests of the people living outside of New York City. He said the discussion did not seem to be apropos to existing things but that it might be to future conditions, because the water supply to New York City was the best in the United States.

Dr. William Hallock Park took this opportunity to thank Mr. Weiting, Commissioner of Agriculture, for the valuable assistance he had rendered the Research Laboratory in the pursuance of its work.

Dr. Thomas Darlington, Commissioner of Health, was the guest of the society and, in a brief address, thanked Dr. Lewis and the State Board of Health for their hearty coöperation in the health affairs of New York City. He also thanked the Medical Society of the County of New York for the valued assistance given the local health board, not only morally but financially.

Special Report of the Counsel of the Society.—Mr. Champe S. Andrews reported two unique cases that had come under the observation of the counsel during the past thirty days.

The man in the first case was known in connection with one of the so-called "Koch Lung Cures." At the recent Tuberculosis Congress in Germany this man hung around the hotel register until the original Koch had registered and then placed his name immediately beneath. He then had a photograph taken of the signatures which was used to make people believe he was the original Koch. He established the so-called "Koch Cures" all over the United States, in Boston, Baltimore, Pittsburgh, Chicago, St. Louis, Washington, New York City, and elsewhere. In New York City he had two registered physicians with him. With the coöperation of the New York *Herald* the counsel succeeded in exposing this man last March, when he was captured in Washington and he now rested behind prison bars. This man the counsel hoped to get rid of.

The second case was that of a man who had a rather unusual diploma. This man was interested in having the bill passed at Albany, legalizing the practice of osteopathy and which the County Society had spent so much money in combating. He was the president, secretary, first vice-president, and the whole faculty of what was termed the "Anatomio-Vitio-Americanio College," which was caught issuing medical diplomas for which he charged $550. At last the counsel succeeded in having him arrested on the charge of using the title of M.D. It was then learned for the first time that he was the introducer of this bill legalizing the practice of oteopathy in the State of New York. Further action in his case would be taken up at once.

Cincinnati Academy of Medicine.

At a regular meeting, held April 11, Dr. W. McLean Ayres gave a demonstration of the Thorner and Geneva Demonstrating Ophthalmoscopes; he also gave a short history of the ophthalmoscope, this was followed by the paper of the evening by Dr. August Ravogli.

"On Public Prophylaxis of Syphilis and Venereal Diseases." He said in brief: The statement that the regulation of prostitution means the legalization of crime is absurd and hypocritical. Prostitution has existed since the remotest times and has always been subject to regulation. It is shown by the Books of Moses that it was common among the Jews, and Moses established laws to check it. Adultery and rape were punished by death. In Leviticus he forbade intercourse with persons affected with flow from the genitals. These restrictions were continued until Solomon repealed them and soon Jerusalem was overrun with harlots.

In Athens Solon established houses filled with female slaves and the proceeds went to build a temple to Venus. The Dicteriades who kept these houses were isolated and compelled to wear a special dress. The abduction of a free Athenian girl to one of these houses was punished by death. In Rome, under Augustus, prostitutes were compelled to register in the office of the ædile, and when once registered nothing could wipe away the brand. Roman physicians refused to treat secret diseases, but under Nero public physicians were appointed for this purpose.

Charlemagne scourged all prostitutes, but excused the concubines of the rich. Louis VIII of France tried to regulate prostitution without result, but Louis IX

checked the progress of the evil by exile, but later milder measures were found necessary. From Louis IX to Louis XIV there was continuous alternation of severe penalties and repeals of the same. Under the Commune prostitutes were left alone and Paris streets were rendered unfit for respectable women; this led to complaint, and in 1796 they were again controlled.

In England, in 1430, those suffering from syphilis were excluded from the public houses.

In 1810 a dispensary was erected in Paris and a medical staff visited the prostitutes regularly. At present the regulation of prostitution in Paris is a model. The houses cannot be near a principal street, church, or school. Each girl must have a separate room and no back or side doors are allowed. Abundant utensils, water and soap, must be at hand. A woman, to keep a brothel, must apply to the police—she must never have been condemned for crime and must be of sober habits. Each girl must be reported to the police within twenty-four hours of her arrival. Prostitutes are inscribed in the Bureau des Mœurs. Each girl is taken before the Bureau, her parents or friends are notified and she is only inscribed if they fail to interfere. Once a week each prostitute is examined and those diseased are sent to the hospital.

In Spain the government takes no notice of prostitutes, but in Seville the first-class houses retain physicians, whose office it is to examine the women.

In London prostitution is unrestricted, and 50,000 houses of prostitution are said to be in the city and a constant trade in women for this purpose is carried on between London and Paris, London and Hamburg, and London and the country. Some are hired for this purpose, but many are decoyed by offers of legitimate employment. In St. Bartholomew's Hospital, of 5,327 out-patients, 2,513 were venereal cases. In 1892 of 196,336 soldiers of the British Army, 52,155 had been sent to hospital with venereal disease.

In 1871, before the abolition of the "Acts of Contagious Diseases," soldiers to the extent of 21.2 per 1,000 had been received in hospital with secondary syphilis, while after the abolition these increased to 33, 35, and 37 per 1,000. In India nearly one-half the soldiers have syphilis. In the period, 1874-79, under strict regulation of prostitution, 9.53 per 1,000 of the soldiers in military hospitals had venereal disease, but after this was abolished the number increased to 17.46 per 1,000, and the daily average of soldiers off duty for this cause was 4,191.

Among our own soldiers in Cuba and Porto Rico in 1898-99, syphilis reached 28.38 per 1,000 among the regulars and 50 per 1,000 among the volunteers. In the Provinces of Matanzas and Santa Clara, Cuba, venereal disease infected 171.28 among the regulars and 115.69 among the volunteers. The colored troops reached 195.92 against 127.35 in the United States. In these places prostitution was uncontrolled.

In Italy prostitution was controlled under Cavour, but under Crispi, 1888, this was abolished, and in the Ospedale Maggiore in Milan venereal disease increased from 5,916 patients in 1887-88 to 7,570 in 1888-89, and in the Maternity it increased in pregnant women from 1.28 per cent. to 4.27 per cent. In the Foundling House children with hereditary lues numbered 23 in 1887-88, 49 in 1888-89, and 98 in 1889-90.

The writer agrees with Neisser and Behrend in thinking that all prostitutes should be regularly examined, and if diseased sent to the hospital until all danger of infection is passed.

In Cincinnati, in 1894 Mayor John A. Caldwell started a system of protection. Detectives were detailed to watch these houses, and the keepers were compelled to report all inmates and to report cases of disease; these were sent to the Cincinnati Hospital. The following number of cases were treated in this hospital in 1890, 117; in 1891, 164; 1892, 131; and in 1893, 142. In 1894 the number rose to 224; in 1895, 220; in 1896, 182; and in 1897, 194, because of the new system; then, in 1898, the system was abolished under Mayor Gustav Tafel, and the numbers dropped to 144 and in 1899 to 149. The next Mayor, Julius Fleischman, reëstablished the system in 1900, and in the next three years the number treated increased to 224, 529, and 324. During the years when treatment was not enforced the cases of gonorrhœa were all severe, and in many cases required operation, but during the years of protection the cases were sent in much earlier and were much milder. Syphilis in the secondary period came to the hospital during the years of freedom at an average of 28-32 cases; this rose to 94-124 in the years of protection and again fell to 37-53 when inspection was abolished; thus 50 per cent. of contagious cases of syphilis were allowed free to spread the disease. Since 1900 this matter has been in the hands of the Board of Health, and Dr. Clark W. Davis, Health Officer, has established the system as it is at present. All prostitutes are registered secretly at the office of the Health Officer, and all are examined once a week by a corps of examining physicians and, when diseased, are sent to the hospital. In 1903-04 625 women were registered as public prostitutes, and in one week, ending March 12, 1904, 482 girls were examined and 19 found diseased. Knowing that they will be examined, the women keep themselves clean and so reducetheir liability to infection.

In the new Cincinnati Hospital these patients will have a building to themselves which will be provided with working and sewing rooms, where they will be employed, and the writer hopes that Christian women will try to provide institutions for the rescue of these misguided creatures, where they can be taught and helped to find an honest occupation.

The Pittsburg Academy of Medicine.

Scientific meeting April 12, 1904, Dr. Ewing W. Day presiding. Dr. Montgomery reported a case of surgical kidney in a woman, the mother of one child. Menstruation was established at sixteen years, and had always since been painful. She had pain on the right side, and a mass thought to be the kidney, was found in the right pelvic region. A laceration of the cervix was repaired. A posterior incision in the vagina revealed healthy tubes; but a mass was palpated in the right pelvis, posterior to the peritoneum, and was diagnosticated as surgical kidney. Some relief followed the trachelorrhaphy, but dysmenorrhœa recurred after a few months, and threatened to lead to the morphine habit. There was some rise of temperature at times. At the next examination the mass was found lower and larger, but the doctor was certain it was not tubal. An exploratory laparotomy proved the tubes healthy as diagnosticated, and the right kidney to be in the normal position. In attempting to remove the mass from the right pelvic region the finger pushed through the rectal vein, producing severe hemorrhage. Patient is now doing well. Dr. Montgomery has not yet had an opportunity to catheterize the ureters to clear the diagnosis between downward displacement of the left kidney to the right side, and congenital third kidney.

Dr. Lichty referred to a case of Edebohls' in which the kidney had been removed through the pelvis, showing that excessive downward displacement is not impossible.

Dr. S. C. Milligan reported a case of a woman with a history of pain in the infrasternal space, emaciation, vomiting, and loss of appetite. Later she had a hemorrhage from the stomach with elevation of temperature. A diagnosis of ulcer of the stomach was made. The patient was put on a diet of milk and eggs; with rest in bed for three months, resulting in a cure.

Dr. Frank H. Murdock read a paper on "The Indications for Surgical Intervention in Chronic Gastric Ulcer." He said, in part, as follows: Acute gastric ulcers are more common in women than in men; and occur mostly between the ages of fifteen and twenty-five. They are situated along the upper margin of the stomach; are multiple in 54

ent.; hemorrhage occurs as a first symptom in 75 per ; and perforation as a first symptom in 3 per cent. nic gastric ulcers rarely occur before the age of thirty, ituated at the pyloris and are solitary in 87 per cent. ediately fatal hemorrhage occurs in from 3 to 5 per and perforation in 7 per cent. Hemorrhage occurs me time in 18 per cent. of the cases. The indications rgical intervention are perforation and hemorrhage; ugh recently well known English and American cur- s have advocated operation for the cure of ulcer itself. leath rate, however, from chronic gastric ulcer under r medical treatment is not more than 4 per cent., eas the mortality following gastroenterostomy for be- stenosis of the pyloris is from 10 to 50 per cent. He ed Leube's opinion and teaching in regard to operation he use of the stomach tube in gastric ulcer as follows: nsider an operation advisable if the ulcer is bleeding f this condition persists for weeks. If the patient has eding ulcer I feed him by the bowel while the bleeding . If the ulcer is not bleeding usually, do not use l feeding. In other cases only during the first three of treatment. I do not use the tube, or at least only ses with severe vomiting; and when I fear more from omiting than from the use of the tube. This is, how- , very rare.". Patients with chronic gastric ulcer ld be kept on liquid food, not for weeks, but for months ntil the ulcer heals. When this is done, recurrence, at t in his experience, is very rare, happening in only two of thirty-two cases which he had reported. Dr. ity endorsed the conservative views of Dr. Mur- h, also the emphasis he had placed on the slowness aling of gastric ulcer. He had had a case of seven s' duration. He said the pain in chronic gastric ulcer n comes, not immediately after eating, but somewhat r, differing in this respect from acute cases. A small ount of blood may not be vomited nor detected in the ls, yet the hemorrhage from an ulcer be enough to e anæmia. This should be borne in mind in searching the cause of an anæmia of obscure origin.

Dr. Joseph Willets read a paper on "The Advantages of tracting the Lens, without Iridectomy," with presenta- of patient. He reviewed the embryology and an- my of the lens and its protecting ligament, showing how y develop without blood-vessels, lymph channels, or ves, therefore unaffected by disease in other parts of body, and even in the eye itself. He said that the lens nstantly undergoing chemical, physical, and morpho- al changes, beginning in early childhood, so that un- plicated senile cataract is purely a normal physio- al procedure. In reference to the extracting the lens, prefers the simple method. He said that a pre- inary iridectomy necessitates two operations; causes a inct disfigurement, cosmetically; and a great annoy- e from diffusion of light from the increased size of the il. In cases in which the conditions are such as demand ectomy, he thinks it can be done to better advantage r expulsion of the lens.

The Orleans Parish Medical Society.

t the semi-annual meeting of this society, held April 1904, Dr. A. G. Friedrichs exhibited two pieces of ratus for treating fractures of the inferior maxilla. fractures in front of the angle he uses a horseshoe- d splint, molded to fit accurately over the lower . Wires project from this, to which are attached ive-plaster strips. These bind the dental splint to a shoe-shaped wooden splint which presses against ower border of the inferior maxilla. For fractures r above the angle the speaker uses webbing straps, h pass from the sinciput around the chin and from occiput around the forehead. Results were quoted a case exhibited to prove the advantages of the de- s.

r. A. Granger read a paper entitled "Intractable iting of Pregnancy Cured by Electric Currents, Illus- trating the Importance of Current Differentiation." After persistent nausea and vomiting in three pregnancies, two of which terminated in abortion, patient was seen in ninth week of fourth pregnancy. She had been treated for three weeks by every method, including the Apostoli galvanization. Brief applications of Faradic current with the positive pole over the cervical vagus, or over the back of the neck and the negative over the epigastrium stopped nausea and vomiting after nine days. A relapse was successfully treated in the same way. The writer urged that electrotherapeusis be considered as rational and not empirical.

Dr. L. Perrilliat reported a case of "Probable Intraligamentary Hæmatoma Following Tubal Rupture." The object of the paper was to bring out the importance of a careful history of the case, together with the signs of ruptured extrauterine pregnancy, in establishing the diagnosis. The treatment of these cases differs from that of other forms of ruptured extrauterine pregnancy on account of the anatomical conditions circumscribing the hemorrhage. Dr. Perrilliat's case, a multipara twenty-seven years of age, presented herself at his clinic with a history of a five weeks' tubal pregnancy terminating in rupture three weeks previously. On examination hæmatoma of the broad ligament was diagnosed. Patient recovered after two weeks' rest in bed, with colonic flushings to prevent possible infection of the clot. Tumor had almost disappeared.

College of Physicians of Philadelphia.

At a stated meeting, held April 6, Dr. Joseph Sailer read a paper entitled "Aortic Regurgitation," presenting a critical summary of the recent developments in the symptomatology and diagnosis of this disorder, supplemented by a record of personal observations.

Dr. W. W. Keen read a paper entitled "Report of a Case of Enormous Mixed Tumor of the Parotid Region, with Presentation of the Patient." The tumor had been present for more than twenty years, only recently increasing rapidly in size, in the sequence of manipulation on the part of the physician. The mass became so large and so heavy, reaching down to the clavicle, as to be almost unbearable by reason of its weight, and the patient, who was more than sixty years old, remained in bed a good deal to avoid the resulting annoyance. In going about he was compelled to support the growth in a sling. On one occasion rupture took place, and about two pints of bloody fluid escaped. The patient finally consented to have the new growth removed, and its dissection and ablation were accomplished with some little difficulty. The wound became infected through the saliva, despite the utmost precautions, and healing was, as a result, retarded, but perfect union eventually took place. Histologically, the tumor was found to include several different varieties of tissue.

Dr. John B. Deaver read a paper entitled "The Surgery of the Prostate," reviewing first the history of the subject and considering in detail the various procedures that have been recommended in the treatment of the condition named. His own preference, based upon personal experience, as well as that of others, is for suprapubic cystotomy, followed by enucleation of the enlarged organ.

A resolution was adopted providing for the appointment of a committee to secure plans, specifications, and bids for the contemplated new building to be erected on the lot purchased by the college, and to make a report in the coming autumn.

College of Physicians of Philadelphia, Section on General Medicine.

At a stated meeting, held April 11, Dr. Albert P. Francine exhibited "A Case of Phthisis of the Base of the Lung." The patient was a man who had passed through the hands of a number of practitioners without thorough

examination and a failure to detect the physical signs, namely, dulness of percussion, blowing breathing, with crackling râles and increased vocal resonance. The symptoms were distinctive and the sputum contained tubercle-bacilli.

Dr. Charles B. Worden made "A Preliminary Report upon Some Experimental Nutritive Enemata." He made studies, with the aid of the *x*-rays, of the distance to which nutrient enemata, to which bismuth was added for purposes of demonstration, advanced in the bowel, and found that they did not pass beyond the ileocæcal valve.

Dr. Joseph Sailer made a report of "Some Cases Showing Lesions of the Cardiac End of the Stomach."

Dr. Charles H. Weber made "A Preliminary Report of a Case of Splenomyelogenous Leukæmia Showing Marked Improvement under the use of the *X*-ray."

Dr. J. Alison Scott made some remarks upon a case of similar character.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending May 21, 1904:

	Cases.	Deaths.
Measles	1482	39
Diphtheria and croup	400	49
Scarlet fever	392	26
Smallpox	...	...
Varicella	88	...
Tuberculosis	475	187
Typhoid fever	45	8
Cerebrospinal meningitis	...	82

Appendicitis in the China Fleet.—F. H. A. Clayton states that, from information obtained from other medical officers as well as from his own observation, it would appear that quite an unusual number of appendicitis cases come under treatment on the China station. The usual developmental and anatomical peculiarities predisposing to attacks are no doubt present in these cases as they are in others, but the writer adds that in seeking to discover special factors, one is struck by the fact that the China station is that chiefly productive of digestive and intestinal disturbances, and probably also that more men of this station are affected by intestinal parasites than any other. The frequency with which Europeans resident in tropical countries act as hosts of ascaris and trichocephalus is a matter of common knowledge, but as far as the navy is concerned, this station seems to be especially responsible, as is borne out by the most recent health returns. The association of these parasites with dyspeptic disturbances and with catarrhal processes in the intestines, is, in the writer's experience, quite common among men on this station, and it is interesting to note that with appendicitis here diarrhœa rather than constipation is the rule. Several observers have suggested putrefying frozen food as a factor of appendicitis by the production of intestinal catarrh. There has been, for the last two years, a sort of epidemic prevalent in the height of the summer. At this time far more vegetable food, and especially fruit, is eaten by the men, and animal foods run more risk of decomposition. Consequently, digestive troubles are far more frequent. The presence of the common intestinal parasite quite possibly plays a part in producing a catarrhal condition, thus lowering the natural resistance and increasing the virulence of Bacillus coli and the other organisms in the canal, so predisposing to inflammatory processes. The wandering habits of ascarides must be kept in mind, with the consequent mechanical effects. The parasites may also convey other organisms. Finally, the small erosions produced by the parasites might readily act as the portal of entry of organisms. The writer notes some interesting cases.—*Journal of Tropical Medicine.*

A New Method for the Operative Treatment of Nephritis.—Bakes describes two possible modifications of the Edobohls' operations intended to secure a better blood supply to the decorticated organ. One procedure is to incise the peritoneum vertically and draw omentum into the wound. The kidney is wrapped in this as completely as possible and fixed with sutures. The second plan is that of dislocating the kidney intraperitoneally through a peritoneal slit and anchoring it after friction of the contiguous serous surfaces. The author has performed the first operation on a patient with satisfactory results.—*Zentralblatt für Chirurgie*, No. 14, April 9, 1904.

Health Report.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, U. S. Marine Hospital Service during the week ended May 21, 1904:

SMALLPOX—UNITED STATES.

			Cases.	Deaths.

ME THOUGHTS SUGGESTED BY THE STATISTICS OF THE HEALTH DEPARTMENT, ESPECIALLY CONCERNING TYPHOID FEVER AND SMALLPOX.*

BY GEORGE L. PEABODY, M.D.,
NEW YORK.

the annual tabular statement of the total number of deaths by principal causes in 1903 there is ich food for reflection, as there always is in these blications of the Health Department.

The first in the list of diseases is *typhoid fever.* e total number of cases of this disease reported for e year in the entire city was 3,671, and the total mber of deaths ascribed to this cause was 653,or out 18 per cent. The mortality in Brooklyn was .62 per cent., and that in Manhattan was only .54 per cent.

It is probable that this death rate is higher for th boroughs than it should be, owing to the fact at many cases of the disease are not reported at l—a fact to which I shall have occasion to recur—t I know of no reason to doubt its *relative* accuracy.

For purposes of comparison it may be interesting note in passing that in the New York Hospital, in 903, we treated 144 cases, many of whom came nder treatment late in the disease, with a mortality f 10 per cent.

While the figures above given show that the ratio f mortality to cases in Brooklyn was practically ouble that in Manhattan, it is very significant that he proportion of cases to population is very much igher in Manhattan than in Brooklyn. Thus in Manattan there were 13.35 cases per 10,000 of population, and in Brooklyn only 7.69 in the same number the year 1902; in the year 1903 the figures for the me two boroughs were 12.21 and 7.76 respectively er 10,000. Thus it appears that the ratio of cases of yphoid fever to population is almost twice as great in anhattan as in Brooklyn. While this showing rgues very badly for Brooklyn's therapeutics it is rtainly of very sinister significance in regard to ur own hygiene.

It is not unlikely that many of the ninety deaths ttributed in another column to malaria also belong mong the typhoids.

It is well known, too, that many of the lighter cases of typhoid fever—(both in hospital and in private practice)—cases in which death is at no time feared, are not reported to the Department at all. Only last year attention was called by the Department to the fact that one of our largest general hospitals was not in the habit of reporting any but fatal cases of this disease, and presumably that hospital was not the only sinner in this direction. For these reasons it is fair to assume that the Department's figures, while as accurate as they can at present be made, nevertheless understate the facts as to the number of cases of this disease that occur in this city. In the previous year the number of cases was nearly two hundred in excess of that recorded for 1903.

*Read at a meeting of the Practitioners' Society on Friday, May 6, 1904.

If, now, there occur in Manhattan every year between three and four thousand cases, which is probably not a high estimate, ought we not to pause and ask ourselves where they come from? What is likely to be the source or sources of infection in this large number of cases? Aside from occasional small epidemics in given houses or closely defined localities these are probably for the most part isolated cases of unknown origin. It is usually impossible to trace the origin of isolated cases.

Doubtless some of them originate elsewhere and come here during the period of incubation; and some are deliberately brought here for treatment, as was the case when the epidemic occurred last year at Ithaca.

Many of them, probably most of them, however, originate here, occurring, as many of them do, in people who have not recently been away and have had no known contact with others who have been ill.

It seems to the writer that the only common factor in the matter of possible etiology is the drinking water. You all know that Brooklyn's water supply is totally different and is in great part subjected to natural filtration through a sandy soil.

Of late years, for some reason which has not been explained officially, although it is probably owing to the increased consumption of water, we have been deprived of the benefits of our excellent storage system, to which sanitarians have always believed that we owed much in the way of immunity from typhoid fever. Instead, it has become obvious to all of us that surface-water from the water-shed is delivered in our houses without any such salutary intermediary. It is only of late years that a heavy rain to-day was pretty sure to be expressed in terms of mud in our bath-tubs tomorrow morning or the day after. The only explanation of this unpleasant circumstance is the direct transmission and immediate delivery of surface-water from the Croton water-shed. This water-shed is extensive, inhabited and not therefore guarded against pollution at every point, nor can it be.

Now, whether the present large number of cases of typhoid fever in Manhattan is traceable to the Croton water or not, we must admit its possibility as things now are, and the farther possibility of epidemics of great magnitude, if the present condition be allowed to continue.

It is absolutely inadmissible and unsafe to use as drinking water the surface-water that comes from an inhabited region without the intervention of a system of storage or filtration, or both.

It is small consolation to us to know that Philadelphia and other cities and towns of Pennsylvania and of this State are worse off even than we in this regard.

Prior to consolidation the statistics of Manhattan and the Bronx were not kept separately. For the eleven years prior to 1904 the number of cases varied very widely, *i.e.* between 792 in 1894, as a minimum, and 2,629 in 1902, as a maximum; but it is obvious

on referring to the statistics of the last ten years that there has usually been a very marked increase in the annual number. These are the figures for the years from 1894 to 1903 inclusive, for Manhattan and the Bronx: 792, 965, 1,002, 1,004, 1,535, 1,290, 1,759, 1,915, 2,629, 2,642.

It is proper to state that during these years these figures also include the disease reported as typho-malarial fever, which can fairly be assumed to be really typhoid fever, I presume.

During these years the population also increased, of course, but not in proportion to the increase in the fever rate.

The following table shows the number of cases per ten thousand of population reported in Manhattan and Bronx from 1894 to 1903, inclusive, with the exception of 1901, for which year I have no record of the population:

YEAR.	CASES.	POPULATION.	CASES PER 10,000
1894	792	1,809,353	4.37
1895	965	1,873,201	5.15
1896	1,002	1,906,139	5.25
1897	1,004	1,940,553	5.12
1898	1,535	1,976,572	7.76
1899	1,290	2,014,330	6.40
1900	1,759	2,053,879	8.56
1901	1,915	.....	....
1902	2,629	2,139,632	12.29
1903	2,462	2,186,017	11.26

While these figures do not show a uniform annual increase in the ratio of cases to population, they do seem to show in a general way an increase which is highly significant, and for which there must be some explanation. It has occurred to me that the larger amount of surface water that has come to us of late years, the very obvious failure of our storage system, to which allusion has already been made, may be responsible for this very marked increase in the ratio of cases to population.

The next column in the death-causes is *malarial fever*, to which were assigned, in 1903, 27 deaths in Manhattan, 36 in Brooklyn, and 90 in the entire city.

These numbers seem to me to be impossible, and they suggest inevitably errors in diagnosis on a large scale. They are not susceptible of any other explanation.

How many of us see deaths in ordinary times, due to malaria? Some may have occurred here during the Spanish war, and, years ago, during the period of the construction of the Panama railway we did occasionally see such a death; but at present I venture to believe that death from this cause in this city must be a great rarity.

Smallpox is the next disease to which a column is devoted. Our showing for 1903 in this regard is most satisfactory, namely, 43 cases reported and 5 deaths.

In connection with smallpox, forcible removal of the patient by the Health Department is of more than scientific interest.

It has long been my desire to ask for a discussion of this subject. There could be no better place for such a discussion than this society, which contains so many upon whom the Department depends for advice; and there could be no better time for it than the present, when smallpox is not prevailing.

If a patient can be suitably isolated in his home, so that neither he nor those in attendance upon him come in contact with those who are not protected by vaccination, the necessity for such a procedure is not apparent. The fact that it is still insisted upon in this city is naturally taken to indicate that vaccination is not considered to be protective here.

If such a practice were carried out with reference to almost any of the other infectious fevers it would be at least logically defensible, however it might be open to criticism from other points of view; but the selection by the Health Department of the only one of all the list of acute infections, which we all believe to be absolutely preventable by the easy establishment of artificial immunity tends to bring obloquy on sanitary science, and seems harsh and arbitrary and, in some cases, cruel.

If reasonable isolation is not practicable in the patient's home the case becomes different, of course. I am now referring to cases in private houses, so situated as not to be in contact with any but the necessary doctors and other attendants, and when these attendants may be counted upon to abstain from contact with the unvaccinated, or, as in the case of the doctors, to reduce that contact to a minimum.

Suppose, for example, that a member of your own family should develop smallpox. It should amply satisfy all the requirements of hygiene if the upper part of the house were to be surrendered to the patient's uses, and if none but those protected by vaccination were allowed in the part of the house reserved for him, and if those in attendance upon him kept apart from the unvaccinated as far as practicable and adopted all the usual means to prevent the spread of the infection. All of this might properly enough be supervised by the Department as a condition of leaving the patient in his home under the circumstances, and it might be somewhat expensive, but probably no more so than the present method of dealing with the condition.

It is probably not far from the truth to suppose that many of us, under present circumstances, would deliberately conceal the existence of this disease in our own families and take the risk of consequences, punitive and other; and from this it is but a short step to believing that we would do the same thing for a relation or a friend.

There can be no doubt that dread of the enforcement of this regulation *has* led to concealment and flight, and thus to much greater exposure than would occur under circumstances that I am advocating.

Although exceptions to this rule of forcible removal are occasionally made in the other boroughs, no exception is ever made in Manhattan.

It is within the recollection of many of us that smallpox was treated in the general medical wards of the Paris hospitals; and in France, Germany, Austria, and England such patients were treated in their own homes some years ago when I had occasion to be familiar with the facts in those countries.

This was the case in these continental countries where no one family occupied an entire house, but where many families lived together under one roof and used the stairs and waterclosets in common.

Twenty years ago this was the practice here; it would be interesting to know what causes led to so radical a change of plan.

In England, Section 124 of the Poor Law Act* tells us that under some circumstances a patient may be removed by the authorities to a hospital, but the circumstances are very different from those that we are supposing. Let me quote to you the section of the Poor Law Act so far as it relates to this subject:

"Where any suitable hospital or place for the reception of the sick is provided within the district of a sanitary authority, or within a convenient distance from such district, any person who is suffering from any dangerous infectious disorder, and is without proper lodging or accommodation, or lodged in a room occupied by more than one family, or is on board any ship or vessel, may, on a certificate signed by a legally qualified medical practitioner, and with the consent of the superintending body of such hospital or place, be removed by the order of any

* "Treatise on Hygiene," Stevens and Murphy, Vol. III, p. 164.

ıstice to such hospital or place at the cost of the ınitary authority; and any person so suffering who lodged in any common lodging-house may, with ıe like consent and on a like certificate, be so re-ıoved by the order of the sanitary authority."

The possibility of removing patients as a con-ıquence of erroneous diagnosis is a serious aspect f the case; and the unwillingness of practitioners to ıbject their diagnoses to official review, is in part ased upon a fear of this possibility.

Some years ago I saw a case of pustular eruption ıe to local use of croton oil which had been sent) the Health Department and kept over night as a ɔssible case of smallpox.

It has often happened to me to share the re-ɔnsibility with another doctor of making the ıagnosis between variola and varicella, and then) remind him of his duty to report the case to the lealth Department. Very commonly he says that e prefers not to do so, lest the family should be eedlessly alarmed if the case be one of varicella. lore than once he has told me that even if I believed to be variola he would not be willing to take any ıep which would tend to its forcible removal to ıe smallpox hospital.

This is probably not an unusual occurrence, and ; is likely to be repeated as long as the present ractice prevails; and thus the ends of hygiene and rophylaxis are likely to be defeated.

To revert for a moment to the possibilities and onsequences of erroneous diagnoses. As high an uthority as there is among us has told this society f the difficulty of making the differential diagnosis, nd of its actual impossibility in some cases; and re all know that the father of modern dermatology naintained till his death that the two diseases were dentical to the extent that either one might give rigin to the other.

During the past winter a dermatologist of inter-ıational reputation endeavored to persuade me that ı case of varicella which occurred in the person of ı doctor who was convalescing from a relapse of yphoid fever was one of smallpox, being misled by he height of the fever.

It is certainly possible for any of us to mistake he one for the other. I have known several ɔhysicians of large experience unable to distinguish ɐetween erythema multiforme and smallpox.

Moreover it is within the memory of most of us hat a mistaken diagnosis led to grave public ıcandal and to a successful suit at law in which sub-ıtantial damages were recovered from a reputable ɔractitioner whose sole offense was that he had ɐported a doubtful case to the Health Department, nd had thus become the unwilling cause of the patient's forcible removal, after diagnosis by one or more of the officers of the Department.

Thus the risk incurred by the practitioner in re-porting a case that he believes to be smallpox is not trivial; and his temptation to conceal it becomes proportionately great.

We are all so proud of the work which our health department has done in the multifarious spheres of its activity in the prevention and cure of disease, that we must be forgiven if we appear to be unduly sensitive when it lays itself open to attack, as it seems to the writer to do in this instance.

The next subject in the list to which I shall ask your attention is *diphtheria* and *croup*. By croup I understand laryngeal diphtheria to be meant. Of 18,317 cases reported for the entire city the total mortality is 2,190, or between 11 and 12 per cent. We may hope that the early and adequate employ-ment of antitoxin may reduce this death rate. A year earlier the mortality from this same cause was over 13 per cent.

It seems very strange that *hernia* and *intestinal obstruction* together should be responsible for nearly 500 deaths a year in the entire city. To be exact, it is recorded at 485 for 1903, and at 490 for the previous year.

It is very shocking to note that there occurred 4,068 deaths by *violence* in the entire city. In this category Manhattan leads all the other boroughs with 2,355, and is followed by Brooklyn with 1,144. The risk of a violent death is nearly twice as great in Manhattan as in Brooklyn, allowance being made for the difference in population; but in both of these boroughs the death rate from this cause seems shamefully high. It does not take much experience in the streets of this city to teach one the barbarously low value that is placed on human life here, and the utter recklessness with which danger to life is disregarded.

This very instructive publication supplies much food for discussion, but I will not increase this evening the tax that has already been imposed upon your patience.

57 WEST THIRTY-EIGHTH STREET.

PATHOLOGICAL DISTINCTIONS DISCERNIBLE IN THE RADIOGRAPH IN CERTAIN DISEASES OF THE LONG BONES.

BY EUGENE H. EISING, A.M., M.D.,
NEW YORK.
SURGEON TO THE GOOD SAMARITAN DISPENSARY; ASSISTANT RADIOGRAPHIST MOUNT SINAI HOSPITAL.

CORRECT interpretation of the radiograph or the skiagraphic plate supplies an aid in the differential diagnosis of certain diseases of long bones to which

FIG. 1.—Carcinoma of humerus, metastatic, with four weeks of local symptoms.

insufficient attention has been paid. I do not mean to imply that the exact nature of the bone lesion is invariably determinable from a study of the

radiograph, but, together with a consideration of the clinical symptoms, the radiograph often furnishes corroborative evidence. Beyond this, and often in cases in which the diagnosis is shrouded in obscurity, a good radiograph, properly interpreted, will surprisingly often throw the weight of evidence one way or the other.

It is my desire here to set forth a few points of difference that are readily discernible in the radio-

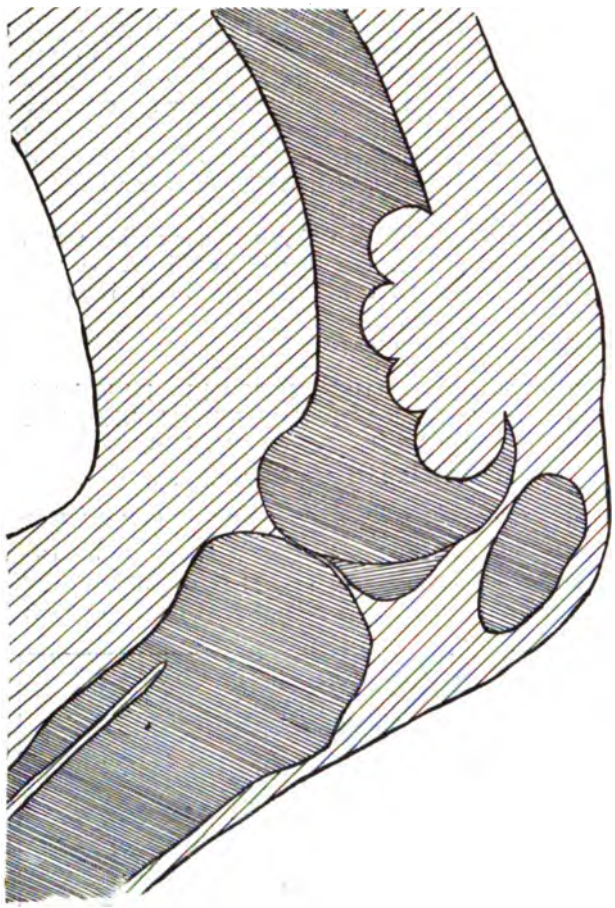

FIG. 2. Tracing of radiograph of a myeloid or giant-cell sarcoma.

graph and which seem to characterize, at least in a measure, certain types of bone disease, and with a large degree of probability suggest a difference between neoplastic and inflammatory processes.

The morbid processes that can enter into this differential discussion are limited. In this communication I have confined myself to a study of inflammatory and neoplastic conditions of bone.

In general, it is to be remembered that when periosteum becomes irritated its osteoplastic function becomes stimulated and new periosteal bone is formed upon its osteal surface. When periosteum becomes disturbed to the point of destruction or approaching that point, no such change occurs. A good radiograph will present various phases of periosteal alteration in certain bone lesions, and I believe permit of deductions that throw light not only upon the kind of irritation but often also upon the period of time that irritant has been active. The information furnished by the radiographic picture of the bone itself seems also to be more or less distinctive in accordance with the lesion.

A hemorrhage into periosteum or between it and bone, will be recognizable or not in the radiograph according to the age of the lesion, that factor determining the extent of new periosteal bone formation. A subperiosteal collection of pus may present the identical picture, but this point the clinical symptoms must determine.

The aim of this article is, however, to bring out points in differentiation between osteoperiosteal neoplasms and osteomyelitis, and for this purpose in treating of bone neoplasms, I am able to treat only of the two large groups of carcinoma and sarcoma without entering further into varieties, and in a general way to point out their radiographic characters.

The radiograph of carcinoma in bone shows an area of rarefaction which is circumscribed and rather sharply demarcated from neighboring bone. The area of carcinomatous rarefaction is homogeneous and does not give the mottled appearance to be detected in osteomyelitis. The area of rarefaction is medullary and not cortical. The size of the area of rarefaction is commensurate with the length of time of the clinical symptoms. The periosteum shows no evidence of new bone proliferation. The entire thickness of bone soon becomes involved in the process of rarefaction, and even spontaneous fracture occurs before there is much gross involvement of the other structures. Fig. 1 demonstrates these characters. The subject was a woman, thirty-eight years of age, suffering from carcinoma of the breast. The bone lesion is metastatic. The radiograph corresponds to four weeks' duration of local symptoms.

Of sarcoma of bone there seems to be two distinct groups from the radiographic standpoint. The one

FIG. 3. Spindle-celled osteosarcoma of tibia, showing fusiform dilatation of the shaft of the bone and widening of the medullary canal.

entirely characteristic, and from my experience always myeloid or giant-celled sarcoma, the other permitting perhaps of less certainty of diagnosis. The giant-celled sarcoma produces in radiograph a picture as represented schematically in Fig. 2. The radiograph shows an area of erosion of bone and periosteum, an area not of rarefaction, as in the case of carcinoma, but of bone resorption. The demarcation between the bone and area of absorption is

entirely clean cut and gives the appearance of having been accomplished with a gouge.

Unfortunately I am unable to furnish a radiograph of this type of tumor; such a radiograph is entirely characteristic of this group, and from it the diagnosis can be made with a great degree of certainty.

Spindle and round-celled osteosarcomata occurring in the length of long bones, present pictures different from the foregoing. These tumors usually cause a gradual fusiform dilatation of the shaft of the bone. In a good radiograph the medullary canal can perhaps be seen for the greater length of the bone, in which case it will be seen to widen out at the level of the growth. The periosteum can be seen very much thickened and of a different density than the soft tissues, but showing no proliferation of new bone. The bone itself is homogeneous, or at all events does not show the sudden transition of light and shade to be seen in radiographs of osteomyelitis (Fig. 3).

A study of the radiographs of osteomyelitis also shows features more or less distinctive. Osteomyelitis, accompanied by subacute or chronic symptoms, is the only variety that need be taken up in this relation.

The features characterizing osteomyelitis in the

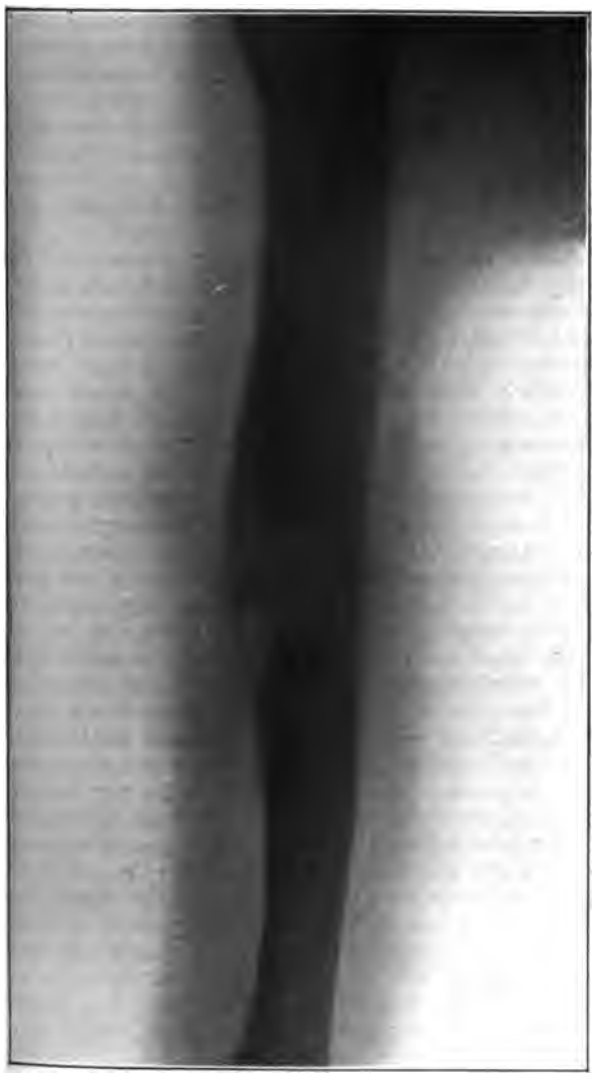

Fig. 4. Subacute osteomyelitis of humerus, showing mottled area of diseased bone.

radiograph are, a bone swelling occupying a segment of the bone or perhaps the entire length, irregularly fusiform, or else the tumor may be limited to one aspect. The area of disease presents a mottled appearance, the result of irregular translucency caused by liquified areas and small areas of density where bone has become thickened. Cloaca and sequestra can sometimes be seen.

Periosteal involucrum will stand out prominently when present, or else the periosteum will show evidences of thickening and often of bone proliferation.

Fig. 5. Subacute osteomyelitis of ulna with thickened involucrum.

The appearance of the periosteum will often suggest the length of time the disease has been in progress and furnish an important factor in the clinical data (Figs. 4 and 5).

In the foregoing I do not wish to imply that the radiograph offers an infallible guide to a differential diagnosis of the several bone conditions discussed. If, however, the radiograph be properly interpreted, it will often cast a flood of light upon the pathological condition, even though other diagnostic methods fail utterly to disclose the true nature of the lesion.

18 East Sixtieth Street.

Medicopsychological Association.—The sixtieth annual meeting of this society (formerly known as the "Association of Medical Superintendents of American Institutions for the Insane") will be held at the Planters' Hotel, St. Louis, on May 30 and 31, and June 1, under the presidency of Dr. A. E. Macdonald of New York City. The secretary is Dr. C. B. Burr of Flint, Mich. The program announces the titles of twenty papers promised for the meeting.

THE TREATMENT OF EPIDEMIC CEREBRO-SPINAL MENINGITIS BY INTRASPINAL ANTISEPTIC INJECTIONS.

By CHARLES E. NAMMACK, M.D.,
NEW YORK.

VISITING PHYSICIAN TO BELLEVUE HOSPITAL, NEW YORK; PROFESSOR OF CLINICAL MEDICINE, CORNELL UNIVERSITY MEDICAL COLLEGE.

THE first twenty-seven cases of cerebrospinal meningitis admitted to Bellevue Hospital during the present epidemic yielded twenty-four deaths, or 90 per cent. mortality. This appalling death rate made the visiting physicians anxious to try any method of treatment which promised better results. In the *Lancet* of November 1, 1902, Seager published an account of what he had witnessed in Lisbon during an epidemic there. In the beginning of the Lisbon epidemic, treatment by hot baths and ice to the head gave a mortality of 60 per cent. Then simple puncture of the spinal canal was tried in twenty cases. Of these, nine patients died. Of the eleven who recovered, one was deaf, one had persistent paralysis of the left arm, and four had bed-sores. The next seven cases were treated by puncture and removal of the fluid and an injection of oxycyanide of mercury. Of these seven, four died. The treatment by lumbar puncture, aspiration of the exudate, and injection of lysol in 1 per cent. solution was then adopted. Of thirty-one cases submitted to this treatment, thirteen died, and the eighteen who recovered were completely cured.[7]

At a stated meeting of the Section on Medicine of the New York Academy of Medicine, Dr. Morris Manges gave the detailed histories of three cases which had recovered under the lysol treatment.[8]

Considering that the mortality in different epidemics of cerebrospinal meningitis has varied from 20 per cent. to 75 per cent., it is very difficult to draw conclusions from any treatment. A régime in which we may take great pride during one winter's experience with any infectious disease, may ride us to a bad fall in succeeding years. A post-mortem study of the brain and spinal cord of a fatal case of spotted fever will also make one skeptical of the value of any alleged specific. And when we read[1] of nine consecutive cases of this disease recovering, without defect of special senses, under inunctions with an ointment containing an organic silver salt, "not begun until grave symptoms appeared," we can only regret that the author's delightful therapeutic optimism is not as infectious as the disease under consideration. Netter's[2] seven cases of recovery, only five complete, however, under repeated lumbar punctures and baths at a temperature of 100° to 104° given for twenty or thirty minutes every third or fourth hour, night and day, make a more rational appeal to our understanding. The value of repeated lumbar punctures has also been emphasized by Koplik.[3] Bela Angyan believes Quincke's puncture to be a rational method, but confines his own treatment to the use of the ice-bag and the subcutaneous injections of bichloride of mercury, made daily along the course of the spinal column.[4] He reports 70 per cent. recoveries in twenty-seven cases under this régime. Wentworth is quoted by Osler[5] as never having seen any cases benefited by lumbar punctures, though constantly on the watch for them. Osler[5] himself speaks of benefit as being possible by withdrawal of cerebrospinal fluid, and thinks that in certain severe cases laminectomy and drainage would be justifiable.

In estimating the possibility of beneficial results from intraspinal injections of lysol, we must consider what lysol is, how it may act, and what danger may attend its administration. Lysol, which is obtained by dissolving in fat, and subsequently purifying with the addition of alcohol, the fraction of tar oil which boils between 190° and 200° C., is a brown, oily-looking, clear fluid, with a feebly aromatic, creosote-like odor. It is said to be five times greater in antiseptic power than carbolic acid, and eight times less poisonous. Gerlach[6] of Wiesbaden found that 2½ per cent. solutions of lysol diminished the growth upon gelatin of spores of anthrax bacillus in one hour, up to complete arrest of growth in six hours. Much weaker solutions arrested the growth of staphylococcus pyogenes aureus in fifteen minutes. Five per cent. solutions of lysol reduced the number of colonies in decomposing fluids from about 300 in 30 minutes, to 50 in one hour, and to zero in 6 hours. Lysol might then reasonably be expected to inhibit the growth of pathogenic micro-organisms in the exudate of cerebrospinal meningitis, and the clinical proof of this was furnished by the published report of the results in the Lisbon epidemic.[7]

That lysol is reasonably safe, even in much stronger solutions than had been employed in Lisbon, is also evident from its extensive employment in gynecological and obstetrical practice where the chances for its absorption from broken surfaces are very favorable. G. Burgl, in the *Münchener medizinische Wochenschrift*,[8] gives two cases in which young children were fatally poisoned by teaspoonful doses of lysol, given internally by mistake. Burgl also collects 16 other cases of lysol poisoning from the literature. Of these 18 cases, 13 were produced by internal administration, of which 7 recovered and 6 died; 5 by external application, of which 2 recovered and 3 died. The largest internal dose which was followed by recovery was 60 grams in an adult, and 25 grams in a four-year-old child.

My own experience with the lysol treatment comprises the following cases:

CASE I.—Italian boy, seventeen years old. Admitted April 12 in delirious condition with history of sickness lasting four days and beginning with chill and severe headache. Examination showed marked retraction of the head, thighs and legs flexed, Kernig's sign present, opisthotonus when rolled over, slight nystagmus, herpes on lips, tongue dry, brown, and fissured, teeth covered with sordes, no cardiac murmurs, no pneumonia, superficial and deep reflexes exaggerated, tache cerebrale present, urine shows a trace of albumin, leucocyte count, 38,600, catheter necessary. Lumbar puncture was made and purulent fluid withdrawn, which gave pure cultures of the diplococcus intra-cellularis meningitides. After drainage 15 c.c. of 10 per cent. lysol solution was injected. The strength of this solution was due to an error, but so marked an amelioration of the symptoms followed the injection, and that without any evidences of lysol poisoning, that in subsequent cases the 10 per cent. solution was also employed. It must be remembered that all the cases were in adults. At the end of forty-eight hours the symptoms had again increased in severity, and a second injection of 15 c.c. of 10 per cent. solution was made. Again the symptoms seemed to be held in check, for a period of forty-eight hours, when a third injection of same amount and strength was made, with apparently a similar result. Three days now elapsed before a fourth injection was thought to be necessary, and after this, patient continued to improve steadily and left the hospital on May 5, 1904, well, except for left sciatic neuritis.

Was this a case showing the remissions common to this disease, or did lysol influence the result?

CASE II.—Englishman, forty years old, always a hard drinker, had syphilis sixteen years ago, had lost about thirty-five pounds in last five months. On

pril 16 was taken with sharp, shooting pain in the ft thigh, which radiated down to the ankle. Walked to a hospital three days later with a temperature 104°, pulse 92, respiration 24, leucocyte count ,,200, and pneumonia in left lower lobe. He also id a mitral systolic murmur transmitted to the left, id intense pain on pressure along left sciatic nerve. x days later the pneumonia defervesced. On the nth day there was a recrudescence of fever to)5°, leucocyte count increased to 34,400, patient ecame delirious, neck stiff and tender, eyeballs eviated, Kernig's sign present. Lumbar puncture ithdrew turbid fluid, which yielded pure culture of ie Weichselbaum organism. The puncture was llowed by injection of 15 c.c. of 10 per cent. lysol lution. Patient grew steadily worse and died on ie thirteenth day. Autopsy showed purulent erebrospinal meningitis, recent ulcerative endoarditis, old fibroid endocarditis, and hydronephrosis f right kidney with a few small calculi in the dilated alices. This was manifestly a case in which little ould be hoped for, with any treatment, because of he complications.

Case III.—Canadian machinist, thirty years old, rought in by ambulance April 21, in unconscious ondition, with history of twenty-four hours' illness.)n admission, temperature 105°, pulse 60, respiraion 28, pupils dilated, eyeballs roll from side to side few circular rose-colored spots on trunk and highs, Kernig's sign elicited, no heart murmurs, no neumonia, albuminuria slight, leucocyte count 17,000 and rose to 49,600 in forty-two hours. Lumar puncture withdrew only 5 c.c. of clear fluid, which showed diplococcus meningitis in pure culture. Injection of 15 c.c. of 10 per cent. lysol solution was made. Patient totally unconscious. Next day was able to answer questions when aroused, but relapsed into stupor immediately. Died sixty-seven hours after admission. Autopsy showed no complications, the curator's verdict being "epidemic cerebrospinal meningitis characterized by surprisingly slight indications of general sepsis." No perceptible effect from lysol.

Case IV.—Hungarian stonecutter, twenty-eight years old. Admitted April 28 with temperature of 106°, pulse 120, respirations 40. No previous history obtainable. Examination showed an erythematous mottling on chest and legs, left internal strabismus, heart enlarged with rough, harsh, systolic mitral murmur transmitted to posterior axillary line, pneumonia of right lower lobe, abundant albuminuria and granular casts, leucocyte count 22,600. Lumbar puncture withdrew 22 drachms of slightly turbid fluid, which showed diplococcus meningitides in pure culture; 15 c.c. of 10 per cent. lysol solution was then injected into spinal canal. Patient seemed to rest more easily after lumbar puncture, but temperature next day rose to 107.6°, and patient died thirty-eight hours after admission. Autopsy was refused, but complicating cause of death was probably malignant endocarditis.

Case V.—Irish laborer, twenty-four years old, occasional drinker, epileptic since eleventh year with grand mal attacks about once a week. Admitted April 25, with history of chill, vomiting, progressively increasing headache, and stiff neck for past four days. On admission temperature 100.8°, pulse 100, respirations 24, intense rigidity and retraction of neck, eyes negative, no skin rash, thighs and legs flexed, Kernig's sign on both sides, knee-jerks absent, no heart murmurs, no pneumonia, but abundant coarse moist râles and impaired percussion resonance over both lungs, leucocyte count 15,200, catheter necessary. Lumbar puncture withdrew clear fluid, which did not show characteristic Weichselbaum diplococcus, but an organism which was probably staphylococcus. Ten c.c. of 10 per cent. lysol was injected, after which patient became very restless and noisy for about twenty-four hours, when delirium ceased and he became rational. Second lumbar puncture was made, no fluid obtained, but a second lysol injection of 10 c.c. of 10 per cent. solution was given. Some loss of sensation in both legs at this time and right foot-drop. Catheter was necessary for nineteen days. The epileptic attacks ceased during the course of the cerebrospinal fever. Progress was apparently toward recovery until the thirtieth day in hospital, when he relapsed into coma, and died. Autopsy showed characteristic changes of acute cerebrospinal meningitis, complicated by old gonorrhœal purulent infection of entire genito-urinary tract.

MYOCARDIAL CHANGE FROM THE CLINICAL SIDE.*

By JOHN W. BOYCE, M.D.,
PITTSBURG, PA.

Myocardial change has been chosen for discussion because it is a subject which has in every way received but an insignificant fraction of the medical thought and teaching to which it is entitled. It is undoubtedly the fact that medical lecturers tend ever toward the subjects that are easy to teach, rather than toward those that are important to learn.

Now, in all medicine there is perhaps no subject so exactly worked out, so susceptible of embodiment in clean-cut, dogmatic statement, as disease of the endocardium, its immediate and remote effects. The subject of endocardial lesions occupies voluminous monographs. Allbutt's excellent system of medicine, covering nearly 10,000 pages, gives to the subject of myocardial change only 23 pages and these 23 are divided among 33 different varieties of myocardial trouble. This tendency of the professor is ingrained in the student until many a practitioner is ready to institute treatment merely because he has heard a murmur; and the statement from his lips—"the heart is normal"—means that he has listened to it and heard no murmur. Now it can be shown that a loud murmur, betokening a considerable defect in the valvular mechanism, may be heard over a heart that is for all the purposes of life and activity an entirely normal heart, and that a valvular defect is chiefly of importance as warning us that either by direct action of the original cases of endocardial trouble, or by the increased work entailed by fault in mechanism, the myocardium is apt to suffer relative or absolute insufficiency.

To illustrate the contention as to the unimportance of valvular lesion in the presence of a normal myocardium, let me cite the following three cases from private practice:

Geo. R., policeman, presiding over a crowded corner with dignified activity, undisturbed by any

*Read at the meeting of the Pittsburg Academy of Medicine, March 8, 1904.

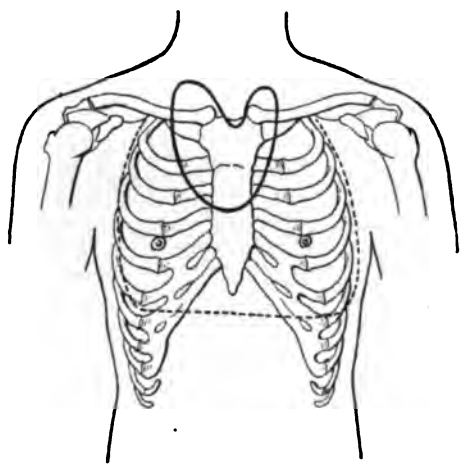
consciousness that he is a pathological curiosity. He has an aortic regurgitant lesion.

C. W. is a lawyer in active practice and strenuous business. A pet family joke is the heart murmur, for which he was rejected by a life insurance company twelve years ago. He does not in the least suspect the truth—namely, that he really has it.

Charlotte W. has in the last four years born three children in absolute defiance of the doctor's orders. After each confinement, she has had an attack of acute endocarditis, temporarily augmenting her pre-existing murmur. No attack has lasted more than a few days—the pain, fever, and detention in bed were such as the old women were quite ready to attribute to "milk fever." Aside from these she has not had a day's sickness; in all the four years she has not had a pain, an ache, or a mild discomfort that could be fairly attributed to her heart lesion. In consultation practice such cases are, of course, absolutely more frequent, though perhaps not relatively so.

Take the case of Walter B., who comes seeking advice (having marriage prospective in his eye) because of the spitting of blood. The blood is easily seen to come from a congested pharynx, which proves readily amenable to local treatment. In the physical examination a considerable mitral regurgitation is found. Of its origin, nothing can be learned. Eleven years ago, when, at the age of seventeen, he applied for appointment to Annapolis, the murmur was loud and plain. It doubtless remained so during the four years he spent at a State university, playing on the foot-ball team with satisfaction to himself and renown to his alma mater, and it will doubtless remain loud and plain until the day he dies—of old age be it hoped.

That these innocuous murmurs are not slight and doubtful ones, that they really arise in an imperfect



endocardium and not in a hyperæsthetic examining ear, let the following case attest:

O. R. seeks advice as to the desirability of continuing a rather strenuous game of tennis. In an examination for life insurance, the tracing of which the illustration is a copy, was made. The dotted line marks out the area of audibility; the solid one, the area of greatest intensity. Of the origin of the murmur, nothing was known. Compensation was perfect. The subject continued through the autumn to play tennis in his usual tournament form.

If it be objected, as it well may, that these are but fragments of cases—that any one of the patients may yet show typical symptoms of loss of compensation, hear the ending of such a case.

H. P. was an aged Jewess. She said she was eighty-three; her grand-nephew with whom she lived, said she had been that age for ten years to his certain knowledge, and her appearance supported his statement. She had at the apex, a harsh systolic murmur—it had all the characteristics of an organic lesion, and I believe that the blood did, in fact, spout backward through the mitral valve at each systole.

First seen in February of 1902, an absolutely unfavorable prognosis was given, two weeks being mentioned as a probable duration of life. The patient died in September of last year. Mark that there was not in any member of this generation the remembrance of the time when this murmur was acquired, or of the date when she first had it. Mark also that her death was without sign of loss of compensation. When her time was come, she died typically of senile dementia, and the omnipotent digitalis could not prolong her life one day.

Such cases might be multiplied indefinitely. The larger life insurance companies see enough of them to calculate an average expectation of life, and to offer insurance on moderate terms.

Let us turn our attention to those conditions that reside in the myocardium itself, destroying its contractile power and allowing the valvular leak to turn the balance of health adversely. Clinical study is necessarily based on broader divisions than is pathological. For the morbid anatomist, each of the thirty or more varieties of cardiac myopathy has its interest, and scientific importance. From the clinical standpoint, it is to be said that most of them are absolutely indistinguishable one from the other; that some produce no visible consequence, while others are so rare that they bear about the same relation to practical medicine that dime-museum freaks do to the progress of civilization. Well for the physician if he can say that there is or is not an organic disease destroying the normal contractile tissue of the heart. The presence of such condition being established, it is usually possible to guess with a certain degree of plausibility whether the condition be one of fatty degeneration, of fibroid heart, or of sclerosis of the coronary arteries. The latter distinction is of some importance in treatment, though scarcely in prognosis.

Acute myocardial change, whether degenerative or inflammatory, seldom appears as a sole cause of death. When it does, it is apt to escape recognition from the anomalous nature of its symptoms. Let me repeat the words in which Latham, first among the moderns, records an observed case.

"A boy, twelve years of age, was in perfect health on Saturday night and dead on the following Tuesday afternoon at two o'clock. He had, in the opinion of all who saw him, the severest inflammation of the brain. The attack was sudden with great heat and frequency of pulse. He had delirium and convulsions, and pointed to his forehead as the seat of the pain. At length he sank into a state of insensibility and died. Upon dissection, not a vestige of disease was found within the cranium, but the heart was the seat of the most intense inflammation, pervading both the pericardium and the muscular substance. When the heart itself was divided, the muscular fibers were dark-colored almost to blackness, loaded with blood, soft and loose of texture, easily separated and easily torn by the fingers; and at the cut edges of both ventricles small quantities of dark-colored pus were seen among the muscular fibers."

Fortunately the majority of cases occur in the course of a few diseases in which, examination of the heart being usually a routine measure, we are less apt to be lead astray by anomalous or referred symptoms. First and foremost stands acute articular rheumatism. If the symptoms be in any direction out of proportion to the joint involvement, attention is at once directed to the heart. When a harsh murmur is heard, showing disease of endo- or pericardial

rface, it masks the sign of myocarditis, but a cer-
in complication with the later condition is always
be assumed. What its proportionate importance
ay be, is one of the most delicate questions our art
esents. Occasionally, in the absence of any mur-
ur, the disturbed rate and the unsatisfactory char-
ter of the pulse, the distance, or the muffling, per-
ps the reduplication, or the galop rhythm of the
art sounds, leads to a diagnosis of uncomplicated
yocarditis, and the end will only too often confirm
r fears.

Along with rheumatism, it is usual to mention
arlatina as a cause of myocardial damage. This I
n disposed to dispute on purely theoretical grounds.
y experience in the pathology of scarlatina is nil.
ut clinical study has shown that if the patient has
ne of the more definitely recognizable complica-
ns, he will recover, save in those instances in which
: is engulfed by an overmastering infection. There
is never been occasion to attribute a fatal ending
an untoward course to any heart complication.
urther, I find that in life insurance examinations,
here we have to do exclusively with innocuous and
nsuspected murmurs, the origin is to be attributed
) scarlatina in a much larger percentage than in
inical work. From which it seems fair to assume
at the scarlet infection touches the heart with
arring finger but superficially, leaving its imprint
n endo- and pericardium, but passing the myo-
rdium by.

Pneumonia also occurs to the mind from its asso-
iation with cardiac insufficiency. Be it noted, how-
ver, that the young and vigorous do not in the
ourse of pneumonia, suffer the much-dreaded heart
ilure. It occurs in the old, in the feeble, in the
issipated. In other words, it is not the develop-
ent of a new acute degeneration, but the manifes-
tion under special stress of an old chronic one.

Before the days of antitoxin, diphtheria gave fre-
uent opportunity of studying an acute degenera-
ive process. The complication was plainly declared
y a slow pulse, soft or even gaseous; on any slight
xertion, becoming very rapid, very small, very
eble. The heart sounds were found muffled and
nequal, fetal in character, or perhaps reduplicated
nto the galop rhythm. Such cases were seldom
verlooked, but often attributed to disturbed inner-
ation rather than to the grave organic cause actu-
lly present.

Such acute conditions are seldom in themselves a
ause of death. They are to be thought of as con-
ributing to the pathology and clinical picture in all
cute infections, but particularly rheumatism, diph-
heria, pneumonia, typhoid fever, and septicæmia.
They are also to be remembered as the usual starting-
oint of chronic conditions. So that in the diagnosis
f the latter, a previous history of any of these infec-
ions is of the utmost importance. Chronic myo-
ardial change, whether it be fatty, fibroid, or ather-
matous in character, is declared to the patient, by
nany varying symptoms. Pain is usually present.
It varies from typical angina pectoris through angi-
oid pain of various degrees to a mere sense of
ppression back of the sternum. Often it is located
ufficiently low in the chest to be mistaken for stom-
ch pain, and numerous sudden deaths are attributed
o acute indigestion. Dyspnœa and palpitation,
ccurring especially on exertion, are common to
these as to all other cardiac affections. The curious
affection first noted by Dr. Stokes of Dublin, consist-
ing of pseudo-apoplectic attacks, is one rather rare
manifestation; Cheyne-Stokes' breathing is another.
Regard to reasonable time limits prevents their con-
sideration to-day.

"Almost as common as pain or dyspnœa is a peculiar loss of vitality and strength [I quote now from Dr. Stengel], which characterizes most of the cases of progressive myocardial degeneration. This is so gradual in its development that it is more often ascribed to increasing cares and to advancing years than to the real cause. Most of the patients suffering with the disease under consideration are above middle age. The more pronounced instances occur in the men who have led active business lives, and who have subjected themselves to repeated or continuous strains. When we see in such persons a falling off in activity, a disposition to be less interested in affairs, a loss of strength of a purely physical kind, especially when the individual shows some loss of color, a premature grayness of the hair, and that peculiar yellowish-whiteness of the face, combined with slight injection of the venules, which is so characteristic of atheroma as to be called the atheromatous facies, we are justified in suspecting a deep-seated, vital, morbid process and should not overlook the heart as a frequent seat."

It is evident that diagnosis will most often involve the discrimination of purely nervous affection. In this regard the personal and family history is often of the utmost value. The question arises in middle life or after. The neuropath will have shown many previous indications of his tendencies. The cardiopath, on the other hand, tells a story of sane and useful, though perhaps excessive, activities. He was an athlete in youth; a man of affairs after maturity. He has suffered from rheumatism in some of its protean forms—from diphtheria, pneumonia, or syphilis. Never a slave to any vicious habit, he has worshipped with right good will in Dr Dacosta's favorite metaphor—at the shrine of Venus, Bacchus, and Vulcan. He comes of a line of men, hard livers perhaps—but always sane and forceful, dying at ripe ages, of apoplexy, interstitial nephritis, gallstones, gout, or possibly enlarged prostrate. The neuropath gives a family history of epilepsy, of insanity, of alcoholic or other drug addiction, and the like. In the common case of mixed, rather than of uniform and consistent heredity, it is often useful to inquire whether the subject most resembles the paternal or the maternal line.

Physical examination is of more absolute value than either symptoms or history. Yet it is always to be read strictly in conjunction with them. No single sign is in itself of final importance, but each acquires force from its association with another. First of all is a certain characteristic physiognomy, exceedingly difficult to describe, and apt in itself to lead to ludicrous error. It has so often suggested the line of investigation that lead to a correct conclusion that its existence cannot be denied. A certain pallor, which is rather low-toned gray than white, an inelastic skin, smooth and soft to the touch, and showing a tendency to remain when pinched up in folds; a look of anxiety and weariness, which the patient endeavors to contradict by tone and manner, seem to me to be elements. Premature grayness of the hair, when not accounted for by heredity or by excessive mental strain, is of some value. In the pulse, size and tension are of more importance than rate or rhythm. Irregularity or intermittence often marks the action of the fibroid heart. Be it remarked in passing that such cases are of relatively favorable prognosis. A very slow pulse of low tension is of great value—which is much increased if it is found that change of position, or slight exertion alter its rate unduly. Inspection of the chest shows the apex impulse broad but feeble. That the beat is seen more readily than felt, is very significant. Percussion

may or may not show the heart enlarged. If the enlargement be great, there is some complicating condition. The heart tones lack quality. The short, firm boom of the normal first sound becomes flat and prolonged. Rhythm is much altered—intermittence, unevenness, doubling of the first sound at the apex, galop rhythm, or the fetal character may be noted. Not infrequently we can gratify our passion for a murmur, even in a purely myocardial case. It is invariably mitral in seat and regurgitant in character. For consider how the closure of the mitral valve is not pure mechanism, as in the aortic, but a matter of complicated physiology. Any seamstress can take of mackintosh cloth what will suffice and construct a very fair set of semi-lunar valves. If they could be set in place, they would prove fairly efficient. In the mitral valve the case is quite different, even if we ignore the doctrine of a sphincteric action of the fibers surrounding the auriculoventricular opening. It is evident that the holding in one flat plane of all portions of the mitral leaflets depends upon a delicate coördination between the papillary muscles, and the general diminution in size of the cavity of the ventricle. So in purely muscular affections we have blood leaking backward into the auricle, with a soft rushing sound. One likes to think that this murmur is distinguishable by the ear alone from one set up by a sclerotic valve. But accurate diagnosis is perhaps better based on a general impression of the totality of the case, rather than any particular character in the murmur.

Finally it is to be said a trace of albumin frequently comes and goes in the urine, most often without the association of tube casts.

All these points may be illustrated in a brief outline of three cases:

W. H. was seen in the winter of 1901. He desired confirmation of a comforting, though uncomplimentary opinion given by his family physician. His complaint was of vague fears, of lack of energy, of irritability when called on for exertion—in short, of laxation of all the fibers of his soul. He attributed his symptoms all to neurasthenia. But he was disturbed by the fact that his physician had, in two examinations out of many, found slight albuminuria without tube casts. On the occasion when I saw him his urine was of average specific gravity, and entirely normal. At forty-eight years of age his hair was quite gray. This he said was contrary to the habit of his family, and had appeared in the last three years. Sharper inquiry brought out the fact that the loss of his accustomed energy had been noted by others before the patient. His personal and family history was that of good nervous balance. Of all of his relatives, I could not hear of one neurotic subject. Nor was there any sufficient cause for neurasthenia. He had indulged in the usual athletic sports of youth vigorously, perhaps excessively. His manhood had been that of a prosperous and busy merchant in a country town. He had been infected with syphilis, had made a good recovery, and had persisted in treatment for a proper period. He had drunk freely, but not constantly, and never to drunkenness. With the physical examination of the chest, we at once touched firm ground. The pulse was 56 to the minute, very low in tension, and dropping a beat at long intervals. After moderate exercise, it jumped to 100 and more, and was very feeble. The heart was enlarged a good two fingers' breadth. The heart tones were distant and feeble, in proportion to the pulse tension, and sounded like the ticking of a watch. This man had already been advised to keep away from the doctor's, to forget his complaints, and to indulge in active out-of-door life. It is conceivable that if he had had the murmur before spoken of, he might have been put on digitalis, and the dose increased with the unfavorable progress of the case.

H. R. an applicant for life insurance, was a Jew of spare frame. His pulse beat about 52 to the minute. Now a very slow pulse is rather frequent among men of his race, and is of itself without pathological significance. But such a slow pulse should be of something more than medium size, and of at least firm tension.

This pulse was smaller than is the pulse of a strong man when fever has lashed it beyond 110; it was notably soft. The heart was not enlarged. The heart sounds were distinct. The first had lost its booming character; it sounded more like a scrape. In three successive urinary examinations the specific gravity was found uniformly low. This I take to be a case of fibroid heart. He positively denied all symptoms. It is probable that a laborious occupation would develop anginoid pains, and perhaps ultimately rupture the heart. In his present sedentary occupation, he is likely to live past middle life, but he would certainly not survive the accident of any acute infection, particularly the pneumonic.

Mary H., was admitted to D ward of the West Penn Hospital in September, 1903, as a case of gastritis, because of vomiting and gastric pain, and as a case of gastritis she was reported to me by the resident physician. An indefinable something in her face led me to say to him, "Examine that heart again, doctor." On my next visit a heart murmur was reported, her pain was said to be located behind the sternum, and I found that the patient had been put on digitalis. Now the woman had none of the symptoms that we associate with loss of compensation. There was no dropsy, and no sign of general passive congestion. She admitted that for two or three years there had been some difficulty about physical exertion, particularly the climbing of stairs, but the difficulty was not dyspnœic in character. She seemed to think that rather the will than the strength was lacking. Her pulse was rapid and excessively soft in character. In spite of some fat and considerable mammary development, it was possible to determine that the heart was enlarged. At the apex and round toward the axilla was a soft systolic murmur. The second pulmonary sound was slightly accentuated. It seemed certain that there was actual leaking through the mitral valve, but the opinion was hazarded that this was a fatty heart, and the murmur one of relaxation. As a matter of fact, with rest in bed, concentrated nourishment, and the administration of strychnine, the tone of the circulation improved—the murmur disappeared. The subsequent history of such a case will not be long. She may reappear in a few years or a few months with a large dilated heart, indistinguishable from the late and hopeless stage of uncompensated valve lesion. She may have again the severe pain at the lower end of the sternum, suggestive of stomach trouble and so die unexpectedly of acute indigestion. A pneumonia would snuff out her life before any strange physician, summoned on the instant, would have time to formulate a diagnosis. If she had wealth enough to command the acme of physical comfort, climate, rest, and attendance, it might purchase for her the doubtful advantage of an idle, worried existence through many years.

Such is cardiac myopathy as we see it at the bedside and in the consulting room. These cases are not rare. While diagnostic principles seem vague, it is possible by attention to the whole aspect of the case to establish an opinion important for treatment and still more so for prognosis. More important still

will exact knowledge of the symptoms and signs of such cases prove when we try to analyze the etiological basis of the circulatory weakness that appears as the most important clinical fact of almost every acute infection.

430 PARK BUILDING.

THE USE OF RUBBER TISSUE AND BORACIC ACID IN THE TREATMENT OF SURFACE GRANULATING WOUNDS AND ESPECIALLY OF THE VARICOSE ULCERS OF THE LEG.

BY W. SCOTT SCHLEY, M.D.,
NEW YORK.
SURGEON TRINITY HOSPITAL; ASSISTANT SURGEON ST. LUKE'S HOSPITAL.

DURING the last year we have been employing rubber tissue in the surgical work in the Out-door Department at St. Luke's Hospital for a variety of purposes where formerly gauze was used. This more extended use has resulted from observation upon its rather remarkable action in the healing of the ordinary granulating varicose ulcers of the leg, for the treatment of which this method was first suggested to me by Dr. Abbe.

The subject of the treatment of those more or less broad surface granulations and benign ulcers from various causes and in various situations, has occupied space in medical literature from ancient times. It is not the purpose of this paper to extensively review the many methods of treatment

FIG. 1. Showing extent of overlapping of the rubber tissue.

with which nearly every one is familiar. The broad ulcers from a burn, the varicose ulcers of the leg, and the soft flabby granulations in ulcers, resulting from tubercular inflammation, and seen so frequently in the neck and above and below the clavicle, are of every-day experience. The chronicity, pain and discomforts of these conditions are worthy of our best efforts at relief.

We have usually been satisfied to apply a wet dressing with supportive bandage to relieve redness, heat and induration, and later to apply various lotions, powders, ointments, and strapping. Healing finally occurs, but slowly, and skin grafting or more radical procedures are not infrequently called in to complete the cure.

Among the various procedures of the last few years the following are of interest: Levy (*Vratch*, August 26, 1900) reports three cases of leg ulcer

FIG. 2. Application of rubber tissue over area of ulceration.

treated by circular incision, the method of Nussbaum proposed in 1873, consisting of incision around the ulcer to the deep fascia and a finger's breadth from its edges. Brault (*Gazette des hôpitaux*, No. 89, *Centralblatt für Chirurgie*, October 31, 1903), in various leg ulcers, is still using another modification of the method of Moreschi proposed in 1894, and subsequently modified by Mariani, Vince, Mauclaire, and others; an attempt at the radical cure by incisions about the limb above and below the ulcer extending to the deep fascia and cutting all structures, with the object of relieving hydrostatic pressure and stasis in the ulcerated area. Healing in from fifteen to twenty days is claimed. The method has generally been abandoned. Acqua (*Riforma Medica*, October, 1903) reports eight cases treated by this method, and concludes that it does not interrupt communication between the superficial and deep circulation, nor offer impediment to new collateral ways. Recurrence is the rule. Wagner (*Centralblatt für Chirurgie*, December 12, 1903) advocates a plan of treatment by the open method, exposure of granulating areas to the drying influence of the air which checks the exuberant granulation. At night a drying powder is used and the parts bandaged. The method was considered especially useful in unsuccessful or partially successful skin grafting, or where that procedure had been refused. His method appears to be the revival of an older procedure in which the ulcer was exposed to the air under a wire protective netting or basket, a bandage being applied over all. Bukovsky has attempted to use the toxins of various bacteria isolated from leg ulcers in their treatment. Dilutions of the cultures upon compresses were applied to the ulcers two or

three times a day, the patients remaining in bed. Kindler (*Centralblatt für Chirurgie*, No. 10, 1900) has used hot water upon chronic leg ulcers with good results. About three and a half pints of very hot water is allowed to fall on the ulcer from a height of six feet. This is repeated two or three times a day and is followed by dry rubbing with iodoform and dermatal. Meitner (*Frauenarst*, Vol. 18, 1903) lays stress upon bandaging in the ambulatory treatment of leg ulcers. He uses various ointments and powders and speaks of the

FIG. 3. Absorbent gauze in position over tissue—roller bandage securing dressing. The gauze is turned back to show the rubber tissue beneath.

occasional use of dilute alcohol. Schiller (*International Journal of Surgery*, November, 1902) has had good results from the use of europhen and protargol thickly applied to ulcers, which are then covered with Unna's zinc gelatin. Healing resulted in from six to seven weeks. Fischkin (*Medical Standard*, September, 1903) in leg ulcers has recommended the use of gutta percha paper (tissue) for delayed epidermization. He thought that it served the purpose of draining, removing secretion, and also preventing adhesions between dressings and the surface of the ulcer. His suggestion was first to paint the base of the granulating ulcer with a 2 to 4 per cent. solution of silver nitrate, then dust with bismuth, dermatol or ichthyoform and cover with the tissue.

The method of which I wish particularly to speak is as follows: Upon these freely granulating surfaces well-powdered boracic acid is abundantly sprinkled. This is covered smoothly with rubber tissue, overlapping the edges of the ulcer by an inch or two (fig. 1) and held in place by adhesive plaster strapping (fig. 2). Absorbent gauze covers the tissue, again overlapping its edges, and a snug supporting bandage completes the dressing (fig. 3).

A point of much importance is the length of time such dressings should be left undisturbed. They are rarely changed oftener than once in five days, usually once a week, and occasionally the interval is longer. I have been impressed with the really rapid rate of epithelial growth if given a chance. The irregular surface or mesh of the gauze "crocks" the surface, producing hills and dales over which epithelium has to climb. The smooth surface of the tissue insures a smooth surface to the granulations. The boric acid acts as an efficient antiseptic astringent, diminishing and sweetening the discharges and preventing excessive transudation and exuberant granulation, which two factors undoubtedly act as the greatest checks to epithelial growth and covering. These factors, undoubtedly long appreciated, have led to the use of drying powders and various expedients to reduce excessive granulation, but, while doing so to a certain degree, form a crust under which exudation continues as before. It remains to combine the mild antiseptic astringent with a smooth impervious surface to secure the best results.

Often, upon the careful removing of this dressing, very little will appear to have been done, the surface appears generally moist, and the red but flattened granulations seem uncovered. It is wise to refrain from touching this surface, for if we wait a few moments and allow it to dry, which in winter indoors rapidly occurs, a marked and very pretty differentiation of the parts covered and uncovered by epithelium will appear; the covered part appearing dry, smooth, and slightly glazed and paler, the uncovered relatively moist and red, as granulation tissue. Every one is familiar with a somewhat similar phenomenon with skin grafts that appear

FIG. 4. A type of ulcer suitable for treatment with boracic acid and rubber tissue.

to have failed. Several times a wet, perfectly transparent and most delicate epithelial covering has been removed before realizing that the surface of the ulcer could possibly have been so extensively epidermized.

Upon soft, freely granulating surfaces, such as one often sees upon burned areas, and in the varicose ulcers of the leg, this method of combining boric

cid and rubber tissue has given us a rapidity of ealing which in many cases has seemed incredible.

Within the last few months we have extended his method of treatment to a number of ulcers, he result of tuberculous inflammation, with the haracteristic flabby granulations and undermined luish edges, and in which a certain amount of tuberular tissue appears to be present. Here also very ratifying results have been shown. One of these ases, shown in figure 5, presented an area of such a haracter. A noteworthy improvement appeared n this case after the third dressing; granulations were firmer, the edges appeared no longer undernined, and the general area contracted. The transudation being rather more free from these surfaces, hey seem to require a somewhat larger application of the powder and at intervals of but three to four days between dressings.

In second degree burns equal parts of a 10-per-cent. boric-acid ointment and zinc-oxide ointment under rubber tissue is a combination particularly useful and grateful. It may be applied directly to the area uncovered by the removal of blebs and bullæ. I find this use of rubber tissue in burns has

5. Ulcer, the result of tuberculous inflammation (after three s), granulations flattened, edges attached, and epithelium in.

been recommended by Dr. G. Tucker Smith, N. (*American Journal of the Medical Sciences*, , 1903).

e impermeability of the rubber tissue further sted its use as a covering for ointments in- of gauze which absorbs the larger bulk of the , leaving a small dried residue to act upon the . We have had results that indicate a better ion and a superiority of penetration through the unbroken skin.

The use of the 1 in 8 guaiacol, lanolin, and lard preparation, under the tissue, in many cases of tubercular glands of the neck (proven tuberculous by the removal of one or more glands), several tubercular wrists, and one tubercular shoulder (all checked by radiographs), combined, of course, with the usual immobilization in the cases of joints, has led to subsidence of the trouble more frequently, more quickly, and to a greater degree than formerly when we were employing gauze, or the ointment was simply painted on, or very lightly rubbed in. The subsidence of (non-specific) glandular swellings, indurations following inflammation and trauma, etc., has been more rapid and satisfactory with an ichthyol or iodine ointment under rubber tissue than with gauze or absorbable material.

Occasionally mild skin irritation is caused by the guaiacol or too strong ichthyol. A dilution of the ointment or the use of a simple zinc oxide for a few days has always sufficed to remove this, when the treatment can be resumed.

In the use of boracic acid the possibility of absorption and resulting poisoning is to be remembered. So far we have encountered no such results, although it has been used upon surfaces of over thirty square inches. The usual support to the circulation in the shape of a snug bandage seems of advantage, but the reparative process under the tissue appears to run ahead of any help so gained. This appeared in a number of cases in which a start was made by the usual methods and under snug supportive bandaging. After several weeks of slow progress the adoption of the rubber tissue and boracic acid produced such marked results that one could not but ascribe to it a specific action.

When phlebitis, periphlebitis, or broad flat ulcers with green sloughy bases have existed a preliminary treatment with wet dressings, aluminum acetate, 1-100 carbolic acid, creolin, naphthalin, boric, and iodoform gauzes and ointments has been used. (And let me add here that the addition of boracic acid to iodoform gauze or powder in the treatment of abscess and dirty wounds in general, produces results in the cleaning up that iodoform alone is slower in producing.)

Eczemas, after the subsidence of heat and induration under aluminum acetate, have yielded speedily to an ointment composed of $\frac{1}{3}$ or $\frac{1}{4}$ of a 10 per cent. salicylic-acid ointment and $\frac{2}{3}$ or $\frac{3}{4}$ of a zinc oxide ointment.

Careful observation, ingenuity of application and method of securing dressings will, I feel sure, lead to the more extended and general use of rubber tissue and boracic acid in the treatment of certain classes of granulating surfaces, and especially of the varicose ulcers of the leg. Painful and dangerous sores in this latter condition are healed, the cause, of course, is not removed, and circulatory support is necessary.

As with all procedures, different observers will secure different results, but the method herein proposed has given us results that have not been attained with any of the methods heretofore recorded.

The following points are presented for consideration: The combination of boracic acid and rubber tissue is recommended for the rapid epidermization of the broader, exuberantly or freely granulating surfaces.

The dressing is not a dry one, the rubber tissue preventing evaporation. The total wound discharge with the boracic acid is less, but occasionally appears greater, because being somewhat confined it does not, as with the use of gauze, soak the dressings so extensively and become diffused.

The antiseptic, astringent, and sweetening action of boric acid permits of the advantage of infrequent dressings, bacterial growth being inhibited.

Upon flat, firm granulating surfaces this method appears to work well, but not so quickly as with the softer granulating surfaces, but upon either it appears faster than any method other than skin grafting.

It has not been employed as yet upon those ulcers with gangrenous or sloughy bases, or extensively upon those larger indolent ulcers without or with scanty granulating surfaces. Upon some smaller ulcers of this class it has worked very well.

A CASE OF BILHARZIA HÆMATOBIA INFECTION.

By T. N. RAFFERTY M.D.,
AND
H. N. RAFFERTY, M.D.,
ROBINSON, ILL.

In the *Western Medical Reporter* of March 15, 1882, there appeared the report of a case of bilharzia hæmatobia found in southern Illinois, by Dr. David S. Booth, Sr., of Sparta. Up to that time it had been thought that this parasite was to be found only in the Orient, and consequently Dr. Booth's report was the object of much adverse criticism. He described the parasite as bisexual, the male worm showing a distinct gynecophoric canal, which contains the female during copulation. The ova showed a spine from the anterior end; the embryos were flask-shaped and ciliated.

Dr. Booth's patient was a spare woman of twenty-eight years, who complained of vomiting, diarrhœa with pain in the bowels, and difficulty of urination. Her urine was bloody, of acid reaction, of a sp. gr. of 1020, showing a trace of albumin and numerous parasites.

The present observations on bilharzia hæmatobia are based on a case previously reported by Dr. Edwin Walker of Evansville, Ind.* Mrs. R. is of a Jewish family, and was twenty-eight years of age at the beginning of the period of observation, which was from April, 1900, to September, 1901. We will not dwell on her previous history, which was given in Dr. Walker's report, but simply reiterate the fact that the patient's home was in central Illinois, and that she had never lived or journeyed outside of this country, or even in our Southern States.

On April 20, 1900, we examined a specimen of the fluid from a supposed cyst in communication with the urinary bladder, and found a sp. gr. of 1006, a large number of red blood cells, and strings of mucus. In the fresh specimen (Fig. 1) we found one embryo, several ova, and a few parasites. The embryo found was without motion, pear-shaped, and measured 5μ in greatest diameter. Its cilia were distinct but inactive. The ova appeared indefinitely granular and showed amœboid movements. The worms, or parasites proper, were numerous, there being as many as three in the field at one time. They were highly motile, passing among the red blood cells, as a tad-pole among so many pebbles. This motility was retained for twelve hours.

A specimen stained with borax-carmine (Fig. 2) showed numerous ova, ovoid and round in outline, measuring from .16 to .25μ in greatest diameter. They were polynuclear, the nuclei being nicely stained, while the protoplasm was unstained. They were without motion. The parasites did not take the stain, but lost their motility. They showed a distinct canal through their entire length, and were found curled up in various positions, at one place two of them being interlocked. They ranged from 6 to 13μ in length.

A second specimen of this same cystic fluid was examined on April 24, 1900, after the patient had been taking two grains of methylene blue three times a day for three days. A fresh slide showed numerous large embryos with ciliæ inactive. The nuclei were stained with the methylene blue which had been taken internally. A few small ova showing amœboid movements were found. There were numerous parasites stained blue, in all positions but without motion.

Examination of the urine at this date showed a deep indigo-blue color, acid reaction, sp. gr. of 1022, and neither albumin nor sugar.

Journal of the American Medical Association, February 17, 1900.

Microscopically (Fig. 3), numerous embryos and ova were found, the former with flagella and highly motile, the latter showing amœboid movements.

On August 5, 1900, Mrs. R. had an attack of hæmoptysis, followed by a constant hacking cough, with a sputum of blood, mucus, and broken-down lung tissue. On the evening of August 21 she bled to the extent of eight ounces, and about the same on the 22d. These attacks were preceded by a sense of fulness in the chest, with cough and slight dyspnœa. She complained of tenderness over the left lung; and its apex percussion note was somewhat dull. These lung hemorrhages continued in smaller amount almost daily until September 25, and then gradually stopped.

Examination of the blood from the left lung (Fig. 4) showed a large amount of partially disintegrated lung tissue, a beautiful specimen of the alveoli, filled with epithelial débris and exudate, and at some places perfect casts of the medium-sized bronchioles. The distomæ were found, together with their embryos and ova, all three forms corresponding with those previously found in the urine. The parasites were without motion and apparently dead, as were also the embryos; but the ova were very active, at one time appearing round, and at another taking a crescentic shape.

On August 23, 1900, we took blood from the peripheral circulation (finger), stained it with borax-carmine and mounted in balsam (Fig. 5). The red cells were normal in appearance. There was an apparent increase in leucocytes, though no actual

(4 and 5) Parasites (unstained and without motion: 6 to 13 micro-mm long.)

(FIG 3 (Urine after administration of methylene blue.)
(Nuclei stained, after giving methylene blue internally.)
(1 and 2) Embryos, with flagella—highly motile.
(3) Ovum—showed amœboid movements.

nt was made. A large number of distomæ was nd, lifeless, and of a size and shape previously deibed. Neither embryos nor ova were to be found. September 26, or about the time when the bleedfrom the left lung ceased, Mrs. R. had her first intinal hemorrhage, passing several ounces of ght blood with a few small clots. She comined of severe colicky pains over the lower abdon, tenderness, gurgling, and some gaseous distenn. Following this she had many similar attacks, th ten or twelve stools a day. The blood seemed ver to be retained long, and apparently came from low the ileocæcal valve. The patient also vomd some little blood during this period. These disarges from the bowel showed the distomæ, emyos and ova: also blood and epithelial cells (Fig. 6).

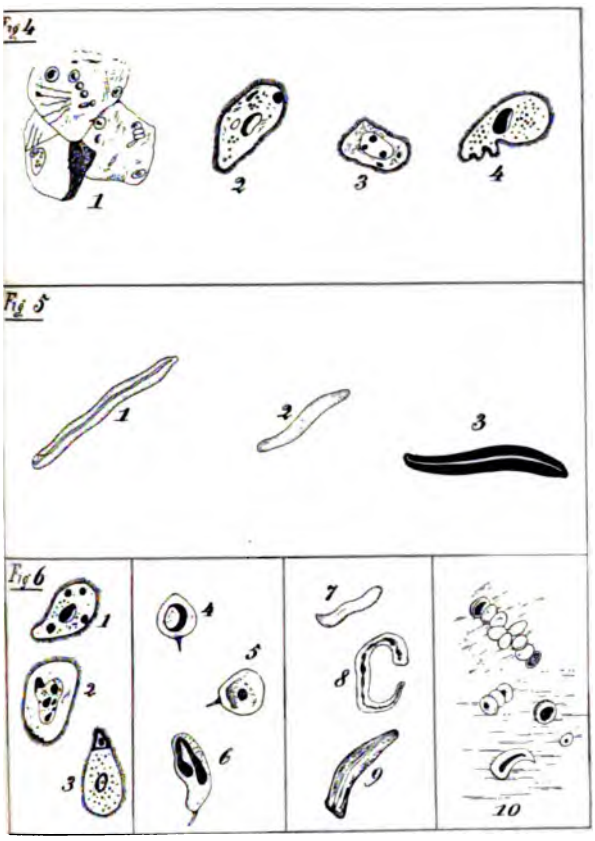

FIG. 4. (Blood from left lung.)
(Fresh specimen.)
(1) Alveoli filled with blood cells and exudate.
(2, 3, and 4) Embryos—without motion.

FIG. 5. (Blood of peripheral circulation.)
(Specimen stained with borax carmine; parasite unstained.)
(1, 2, and 3) Distomæ—7 to 15 micro-mm. long.

FIG. 6. (Blood from the bowel.)
(Fresh specimen.)
(1, 2, and 3) Embryos—showed amœboid movements.
(4, 5, and 6) Ova—amœboid movement and locomotion.
(7, 8, and 9) Parasites—were without motion.
(10) Red blood cells partially disintegrated.

High enemata of a solution of tannic acid seemed to benefit the patient most at this time. On November 1, 1900, we began the hypodermatic administration of phenol. We gave one minim twice a day to begin with, increasing half a minim daily up to three minims twice a day.

At this time our patient was complaining of intense pain caused by the passage of blood clots from left kidney through its ureter into the bladder. Numerous examinations of the infected fluids made during the hypodermatic administration of phenol showed no change in the form, number, or life duration of the organism.

On February 14, 1901, Mrs. R. had her first severe attack of hæmatemesis. Vomitus consisted of blood, food particles, mucus, and epithelial cells; and contained the parasites in forms previously described.

Mrs. R. left our care in September, 1901, and judging from reports which have reached us indirectly at different times, she has at least held her own, and is probably better in some respects.

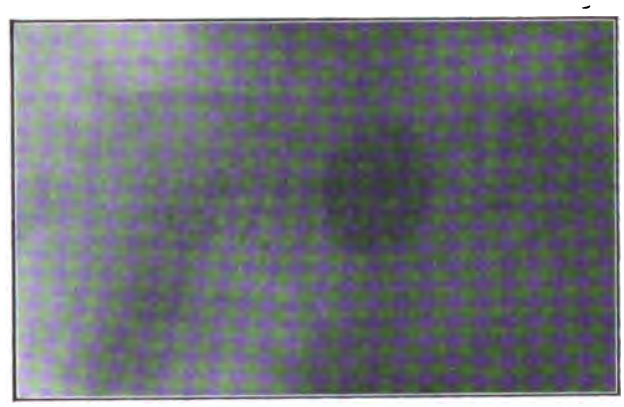
The peculiarities of the case may be summed up as follows, viz., (1) the occurrence of a case at all in this country, when there has been no residence abroad; (2) the almost universal distribution of the organism throughout the patient's body, it being accurately demonstrated in blood from the left lung, from the stomach, from the lower bowel, probably from the pelvis of the left kidney, from the peripheral circulation (finger), and in the urine and fluid from a cyst in communication with the urinary bladder; (3) the excessive hemorrhages over a long period of time (more than a year) and (4) the wonderful resistance of the patient—a woman weighing but 90 pounds, who had undergone two successful abdominal operations, and had been a semi-invalid for ten years.

X-RAY DIAGNOSIS OF AN INTERESTING CASE.

By L. D. WEISS, M.D.,
NEW YORK.

A WOMAN, Mrs. S., brought her child, ten weeks old, for treatment for a cold which the baby had for about ten days. Examination of the child revealed nothing in the chest, although it plainly showed distress in breathing; the mother also said that for ten days the baby had continually held its head in a marked degree of extension; if the head became flexed dyspnœa ensued. The child rarely nursed and was much emaciated. The mother said that about ten days before another one of her children told her that she had put a copper cent into the infant's mouth and that the baby had swallowed it.

Thinking that there might perhaps be some truth in the child's story and also that it might offer some explanation for the extension of the baby's head,



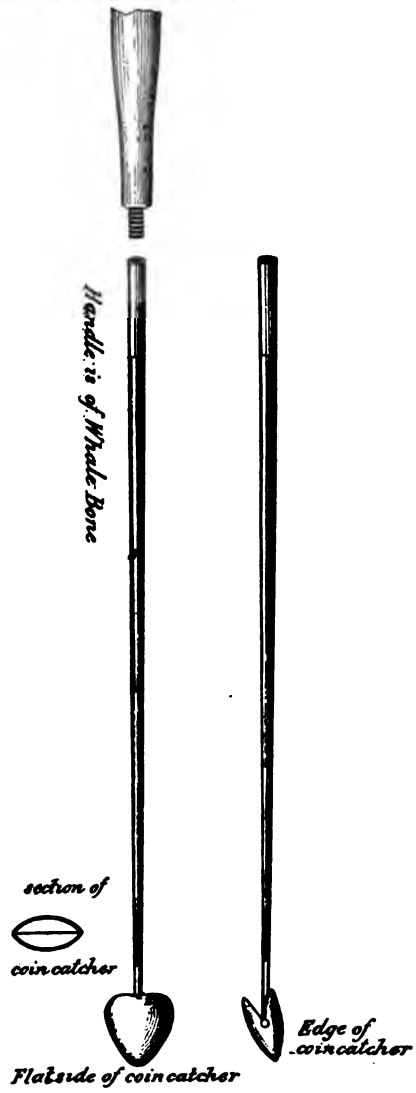
its dyspnœa, and its refusal to eat, I used the *x*-ray and found by fluoroscopic examination that the swallowed coin was imbedded in the œsophagus about on a level with the three upper ribs, as is shown in the accompanying illustration.

The question now arose as to how this coin could be removed; we had two alternatives: (1) grasping it through the mouth by forceps or other instrument; (2) by an incision into the œsophagus. The first was the more logical and tempting one.

The infant was given a few whiffs of chloroform and placed before the *x*-ray, so that, with the aid of the fluoroscope, the forceps (which was in the hands of Dr. W. E. Spicer) could be directed to the coin. The instrument would slip by, back or in front of the coin or fail to grasp it firmly, so we had to aban-

don it and use an instrument known as the coin-catcher.

This instrument resembles a hollow heart with the base cut off and a V section cut out of its thin edges. The receptacle is of silver (so it can easily be seen with the fluoroscope); the handle is of whalebone; the catcher is smooth, so it easily slips past the coin



which becomes engaged in it, and when once engaged the more one pulls the firmer is the grasp on the coin.

When the fluoroscope showed the coin engaged by the coin-catcher, a pull on the handle at once dislodged the cent, and in a few seconds it was drawn through the œsophagus and out of the mouth.

157 West One Hundred and Eleventh Street.

Elasticity of the Skin.—From experiments on frogs, E. Lodholz deduces the following conclusions: (1) The curve of elasticity of skin resembles that produced by a muscle. (2) Supplemental extensibility is greater than that found in muscle, arteries, or elastic tissue. (3) Supplemental extensibility is greater as the number of weights applied to the skin preparation are increased. (4) This phenomenon continues increasing for an indefinite period—in fact, so long as the weight is applied, if the preparation is kept in good condition. (5) Supplemental elasticity is less marked than that found in muscle, arteries, or yellow elastic tissue. (6) The intermittent action of an equal weight produces a curve which usually describes a hyperbole. (7) Supplemental extensibility is inconstant and prevents the production of a constant mathematical curve when heavier weights are added. (8) The higher the temperature the greater the extensibility and the less perfect is elasticity. (9) Alkalies increase and acids decrease elasticity.—*University of Pennsylvania Medical Bulletin.*

Some Points in the Prognosis of Typhoid Fever.—R. E. Sedgwick concludes his paper as follows: The younger the patient, the more favorable the prognosis, as mild cases are commonest in the young, while fatal complications are apt to occur in the old. If the onset of the disease be gradual, it is likely to prove a mild case; but if the onset be sudden, then a severe case must be looked for. If the case be one occurring in an outbreak of typhoid fever, then the general character of the outbreak may be of value in prognosis, the age and constitution of the patient being taken into account. The amount of pyrexia *per se* is not to be regarded as unfavorable in a patient of strong bodily health. The pulse rate is a good indication of the severity of the attack. Sudden changes in its rate are important guides to the onset of complications. Constipation is a favorable symptom contrasted with diarrhœa, which is unfavorable. Meteorism is an unfavorable symptom, because it favors perforation. Where perforation occurs, operative measures hold out the best chance. The dryness of the tongue is a valuable guide to prognosis. Hemorrhage occurs chiefly in serious cases. The earlier it occurs in the disease, the more serious it is. Early nervous symptoms must be regarded seriously, for they are an indication either of the severity of the attack or the lack of resistance in the patient. Most of the complications tend to recovery, serious complications being perforation, peritonitis, and pneumonia. When perforation occurs, laparotomy is the only treatment. Hospital-treated patients have a better chance of recovery than home-treated patients.—*The Birmingham Medical Review.*

The Value of a Fecal Fistula in the Treatment of Typhoid Perforation.—Willard Bartlett says that we are accustomed to think of typhoid perforation as something uncommon and far away, and it is more than gratifying to note how the results attained are gradually improved, and how the most skeptical have been gradually won over to an appreciation of the value of prompt surgical intervention in these cases. The writer gives a number of interesting statistics. Until 1903 it had been the universal practice to close the perforation carefully by sutures, and large statistics have shown that one-fifth to one-fourth of the patients had been saved in this manner. Then it occurred to Escher that the matter of closing the perforation might have something to do with the mortality. He found by searching the literature that one-half of the cases in which the opening had not been found and so was not closed, had recovered, after the abdomen had been drained and a fecal fistula allowed to form. To test the truth of this deduction, he treated four cases by simply bringing the affected loop of intestine up to the parietes, leaving it open and allowing a fistula to form. Three of these cases recovered, a ratio of 75 per cent., which has hardly been equalled in all the history of the subject, no matter what the form of treatment. The fistula in Escher's cases all closed promptly, one spontaneously, and the other two after secondary suture of the abdominal wall. The explanation of his success is very simple. The operation can be performed very quickly, two stitches being all that are required. The bowel can rapidly empty itself. The closure of a large perforation is always attended by the danger of producing an impermeable constriction. The writer gives the history of a case of perforation which he treated in the manner just described. As to the time of operation, the writer would be inclined not to delay longer than is necessary to prepare the patient and the instruments. He believes in the use of a general anæsthetic when a patient is in fair general condition. He calls attention to the necessity for rapid operation. As to the site of the incision, he says that since we can find the lesion in the small intestine most easily by beginning at the ileocolic junction as a fixed point, he can grasp only the lateral incision as the proper routine method, unless there be distinct localized symptoms elsewhere.—*The Medical Fortnightly.*

New York, June 4, 1904.

THE PROGRESS OF CANCER RESEARCH IN GREAT BRITAIN.

THE progress of certain investigations conducted under the immediate direction of the Executive Committee and Pathological Sub-Committee of the British Cancer Research Fund has recently been reported. The investigations made at the Central laboratory were by Dr. E. F. Bashford and Mr. J. A. Murray. The report just published deals with the zoological distribution, the limitations in the transmissibility, and the comparative histological and cytological characters of malignant new growths. The plan of campaign pursued by the British Cancer Research Fund is to follow different lines of inquiry simultaneously. In this manner a multitude of isolated observations have been coördinated by the willing coöperation of many workers in very diverse fields of activity.

The first chapter of the report treats of the investigation of cancer in domesticated mammals, a matter which has received the attention of many observers in the past. The fact is pointed out that even in recent times statements as to the occurrence of malignant new growths in savage races of mankind, and in domestic and wild animals have been occasionally received with skepticism by members of the medical profession, or have been met with the assertion that the disease had possibly been derived from civilized man.

"Within the past year malignant new growths have accumulated," states the report, "from all the domestic animals, and from other vertebrates in captivity and living in a state of nature." In the case of animals a large proportion of the specimens have been removed from those portions of the body which most readily come under observation. In the case of the cow, however, in which the carcases are subject to meat inspection, a larger proportion of the cases have occurred internally, The relative higher incidence of cancer in old age in animals was also shown by the investigations. During the year, 1,500 tame mice were examined, and among these three cases of adenocarcinoma were found. Through the courtesy of other observers, specimens were examined of all the cases of malignant new growths in tame mice which have been described. These include examples of epithelioma, adenocarcinoma, and lymphosarcoma. The report states that the data which have been obtained on the occurrence of cancer in domesticated mammals do not as yet justify any conclusions as to the relative incidence of cancer in these animals.

Respecting the occurrence of malignant new growths in wild animals living in captivity and in state of nature, the following data are given: Among investigations of workers in this field, Professor Scott, Mr. Gilruth (New Zealand), and Dr. M. Plehn (Munich) have decribed carcinoma in the trout. Dr. L. Pick of Berlin has placed on record cases of squamous-cell carcinoma in the hen and malignant cystoma in cryptobranchus. Among wild animals living in captivity only a small number of malignant new growths so far have been placed on record. Two examples of similar growths in marine fish living in a state of nature have been obtained—in a gurnard and in a codfish. A wild mouse was found to be suffering from a spheroidal-celled carcinoma.

Referring to the nature of the malignant new growths of man and animals, the report says: "The histological characters of the malignant new growths of animals are identical with those found in man in all essential features, although the animals themselves are drawn from the different classes of the vertebrate phylum. Squamous-celled carcinoma, adenocarcinoma, and sarcoma can be recognized as readily in them as in man. It is a matter of moment that the malignant new growths in fishes fall into two categories of sarcoma and carcinoma. The unequivocal nature of the microscopical preparations of adenocarcinoma in fish obviates completely the objection that might be raised were sarcoma (so often with difficulty distinguished from infective granulomata) alone recorded in this class. The result of the examinations of various tumors convince the investigators that carcinoma is widely distributed and identical in character, proving that cancer is primarily based on the few conditions which are common to the forms in which it occurs, and only incidentally a problem of human pathology. Thus the essential factors in the causation of cancer must be sought in the potentialities residing in the cells which constitute the living body. Furthermore, the great diversity of the habitat, food, and conditions of life, generally of the forms in which malignant new growths are found, relegates such external agencies to a subsidiary rôle, if they play any part whatsoever, in determining the incidence of the disease."

The zoological distribution of cancer has an important bearing on many current hypothetical theses as to its etiology in man. In connection with this assertion the report says: "The occurrence of cancer in marine fishes living in a state of nature makes it obvious that the conditions of human life peculiar to our modern civilization have not called cancer into being. It remains to be decided whether they have even led to a higher incidence of the disease. In any case those conditions can at the most have a mediate relation to the occurrence of cancer, and the essential preliminaries which lie between them and the initiation of cancer cycle cannot be regarded as their specific reactions. Even in the case of what is known as paraffine cancer, arsenic cancer, etc., the same seems to hold good." The report also treats of the transmissibility of cancer from one animal to another and the comparative cytological characters of malignant new growths which will be considered in another issue of the MEDICAL RECORD.

THE ITALIAN AND PUBLIC HEALTH.

In the MEDICAL RECORD, April 30, some comments were made in the editorial columns on observations of Dr. J. M. Eager with regard to the types of Italian immigrants seen by him at the ports of Naples and Palermo. Dr. Eager said that there were frequently seen at the inspection of immigrants those who deviated slightly from the normal physique, but not sufficiently so as to warrant rejection. Such individuals, though not necessarily effective delinquents, possess moral qualities that under suitable environments develop into criminality, while their lack of physical stamina means proneness to disease. The writer, therefore, was of the opinion that persons possessing these physical and mental characteristics were not desirable as immigrants, and in this view the MEDICAL RECORD coincided.

The May 7 number of *Charities* is devoted wholly to the consideration of the Italian as an immigrant, and in general combats the view that people of this nation are undesirable immigrants. The case for the Italian is ably argued, and in the discussion, by Dr. Brindisi of Boston and Dr. Stella of New York, of the health problems of the Italians in America, the contention is made that the Italian immigrant, upon arrival in this country, is possessed of health and strength. The major part of Italian immigration is, according to the first-named writer, made up of sturdy mountaineers of the Southern Appenines, inured to the most laborious agricultural work. Consequently Italian laborers in this country show a small percentage of disease and a still smaller one of mortality. In 1902 there were 641 deaths among the Italians in Boston. Of the deceased, 175 were born in Italy, and 466 were born in America of Italian parents. The total figures represent 6 per cent. of the total number of deaths in the city of Boston and 11.43 per thousand of the population. This rate of mortality is lower than that of any other nationality except the Russians. Dr. Brindisi presses the point that the physical condition of the Italian immigrants is good, but that their mode of living after arriving in America is contrary to the laws of health, and gives rise to a considerable amount of sickness and to physical deterioration. A very large proportion of Italians settle in the large cities, and herd together in a most unhygienic manner. The women in particular suffer from this change in their habits. Accustomed to a rural out-of-door life, they are suddenly plunged into one of relative inactivity and seclusion, and suffer in health accordingly. Their weakened and impaired physical condition has an injurious effect on the children. The way in which they live in the cities, too, in crowded tenements insufficiently lighted and ventilated, bears heavily upon the health of the young. In short, the morbidity, like the mortality, is larger among the children of the immigrants than among the immigrants themselves. The writer rightly says: "The problem that confronts the student of the hygienic and sanitary conditions of Italians living in the large cities of the United States is threefold, and involves the consideration of the dwelling-houses, the food, and the race conditions." With regard to dwelling-houses, there are two features that attract Italian immigrants in searching for a dwelling—cheapness of rent, and its situation in a locality inhabited by his countrymen. They will flock together in a fashion inconceivable to Americans, and under conditions most prejudicial to the conservation of good health. As to food, Dr. Brindisi states that the American idea with respect to Italians feeding poorly, because they do not eat a sufficient quantity of meat, is a mistaken one. The Italians in the large cities of this country eat much more meat than they used to consume in the old country and still suffer immensely more from stomach troubles here than they did in Italy. Last but not least in the matter of dietetics, the Italians, as a rule, are essentially a temperate race.

Tuberculosis is extremely rife among Italian immigrants. Dr. Antonio Stella says that the extent of its prevalence is not generally known, but that, as a matter of fact, more Italians die of pulmonary tuberculosis in New York City than members of any other nationality, negroes alone excepted. The causes of this proneness to consumption are not far to seek. The Italian immigrant exhibits no inherent susceptibility to the disease, but is rendered disposed to contract the germs easily by the devitalizing influence of the conditions in which he lives. Sleeping in overcrowded dwellings and working in sweatshops and factories quickly undermines the health of a race used to an out-of-door life, and prepares the soil for the bacillus tuberculosis.

There can be but little doubt that immigration is to a certain extent a menace to the public health. As stated in the MEDICAL RECORD, April 30, Dr. Eager says that many Italians are permitted to come to this coutry who are of a primitive type and who are thus specially liable to disease. Even if this number be very small, the Italians are a source of danger to the public health by their habit of herding together in large cities. In New York City alone the total Italian population is estimated at 382,775, an increase of nearly 130,000 since the year 1900. The rational solution of the problem would seem to be that agricultural colonies should be founded, under the ægis of the Italian Government, in which Italian immigrants might lead a life in conformity with their accustomed habits. It is evident that the class of immigrant now flocking into this country is entirely different from that of some years ago, and of course not nearly so desirable. The majority, perhaps, are poor, ignorant, and illiterate to a degree, and by staying in the cities tend to make worse the conditions of already overcrowded districts. In this way at least, if in no other, the Italian immigrants, as well as the Russian, Polish, and Hungarian immigrants, are a distinct menace to the public health.

THE UTILITY OF THE PHONENDOSCOPE.

DR. SEHRWALD (*Deutsches Archiv für klinische Medizin*, Vol. 79, Nos. 5 and 6) reports the results of tests made for a year with an improved phonendoscope, for the purpose of determining whether the instrument possesses any advantages, especially in military service. The instrument consists of a small metallic stethoscope, with a central bore and having interpolated in its shaft a disk-shaped air-chamber 6 cm. in diameter and 2 cm. thick. From the chamber pass two rubber tubes provided with glass or

ard rubber tips for introduction into the ears. The xtremity of the instrument to be applied to the sur-ace to be auscultated has a diameter of 1 cm. The esults of the observations made are summarized as ollows: The phonendoscope is an exceedingly small inaural stethoscope, with an interpolated air-cham-er that acts as a resonator. The instrument can, herefore, intensify and render audible only a defi-ite note, while it enfeebles or suppresses all other otes simultaneously present. Accordingly, it trans-nits murmurs but imperfectly, and, as a rule, it nodifies their character materially. By means of a liding arrangement the air-chamber of the instru-ent can be partially opened and the resonator thus djusted to a higher note. The defects, however, ersist, as the instrument does not transmit deep otes, and it is limited to a narrow range of sound, ielding feebler notes as the opening is increased and hus losing its property as a resonator. When the indow of the air-chamber is open, the sounds from he outside reverberate loudly within the resonator, hile when the window is closed the sound often is ccompanied by a disturbing buzzing or roaring. f the air-chamber is applied directly to the body, he presence of moisture or of hair may be respon-ible for disturbing sounds, which neutralize the ncreased intensity of the note. By the method of ercutory transsonance, the phonendoscope being pplied over an organ and the skin being stroked with a brush in a centrifugal or a centripetal direc-ion from the point of application, the limits can be listinctly determined where the friction-sound becomes fainter or modified in character. The out-lines thus obtained are mostly oval or circular and depend, apart from the vigor of the friction, in the first place upon the character of the superficies of the skin, its dryness or moistness and the amount of fat present, as the intensity of the friction is pri-marily dependent upon these factors; and in the sec-ond place upon the tension of the skin, as the skin conducts the friction-sound the further the more it is stretched in a given direction; and in the third place upon the possibility of freedom of vibration on the part of the skin. If solid, and especially mas-sive, bodies are pressed against the skin from without or within the friction-figures become smaller as the facility of vibration grows less. A portion of the sound-vibrations pass from the skin to the parts immediately underlying. If these are capable of associated vibration, as, for example, the rigid tho-racic wall, friction-figures develop also in them, varying in size and shape in accordance with the same factors as influence the figures on the skin. On the chest sound-conduction is good in the course of the ribs, but distinctly less good at right angles to them. The friction-figures, which are round on the freely vibrating skin, become oval in this situation, the long axis being parallel with the ribs. The same effect is produced when further viscera are situated beneath such a second stratum of tissue. Soft and massive organs are ill adapted to associated vibra-tion and they therefore yield but small figures. The friction-figure upon the skin is a combination of the friction-figures of all parts situated at this point, but not the picture of a single part arbitrarily selected, for example the heart. The figures for the heart can be demonstrated on the chest after removal of the heart. The heart apparently does not influence the friction-sound as a resonator. The friction cannot yield an adequate picture of the heart upon the skin, since the chest, as a projection-surface, has an irregular curvature, and the distance of the several parts of the heart from this surface varies widely. The friction-figures change their position in many situations with displacement of the point of auscultation. Thus, the figure of the heart can be obtained also on the right side of the chest, that of the spleen below the usual situation of this organ, etc. The results, therefore, are often arbi-trary. While the ordinary stethoscope is less con-veniently manipulated in some examinations and yields feebler notes, these are undiminished in ful-ness and unaltered in character, and they are far more reliable and more useful in diagnosis, so that for practical purposes the simple solid stethoscope cannot be replaced by the more complicated and more delicate phonendoscope, which is more bulky and more difficult to put together.

House Infection of Tuberculosis.

Among the most valuable papers read at the Tuber-culosis Exposition in Baltimore in the beginning of this year was that by Dr. Lawrence F. Flick, Director of the Phipps Institute, Philadelphia, on house infection of tuberculosis. The house is the most important factor in the origin and spread of pulmonary tuberculosis. According to Dr. Flick, "The most striking feature about the communicability of tuberculosis is that it depends almost entirely upon the house." "The house is the granary of the tubercle bacillus out-side of its host. Were it not for the house the tubercle bacillus would soon have to perish from the face of the earth. It could not be preserved. Sun-light, air and water are its natural enemies. The water dissolves it out of its cache, and the sunlight and air destroy it."

The house also prepares the soil for the germ of consumption; the system, through living in unheal-thy surroundings and through insufficient nourish-ment, becomes devitalized and harbors and develops the germ with great readiness. Malnutrition is one of the most predisposing causes of tuberculosis. Next to the house, the workshop is chiefly respon-sible for the spread of consumption. The writer asserts that some people work with the contagious stage of tuberculosis for the greater part of a work-ing lifetime, occasionally being thrown out of em-ployment for a few weeks or months on account of an exacerbation, and again returning with as much vigor as before. Owing to the spitting habits of men and women in workshops, a few consump-tives can contaminate an entire shop. The house is the *fons et origo* of tuberculosis, and is also the most potent means of its dissemination.

Dr. Flick summarizes his views on the matter as follows: (1) Tuberculosis is a disease due to the parasitic growth of a microorganism on the tissues of a human being or animal. Being due to organic life, it is communicable. (2) Tuberculosis is con tagious. The contagion of tuberculosis is different from the contagion of acute contagious diseases, however. It is slow and can be avoided easily in the presence of a consumptive, whilst that of acutely contagious diseases is rapid and cannot be avoided in the presence of those who have such diseases. (3) The contagion of tuberculosis is closely asso-ciated with the house. An enclosure of some kind is necessary to make it effective. (4) The house is the granary of the tubercle bacillus. It is the place in which tuberculous matter is kept vital until the bacillus can find a new host. (5) Out of doors tubercular matter becomes devitalized in a short time through water, light, and air. Enough cannot

accumulate in a vital state to create a contagious environment. (6) Everyone has some resisting power to tuberculosis. Some have more than others. Practically all have sufficient resisting power to withstand occasional exposure to tuberculosis and exposure out of doors. (7) For an implantation of tuberculosis prolonged intimate exposure and an intensely contagious environment is necessary to overcome resisting power. This is had in the home and the workshop. (8) The house prepares soil for the tubercle bacillus.

As as been preached persistently in the MEDICAL RECORD, in order to check the inroads of tuberculosis to any great extent, and perhaps in time to wholly eradicate the disease, it must be attacked at its fountain head. Prevention is the only way to conduct a successful campaign against consumption. The only thorough means of prevention are constructing the homes and workshops so that they are well lighted, efficiently ventilated and sanitary in all respects. So long as the wretched rookeries which disfigure all large modern cities, and which are especially a feature of New York, are permitted to exist, just so long will tuberculosis increase and multiply in our midst. The remedy lies to a greater or less degree in the hands of the city authorities; if to the dwellings of the poor were given the attention which is paid to other and more pecuniarily profitable affairs, rapid progress would soon be made in staying the spread of tuberculosis.

PLANS TO FIGHT MALARIA ALONG THE ROUTE OF PANAMA CANAL.

Views with respect to the unhealthiness of the Panama Canal route differ considerably. Some say that Panama and neighborhood is one of the most pestilential districts in the world, and that to fight successfully the insanitary conditions there, will tax to the utmost the resources and ingenuity of American sanitarians and engineers. On the other hand, there are others who aver that the state of affairs from the standpoint of disease has been greatly exaggerated, and that Panama and vicinity, in spite of its evil reputation, can be rendered healthy without the expenditure of a great deal of money or energy. It is likely that the truth lies between these two extreme statements. The canal route is decidedly unhealthy, but is not the veritable death trap that it is popularly supposed to be. However, there is no doubt that the work of purification will test somewhat severely the abilities of those into whose hands the task is placed.

Col. William C. Gorgas of the Medical Department of the United States Army contributes to the New York *Sun*, May 15, an interview in which he sketches a scheme of the plan of campaign which will be followed in the efforts to minimize, as far as possible, the insalubrious qualities of the Isthmus. Colonel Gorgas says in part: "Including the two cities of Colon and Panama, we have at the present time a population of about 40,000 people along the canal strip. The great majority of these people have malaria, and should a large force of foreign laborers be sent to the Isthmus at this time, they would eventually be infected, just as were the French. To correct these conditions we will probably have a year alloted to us before any large force of laborers is thrown into the Isthmus." The speaker has no fear of yellow fever. The same principles will be applied to the Isthmus of Panama that were so successful in extirpating the disease in Havana. Quinine will be used universally among the infected population, and to attain this result a system of hospitals will be established capable of accommodating in the neighborhood of 7,000 patients. All mosquito-breeding places will have to be destroyed, necessitating the employment of a competent inspecting force. Two hundred doctors will be needed along the line of the canal to care for the sick. The sanitation problem, such as street cleaning, sewerage, and water works, will be solved in the same way as in American cities, and there should be very little doubt of its success. At present there is no system at all on the Isthmus.

It may be thought that the opinions of Colonel Gorgas respecting the sanitary regeneration of the canal route are too rosy, but he expresses the views of an experienced authority. He was largely responsible for making Havana a comparatively healthy city. No better man could have been chosen for the position of head of the medical force in connection with the canal construction, and provided that he is given a free hand, he may be relied upon to remove the ill name which has so long attached itself to the Isthmus, and to alter the insanitary conditions prevailing there to such an extent, that Europeans, taking proper precautions, may live in as good health as in the majority of tropical countries.

HIGH BUILDINGS AND PHYSICAL DEGENERATION.

That extremely high buildings are not conducive to the good health of the inhabitants of a city has been often asserted. The arguments in support of this contention are plausible and even more or less convincing. The buildings known as skyscrapers, indigenous to America and conspicuous in all its cities, exclude to a great extent light and air from the streets on which they are situated. Human beings need all the light and air possible, and when these are lacking they suffer in health, therefore high buildings are a menace to health. An inquiry is proceeding in Great Britain at the present time with regard to the physical degeneracy of the British race. Dr. Warner has recently examined 100,000 London children, and reports that one sign of degeneracy is that the heads of children are growing smaller, especially those of females. Dr. Warner says that this is due chiefly to the erection of high buildings. He offers no explanation of his theory, but states that where residences are of great height and size a larger proportion of small heads are found. In Kensington, where high buildings are numerous, the state of affairs in this respect is worse than in Whitechapel and Bethnal Green. In fact, it is bad in all districts in which lofty buildings are common. Dr. Warner suggests that in certain localities want of light and air shut out by high buildings may account for small heads.

The craze in the United States for erecting twenty and thirty-story buildings has, in the majority of instances, little in its favor. In New York there is some excuse for the custom owing to the narrow and cramped area of the city proper. In other cities, however, the erection of skyscrapers is to be condemned. They are not beautiful or æsthetic, some of them, indeed, offend all the canons of art and are hideous in the extreme, while they are obviously prejudicial to the public health by reason of the manner in which they exclude light and air. In the crusade against consumption now being waged in America, the subject of high buildings as a cause might be taken up. Plenty of light and air is a necessity in the preservation of good health, and where these are not available physical degeneration will take place.

News of the Week.

The Fifteenth International Medical Congress.—n common with many others we have had grave oubts regarding the wisdom displayed in the selec- ion of Lisbon as the place of meeting of the next nternational Congress, but we have to confess that he first official bulletin, just issued, has weakened hese doubts. There is certainly no sign of pro- rastination—no mañana—in what has thus far been ccomplished. The committee on organization has lready held two meetings and the executive com- ittee four. The officers of the congress have been ppointed, the statutes adopted, the various sections rganized, and the foreign and national committees re being constituted. The organizer of the United tates committee is Dr. John H. Musser of Phila- lelphia, President of the American Medical Associa- ion for 1904. The congress will be held at Lisbon n April 19-26, 1906. The congress will be divided nto seventeen sections, as follows: (1) Anatomy descriptive and comparative anatomy, anthropol- gy, embryology, histology); (2) Physiology; (3) General pathology, bacteriology, and pathological natomy; (4) Therapy and pharmacology; (5) Medi- ine; (6) Pediatrics; (7) Neurology, psychiatry, and riminal anthropology; (8) Dermatology and syphilog- raphy; (9) Surgery; (10) Medicine and surgery of the urinary organs; (11) Ophthalmology; (12) Laryn- gology, rhinology, and stomatology; (13) Obstetrics and gynecology; (14) Hygiene and epidemiology; (15) Military medicine; (16) Legal medicine; (17) Colonial and naval medicine. The official language is French, but in the general and sectional meetings English and German are permissible. Portuguese is excluded, the committee explaining that this has been done to reduce the babel of tongues, others, whose national speech may seem slighted, being estopped from complaining "when the legislator sacrifices himself." The membership fee is 25 francs ($5). The president of the Committee of Organization is Dr. M. da Costa Alemão; the general secretary is Dr. Miguel Bombarda (Hospital de Rilhafolles, Lisbon), to whom all communications should be addressed.

Peace.—Dr. Frederic C. Curtis, Secretary of the Medical Society of the State of New York, writes that an invitation has been extended to the Presi- dent, Dr. H. D. Wey of Elmira, and members of the Medical Society of the State of New York by Dr. John H. Musser, President of the American Medical Association, to attend the meeting of the association at Atlantic City, June 7 to 10, and take to part in the scientific proceedings. Notice of this is given to the members of the society who may desire to attend and avail themselves of the invitation as well as to the members of the country medical societies.

The International Tuberculosis Congress was opened in Copenhagen on May 27, Prof. Brouardel of Paris presiding. Crown Prince Frederick, the Ministers, and Members of the Diplomatic Corps, in- cluding United States Minister Swenson, were among those in attendance. Delegates from twenty countries, among them Dr. Pottenger of Los Angeles, Cal., and E. L. Trudeau of Saranac Lake, N. Y., were present. Premier Deuntzer welcomed the delegates.

The Hospital Graduates' Club.—The nineteenth anniversary of the foundation of this society was celebrated by a dinner at the Hotel Manhattan on the evening of May 26, a large proportion of the members and many invited guests being present. The presi- dent, Dr. Arthur L. Fisk, was toastmaster, and speeches were made by Professor Canfield of Co- lumbia, ex-Dock Commissioner McDougall Hawkes, Mr. H. G. Carlton, Rev. Dr. Hyde, and Drs. D. B. St. John Roosa and John W. Brannan of New York, and Hobart A. Hare of Philadelphia.

American Association of Life Insurance Exam- iners.—The annual meeting of this association will be held at Atlantic City, N. J., on Monday, June 6, the day preceding that of the American Medical Association. The program contains the titles of fifteen papers to be read. There will be a morn- ing and afternoon session on the pier and an evening session at the Hotel Islesworth, which will be the headquarters of the association. Dr. Chas. Lyman Greene of St. Paul is president, Dr. J. J. Morrissey secretary, and Dr. Denslow Lewis chairman of the Executive Committee.

Dr. George M. Lefferts.—At a meeting of the Faculty of Medicine of Columbia University, held May 23, 1904, it was voted that the following minute be entered in the records of the meeting and that a copy thereof be sent to Dr. Lefferts: "Upon the acceptance of the resignation of George Morewood Lefferts, M.D., M.Sc., Clinical Professor of Laryngol- ogy and Rhinology at the College of Physicians and Surgeons, the Medical Department of Columbia Uni- versity in the city of New York, the faculty of the college desires to express its high appreciation of the distinguished services which through three decades he has rendered to the institution. The organiza- tion and maintenance of an important practical clin- ical department in the college, eagerly sought by the students of successive generations, and a model of efficient administration, we recognize as a large achievement in the career of a busy practitioner. This long and faithful service and the generous gift to the college of a valuable collection of illustrative specimens and charts are held in high appreciation by his colleagues. A wise and successful teacher, an eminent practitioner, and a genial associate, the faculty acquiesces in Dr. Lefferts' retirement with reluctance and regret."

A New Dysentery Bacillus?—A despatch to the *Sun* from Colombo says that Professor Castellani, who occupies the chair of pathology and bacteriology at the Colombo Medical College, announces that he has discovered the bacillus of dysentery. He is experimenting with preventive serums and a cura- tive vaccine.

Prof. Wilhelm His died at Leipsic on May 1 after a long and painful illness. He was born in Basle July 9, 1831, and had therefore nearly com- pleted his seventy-third year at the time of his death. He studied medicine in Basle, Berne, Berlin, Würzburg, Prague, Vienna, and Paris. In 1857 he was appointed professor of anatomy at Basle, suc- ceeding Meissner, who had received a call to Göttin- gen. In 1872 he was called to Leipsic to take the newly established chair of anatomy. Carl Ludwig taking hat of physiology, and both succeeding Weber, who had held the united professorship in these two subjects. The scientific contributions of His exceed one hundred and embrace a great variety of subjects, including the anatomy of the cornua, the structure of adenoid tissue, and the lymphatic sys- tem. But it was as an embryologist that His won his greatest renown, his *magnum opus* being "Über den Bau des Säugethiereierstocks." In an appreci- ation of His in *The Lancet* of May 21, 1904, to which we are indebted for the facts above stated, Dr. Wil- liam Stirling of Manchester says that "when we survey the immense amount of original work which His accomplished we can well say that 'prodigious' was his energy and his application and untiring was his zeal. When we remember that all th s was accomplished along with the active performance of the duties of a professor of anatomy in a great school

of medicine, we can only wonder how it was done. His was a clear and explicit lecturer, a draughtsman of the highest ability, and marvelously beautiful were the pictures which he built up before his audience in the lecture theater. All the drawings—and they were legion—for his various papers and monographs were drawn by his own hand either directly or by means of his embryograph. Many are the anatomists who studied under him. In our own country we may mention Symington and Gemmill and across the pond Hall, Clark, Flint, and MacCallum. Endowed with a charming personality and a manner at once suave and inviting, His attracted round him groups of young investigators eager to work under him. He was always ready to help the beginner and to guide him by his wise counsels."

Reception Hospital for the Insane.—About two weeks ago Governor Odell announced his approval of Senator Foley's bill authorizing the city of New York to acquire a site and to lease it to the State for the establishment thereon of a reception hospital for the insane, and authorizing the State Commission in Lunacy to erect such a hospital.

Annex for St. Vincent's Hospital.—Plans have been filed with the Bureau of Buildings for the new six-story fire-proof annex for St. Vincent Hospital, to be erected at the northeast corner of Seventh avenue and Eleventh street, and to be known as the West Wing. It is to adjoin the new main building on Eleventh street and will have a frontage of 90.4 feet and a depth of 94½ feet with a façade of brick and stone harmonizing with the main edifice. There will be a solarium on the sixth floor and quarters for the Sisters on the fifth floor.

The Lenox Medical and Surgical Society.—In place of the annual meeting of this society, on the evening of May 28, a dinner was given by the members at the New York Athletic Club in honor of their fellow member, Dr. William Kelly Simpson. Dr. Charles W. Allen presided, and all of those present, members and guests, to the number of about thirty, made brief addresses of congratulation to the guest of honor on his appointment to the chair of laryngology at Columbia University.

Missouri State Medical Association.—The following officers were elected at the annual meeting of the Missouri State Medical Association held at St. Louis May 17 to 20 inclusive: *President*, Dr. Jabez N. Jackson of Kansas City; *Vice-President*, Dr. S. M. Brown of Monroe City; *Secretary*, Dr. C. M. Nicholson of St. Louis; *Assistant Secretary*, Dr. E. J. Goodwin of St. Louis; *Treasurer*, Dr. J. Franklin Welch of Salisbury. The next annual meeting will be held at Excelsior Springs.

Typhoid Fever Declining in Philadelphia—For the week ended May 28 there were reported to the Philadelphia Bureau of Health 120 cases of typhoid fever, as compared with 182 for the week ended May 21, and 295 for the week ended May 14. The number of deaths from the same cause was, for the respective weeks, 22, 30, and 25. The total number of deaths during the three weeks indicated were 494, 477 and 520 respectively.

Dr. John E. Greiwe has been appointed adjunct professor of the practice of medicine at the Medical College of Ohio.

Medical College of Ohio.—On May 25 this institution, which comprises the Medical Department of the University of Cincinnati, held its eighty-fifth annual commencement. Addresses were made by the dean, Prof. P. S. Conner, the acting president of the University; Prof. Joseph Edward Harry, and Prof. Allyn C. Poole. The class consisted of forty-six graduates, and members secured nineteen out of twenty-two hospital appointments in Cincinnati as well as several in other cities.

Covington (Ky.) Board of Health.—Dr. Orrin Lyle Reynolds, Dr. E. S. Stuard, and Dr. M. Behrman have been elected by the City Council as members of the Covington Board of Health to fill vacancies left by Dr. W. W. Ranshaw, George O'Maley, and Dr. C. T. Mooffet.

Reciprocity Convention.—The third annual convention of the American Confederation of Reciprocating, Examining, and Licensing Medical Boards was held in Chicago May 24. The Examining or Licensing Boards of the States of Illinois, Indiana, Wisconsin, Michigan, Iowa, Nebraska, Kentucky, and Maryland were represented. The address of the President, Dr. W. A. Spurgeon of Muncie, Ind., dwelt on the insufficiency of the courses in the colleges and the lack of proper relation between the various branches. He advocated regulation of the medical college curricula and of State Board questions as a basis for reciprocity and uniformity.

Medical College of Ohio Alumni held their annual banquet on May 25 at the Alms Hotel, Walnut Hill. One hundred and fifty members were present. Dr. J. H. Landis of 1890 acted as toastmaster, and toasts were responded to by Dr. Oscar Berghausen of the graduating class; Dr. A. H. Freiberg, 1890; Dr. David P. Gillian, 1871; Dr. E. G. Reynard, 1884, and Dr. P. S. Conner.

Baby Incubator at the World's Fair.—This building is located on the Pike and was opened to the public on May 27. The building is a spacious one, well lighted and ventilated, and contains fourteen incubators. They are square with metal frames and glass sides. The air which the baby breathes is carefully screened and purified before it reaches the little occupant of the glass box. A temperature of 90° F. is maintained without variation of more than half a degree. At present there are ten babies under the care of the physicians. Among these are two little babies, twins, whose combined weight is but seven and one-half pounds. Dr. Joseph B. Hardy is in charge of the exhibit, and a staff of consulting physicians will be appointed next week.

Identity of Human and Bovine Tuberculosis.—The British Royal Commission, appointed in 1901 to investigate the theory adopted by Koch that human and bovine tuberculosis are not intercommunicable, has made a preliminary report in which this view is condemned. The commissioners say that they "have most carefully compared the tuberculosis set up in bovine animals by material of human orig n with that set up in bovine animals by material of bovine origin, and so far have found the one, both in its broad general features and in its finer histological details, identical with the other," and they conclude that "it would be very unwise to frame or modify legislative measures in accordance with the view that human and bovine tubercle bacilli are specifically different and that the disease caused by one is wholly different from the disease caused by the other."

New Hospital Building Dedicated at Dayton, Ohio.—The new operating building at the Miami Valley Hospital, given by Mrs. Frank J. Patterson in memory of her husband, was dedicated May 26. Mrs. Patterson made a short address, which was responded to by Dr. H. F. Colby.

University of Illinois Commencement Exercises.—A class of 219 was graduated from the college of Physicians and Surgeons, the Medical Department of the University of Illinois, May 24. Prof. Thomas J. Burrill, Vice-President of the University, con-

ferred the degrees, and Rev. A. R. Lambert delivered the doctorate address.

Dr. J. T. Halsey of Montreal, Assistant Professor of Pharmacology and Therapeutics of McGill University, has been elected to the corresponding professorship in the medical department of Tulane University, New Orleans. He is a graduate of the College of Physicians and Surgeons of New York and has been devoting himself entirely to laboratory and didactic work.

Railway Surgeons Elect Officers.—The C. H. & D. Railroad surgeons, at their meeting at Dayton, Ohio, elected officers as follows: *President*, Dr. M. F. Hussey, Sidney; *Vice-President*, Dr. C. E. Beardsley, Ottawa; *Secretary*, Dr. Mark Millikin; Hamilton; *Treasurer*, Dr. W. E. Phesing, Cincinnati.

Obituary Notes.—Dr. EDWIN GAILLARD MASON of New York died at the home of his father, Dr. A. S. Mason, in Hagerstown, Md., on May 24. He was thirty-nine years old, and was a graduate of the Bellevue Hospital Medical College in the class of 1887. He was assistant professor of nervous diseases at the New York Polyclinic for several years. He was editor of *Gaillard's Medical Journal* for eight years. He was also a vice-president of the Southern Society of New York, and was a member of the Medical Society of the County of New York and of the Alumni Association of St. Mary's Hospital. His wife and two children survive.

Dr. RALPH M. ISHAM of Chicago died at Lake Forest, Ill., on May 28, of cancer of the stomach. He was a graduate of the New York University Medical School in the class of 1854. He served as a member of the Sanitary Commission during the Civil War, and later had charge for a time of the U. S. Marine Hospital at Chicago.

Dr. ARTHUR MAXWELL LINE died suddenly at Wilmington, Del., on May 29, at the age of thirty-three years. He was a graduate of Harvard and the College of Physicians and Surgeons, New York. He served as a private in Troop A of New York in the Spanish War, and later was post surgeon at Fort Riley, Kan.

Dr. THOMAS MURRAY DRYSDALE died in Philadelphia from pneumonia on May 26 at the age of seventy-two years. He was graduated from the Philadelphia Medical College in 1852, and in 1855 became professor of chemistry in the Wagner Free Institute of Science. In 1863 he was appointed surgeon in the First Pennsylvania Infantry, serving in this capacity until the close of the Civil War. Later he confined himself largely to the practice of gynecology, attaining a distinguished position in this field of medicine. He was at one time president of the Philadelphia Country Medical Society and at another time president of the Philadelphia Obstetrical Society. He was also a vice-president of the American Academy of Medicine. His widow was a daughter of the late Dr. Washington Atlee.

Dr. FRANK SAVARY PEARCE of Philadelphia died at his father's home in Steubenville, Ohio, on May 27, after a brief illness, at the age of thirty-six years. He was graduated from the medical department of the University of Pennsylvania in the class of 1891, and was subsequently a resident physician in the Presbyterian and Orthopedic Hospitals of Philadelphia. Later he was elected Professor of Neurology in the Medico-Chirurgical College, neurologist to Howard Hospital, and neurologist to the Philadelphia Hospital. He was a frequent contributor to medical literature, and he was the author of a text-book on nervous diseases but recently published, and he was at work on a companion book on mental diseases.

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent.)

ABDOMINAL SURGERY—DANGER OF LEAVING SPONGES, ETC., IN THE CAVITY—MEDICAL SOCIETY—MEDICAL AND CHIRURGICAL MEETING—SIR H. THOMPSON'S WILL—THE LATE AUSTIN MELDON.

LONDON, May 14, 1904.

THE medical talk of the week has been chiefly concerning a lamentable occurrence at the West London Hospital. A women was admitted with internal hemorrhage from a ruptured Fallopian tube and the abdomen had to be opened to give her a chance of life. It was done successfully in spite of the profound collapse and she rallied. But rigors of peritonitis set in and later a second operation was performed, when it was found that a small pair of forceps had been left in the cavity at the first operation. The patient succumbed and at the inquest the jury returned a verdict of "Death from misadventure due to peritonitis following an operation accelerated by the presence of the forceps." To this they added a recommendation that all instruments should be counted before and after operations. Of course, this is the general practice. In this it appears that the most obvious precaution was unaccountably omitted, as although the sponges used were carefully counted, the instruments were not. This seems to give rise to some difference of opinion, or rather I should say that explanations have been put forward, but I fear the public will not regard them as satisfactory One of these seems to be that the present practice is very rarely to put on forceps out of sight. But even so the precaution of counting may well be taken lest a pair should slip out of sight, which is likely to happen in these operations. Nor is it instruments only that are concerned. Sponges, swabs, gauze, and so on, may be easily overlooked. In fact, this has happened in many other cases. Spencer Wells himself recorded how this accident occurred to him twice. He was, of course, in a position to tell the circumstances and doing so is to his credit. But if so careful and experienced an operator thus suffered it is not surprising that now and then the same sad occurrence is reported

I believe at least 200 such instances have been published, and probably others have taken place but have not been recorded.

There are those among us who believe that no method can insure absolute immunity from occasional mishap, and this may be the case so far as the method involves the necessity of human attention.

The operator cannot always be in a condition at the close of an emergency operation demanding his utmost mental efforts to supervise the count or still less to count himself, and it seems obvious that the care of all the things used and their number should be intrusted to one person who should be responsible for that duty and that alone, just as the anæsthetist is expected to devote all his attention to his own work and take no notice of anything else. As the danger of overlooking something used has long been an ever-present one to the surgeon, various methods of diminishing it have been employed. I do not propose to discuss them here, but may remark that Spencer Wells at one time used the simple plan of letting a long piece of silk hang from each instrument and sponge outside the abdomen. This is no doubt at times inconvenient but I believe has usually been successful.

Ireland has just lost one of her foremost surgeons, Mr Austin Meldon, who died very suddenly on April 28, while in the act of dictating a letter to his wife. The deceased gentleman, who had a most distinguished collegiate career, occupied pretty well every position of importance open to a member of his profession in his native city. He was an ex-president of the Royal College of Surgeons, Ireland, and three times president of the Irish Medical Asscciation. Soon after becoming a Licentiate of his college, Mr. Meldon was appointed surgeon to the Jervis Street Hospital, a position which he relinquished about a year ago, when he was elected to the consulting staff of the same institution, where much of his life-work was done. Always busy, in a professional sense, the deceased surgeon yet found time to write valuable contributions to medical literature on a variety of subjects, for instance on "Operative and Conservative Surgery," which he contributed to the *Dublin Quarterly Journal of Medical Science*; "Gunshot wounds"; the "Treatment of Tetanus" (read before the British Medical Association in 1887), etc.

At the time of Mr. Meldon's lamented death he was on the commission of the peace for Dublin, and was generally beloved and respected by his fellow-townsmen, both lay and professional, an immense concourse of whom followed him to his resting place in Glasnevin Cemetery,

where he was laid on Monday, May 2, in the sixtieth year of his age and the thirty-ninth of his distinguished professional career.

Notwithstanding his unusual size (28 stone), the late Mr. Meldon was a very active man, and an expert player of cricket and lawn-tennis, he was also well known as a cyclist, and, speaking generally, was passionately attached to, and excelled in, all athletic sports.

The late Sir Henry Thompson has left an estate valued at £226,000. He has also left a manuscript work which is sure to be of interest to the public as it is a record of his "Personal Recollections." But the public must wait, for he has directed his trustees to retain it for ten years and not to divulge the contents or any part thereof during that period, and then to cause it to be printed and published, taking steps to secure the copyright.

OUR VIENNA LETTER.

(From Our Special Correspondent.)

ANTISTREPTOCOCCUS SERUM IN PUERPERAL SEPSIS—NASAL TUBERCULOSIS—TREATMENT OF LUPUS—EPIDEMIC OF MEASLES—ATTENDANCE AT THE UNIVERSITY—OPENING OF THE PHYSIOLOGICAL INSTITUTE—DEATH OF ADOLF SCHERMANN.

VIENNA, May 4, 1904.

It was at Vienna that the genial Semmelweiss aroused a storm of protest and antagonism by his announcement of the discovery of the etiology of puerperal fever. It was not until after the death which released this unfortunate observer from the insanity with which he became afflicted that the truth of his claims was established, and the immediate result was the rapid decline in the number of cases of this disease in the hospitals. But even with the most careful asepsis and antisepsis, the number of cases occurring in Austria is still very large. In 1899, 1,661 cases of puerperal fever were reported in the Empire, of which 937 ended fatally. In Germany, France, and England the conditions are not much better.

And now another discovery apparently emanates from this same Vienna, with which it is hoped to combat successfully this dread scourge of young mothers. A short time ago, at the meeting of the Association of Physicians, Dr. Poham presented the results of his experiments carried out in Chrobak's clinic, with the antistreptococcus serum produced by Professor Paltauf. As compared with Marmorek's, this serum has been found to be particularly efficient, and the results thus far obtained point to a very hopeful outlook. Twenty-six patients in Chrobak's clinic with severe puerperal infection were put under treatment, and it was possible to save a considerable number which would have been regarded as hopeless when previous therapeutic measures were in vogue. The serum, however, is only effective in those cases in which the infection has been caused by streptococci. It is a specific streptococcus antitoxin and has no influence where the infection is due to other pyogenic bacteria. The serum is secured from horses which have been inoculated with streptococci derived from women affected with puerperal sepsis. The patients receive from 100 to 250 c.cm. by injection—at least this quantity being required to secure any results. An interesting thing is the fact that the serum from different horses varies greatly in its efficiency.

A case of localized nasal tuberculosis, which is an exceedingly rare condition, was presented by Dr. Fein at the same meeting. The patient was a nurse twenty-five years of age. At the anterior end of the right lower turbinate there was present a tuberculous infiltration, without any involvement of the septum or the external skin. Aside from an enlargement of the submaxillary and cervical lymph nodes, there were no evidences of tuberculous foci elsewhere. The histological examination showed numerous tubercles, with isolated giant cells, but as there were no evidences of cheesy degeneration, the clinical picture was rather that of lupus. The differentiation of lupus and tuberculosis of the mucosa, however, is a very difficult matter.

Nasal tuberculosis is a very rare condition, especially the localized variety, and finding the same on one of the turbinates without any involvement of the septum may be considered without precedent. The patient's calling warrants the assumption that a primary infection in this case is not unthinkable. The woman had no suspicion of the true nature of her disease, and had submitted to an examination in order to ascertain the cause of the enlarged lymph nodes. The consequent discovery of the lesion and the fact that an auricle accommodates the disease, should lead one to make a careful examination of the upper air passages in cases in which a chronic enlargement of the lymph nodes of the neck is present, for which no other cause is apparent. Caries of the teeth, also, must not alone be considered as a sufficient cause for the adenitis, although in this instance this was also found.

Professor Ehrmann presented two cases of lupus which had been treated by a combination of two methods. The one patient was a girl of eighteen, with lupus of both cheeks; the other a man of forty, with a lupus tumidus of the nose. The former has been treated since the 22d of January, the latter since the 2d of February. Resorcin paste (33 per cent.) was first applied until the upper layers were removed, then the *x*-rays were directed on the deeper parts of the growth. As the rays do not penetrate very far into the tissues, the method accomplished a considerable reduction in the time required for treatment. In the girl every trace of the lupus had disappeared after the third radiation, and in the man seven exposures had eradicated all the disease with the exception of a very small nodule.

Vienna is just at present being visited by a very extended epidemic of measles, although the individual cases are all of a very mild character. A short time before the beginning of the epidemic the head physician of the Children's Hospital (Franz Joseph) announced that he had observed a hitherto undescribed infectious disease in four children. Two of these cases had been admitted with the diagnosis of scarlet; the other two were believed to have measles. The disease is marked by a peculiar eruption, which, even on close inspection, can with difficulty be distinguished from the ordiary eruption of measles. Fever is regularly present, but disappears after a few days. The disease is a mild one. One thinks at first of measles, but the further course of the affection shows that an error has been made. The rash disappears very often in a few hours. It exhibits a remarkable localization. Beginning on the trunk in the form of dark red spots, as large as a pea or a bean, it spreads over the face and rather sparsely over the extremities. In some cases severe vomiting was present at the beginning of the attack, and also total loss of appetite. Complete recovery resulted in two or three days without complications. The only after-effect observed was the rather obstinate loss of appetite, which did not disappear for several weeks. It is not unlikely that the rapid increase in the number of measles cases reported in Vienna may be attributed to the presence of this hitherto unknown disease.

The summer session of the university has begun, but the attendance is not so large as usual. The coming generation is evidently not attracted to the medical profession, with its difficult courses of study, for which the present unfavorable social conditions seem to offer little encouragement for the future. The number of medical students in Austria is consequently steadily decreasing, and the professors are first to observe this in their lectures. The clinics have undergone few changes. Professor Hohenegg has taken the clinic of the deceased Gussenbauer, and Professor Finger has been announced as the successor of Neumann, who has given up teaching on account of his advanced years.

On the 2d of May medical circles of Vienna were treated to a mild sensation. In the presence of the Minister of Education, the new physiological institute of the university was opened with appropriate ceremonies. The large auditorium is placed in front of the main building and is semicircular in form. Entrance and exit is gained without going through the institute itself. The unique plan of this auditorium is the idea of the director of the institute, Prof. Sigmund Exner, and may be alluded to as a physiological auditorium and not merely an auditorium for physiology. The sloping ceiling gives it the form of an immense sounding board. The lecturer's platform is at the lowermost point, from which the rows of seats rise in the manner of an amphitheater. Suspended above these seats is a gallery, also provided with seats. The latter will no doubt be in demand, as from them a direct view can be obtained of the pit and the tables for the demonstrations. Abundant side light is provided. The room has been much admired by all foreign physiologists and architects, and it may be of interest to American colleagues to know that the architect, Charles A. Marsh, is planning an auditorium of the same type in Chicago. The institute is a model in every respect, and one is regretfully reminded of the founder of the Austrian School of Physiology, Ernst Brücke, who labored here for forty years in miserable quarters, and yet submitted to the world a series of the most important discoveries.

In Budapest there died a few days ago Dr. Adolf Schermann to whose laborious efforts are due the improved sanitary conditions and the decrease in the death rate of the Hungarian capital. Only a short time ago he made a most original suggestion to the municipal authorities which is deserving of mention. Schermann considered it essential that the cardinal rules of hygiene should be thoroughly impregnated in the mind of the people, and suggested a unique method for attaining this end.

all these primary regulations can be versified in such a form that they will readily become impressed on the ear and mind, and may then be taught to the school children. The suggestion will soon be adopted in Hungary, and will no doubt meet with success.

OUR PARIS LETTER.

(From Our Special Correspondent.)

DR. NETTER AN ACADEMICIAN—MINERS' ANÆMIA—INTERMITTENT HYDRONEPHROSIS—HOSPITAL GRADUATES' SOCIETY OF PARIS—THE FRENCH CONGRESS OF OBSTETRICS, GYNECOLOGY, AND PEDIATRICS—THERAPEUTICS OF HORSE SERUM—DEATH OF PROFESSOR DUCLEAUX.

PARIS, May 8, 1904.

At the Académie de Médecine, Dr. Netter has been elected titular member in the section of Public Hygiene, to fill the place of Professor Proust, deceased.

The Académie is at present interested in the question of miners' anæmia, which is due principally to ankylostomiasis. Manouvriez has shown the mechanism of anæmia due to ankylostomiasis. This anæmia is produced sometimes by repeated hemorrhages from the intestinal mucosa due to ankylostoma; it is sometimes due to the phenomena of intoxication. On account of the ravages made by ankylostoma in the mines of France and Belgium, a committee proposed by Professor Blanchard, was nominated by the Académie to study the question.

The Société de Chirurgie of Paris has been listening to an interesting discussion on the pathogenesis and diagnosis of intermittent hydronephrosis. Concerning the pathogeny, Bazy thinks that hydronephrosis is due principally to a particular formation of the pelvis characterized by a congenitally abnormal anastomosis of this reservoir with the ureter. On account of an abnormal bend of the ureter at its origin, there results a retention of urine in the pelvis, which dilates mechanically, and under the influence of the increase of weight and volume of the kidney, there result ptosis and abnormal mobility of the organ. The overlapping, the bend of the ureter over the renal artery, that is generally considered as the cause of hydronephrosis, is in reality only secondary; for the renal artery is relatively fixed, and it is the lower part of the renal pelvis which in its distension, sinks further and further below it, till the ureter forms a cross which embraces the artery. This phenomenon, which is very frequently observed, is only the consequence and not the cause of hydronephrosis.

In connection with the diagnosis of intermittent hydronephrosis, much was said at the meeting of the Société de Chirurgie of April 27, 1904, concerning the great superiority of the Luy's separator for the intravesical separation of urine, over ureteral catheterism. The separator shows exactly the condition of the function of ureter and kidney, by proving that when there is a bend in the ureter, not a drop of urine is received into the corresponding tube. But it is sufficient, while the separator rests in place in the bladder, to raise up the diseased kidney toward the diaphragm, simply by means of placing the two hands in the flank, in order to cause the urine to flow into the empty tube.

Ureteral catheterism, on the contrary, which always forcibly straightened out the ureteral curve, and thus gives an exit to the urine retained in the pelvis is misleading as to the function of the ureter, since it tends to make one believe that there is a natural permeability of the canal when there is only an artificial permeability created by the sound.

The first scientific reunion of the internes and ex-internes of the hospitals of Paris, took place on April 28. Doctor Fernand Widal gave a remarkable address on a subject in which he is much interested—"Déchloruration," its indications and therapeutic results. Dr. Widal clearly showed the important rôle that the complete exclusion of salt from food plays in the course, for example, of nephritis. It has also been proved by many observations, how superior to the strict milk regime are the results furnished by food consisting of meat and the other ordinary articles of diet, but completely deprived of salt as a seasoning.

Finally at Rouen, from April 5 to 10, 1904, there was held the fourth session of the "Congrès National d'Obstétrique, de Gynécologie, et de Pédiatrie," with Dr. Richelot as president.

In the section of Pediatrics, Barlow's Disease was discussed, Drs. Ausset (of Lille), Oui, Guinon, and Deroque taking part. The subject of the "Gouttes de Lait" also came up for discussion. Finally, Dr. Grisel presented a report on Intestinal Invagination in Children.

In the section of Orthopedics, Drs. Broca and Deroque reported the remote results of the tendinous transplantation in infantile paralysis, and Dr. Gourdon (of Bordeaux) gave the results of his studies of the bloodless treatment of congenital dislocation of the hip.

In the section of Gynecology and Obstetrics, the question of the day was Pyelonephritis in its relations to pregnancy. This subject was discussed by Drs. Leguen (of Paris), Audebert (of Toulouse), Martin (of Rouen), Potocki, Bender, Wallich, and Pinard (of Paris). Their conclusions were as follows: In bilateral pyelonephritis, when the disorder was severe enough to necessitate intervention, the induction of premature labor was justifiable. In unilateral pyelonephritis, on the contrary, nephrotomy was justifiable in the seventh or eighth month of pregnancy, and it was only in the last period that this affection justified the induction of premature labor.

Dr. Oui (of Lille) presented a report on hysteropexy looked at from the viewpoint of its influence on future pregnancies.

Dr. Raymond Petit (of Paris) discussed the property of horse's serum to cause a local accumulation of polynuclears which play the part of phagocytes to the microbes of infection. This writer recommended the employment of this serum in affections in the course of which cellular tissue is infiltrated with pus when it is impossible to evacuate it by the usual methods.

The public has been much concerned about the health of Dr. Waldeck Rousseau, ancien président du Conseil des Ministres de France. The disease from which he has long suffered finally came to the surgical stage. Several days ago, Professors Ferrier and Poirier operated in order to reëstablish the free access of the biliary passages. A cholecystenterostomy was performed with successful results. The patient is now in full convalescence.

Among the severe losses to the intellectual world, was the death of Professor Duclaux, director of the Pasteur Institute, and Professor at the Sorbonne. As collaborator of Pasteur, Duclaux had made famous the doctrine of his master. The "Traité de Microbiologie" was his most important work. Duclaux was also the founder and the director of the "Annales de l'Institut Pasteur," a publication which quickly became famous throughout the entire world.

THE ATTENDING PHYSICIAN AND CONSULTANTS.

TO THE EDITOR OF THE MEDICAL RECORD:

SIR: Some remarks on the above subject, made by me from the Chair at the Sloane dinner, have occasioned much debate among my immediate associates. In order to stimulate a much wider discussion which may be profitable I offer them to the numerous readers of the MEDICAL RECORD:

"As this Chair grows in importance it will grow in influence. And what should be he influence of the Chair of an association such this? For the benefit of the members; for the standing of the profession. . . . Thus, it benefits the man, it benefits the community, to get together in cordial coöperation. For what is the highest aim of the medical man but the greatest good for his patient? And how shall he get the greatest good for his patient? By using the best abilities he can get hold of to focus on a difficult point. . . . The greatest man in medicine is not the specialist, but the synthesist—the man who can put several specialists to work, if need be, and use their result.

"Compare the safety of a patient under such charge with the same case under the charge of the little chap who, in an emergency, is bustling about principally to keep a stranger out of his sick-room. . . . This, perhaps, would never occur were not a misty idea on he ubject of consultants in the minds of the laity and profession. I should like to see the prevalent idea modified a bit. Next to the question as to who shall be the consultant, is the question, who shall use the consultant. Shall the family use him to check up the work of the attending physician, or shall the attending physician use this eminent or special ability as he needs it at his weak points? The captain may need a pilot, but it is the captain who needs him, and not the passenger, to inquire if the captain is right. . . .

". . . To get all the credit for pulling a case through is only a subordinate aim of the profession. There is one high, primary aim, the good of the patient. There must necessarily be several collateral aims such as our reputation, our financial return. Sometimes the aims conflict. But, in such cases, it is not only Scripture, but good professional policy, that he who would lose his own life shall find it." . . .

Commenting on the above, I would add: There are about the following attitudes in the community regarding consultations: Physicians who desire consultations and physicians who do not; patients who desire them and patients who do not.

A physician may not desire a consultation because (1) he wishes all the credit for restoring his case; (2) because

he fears a revision of his mismanagement or ignorance; (3) because he fears the unfairness or dishonesty, or overshadowing, of the consultant; (4) or because he wishes to save his patient unnecessary or useless expense.

A physician may desire a consultation (1) because he needs help; (2) because he wishes to divide responsibility; (3) because, in very exceptional cases, he wishes to throw work to a consultant for past or future favors.

A patient, or his friends, may not desire a consultation, (1) because of the expense; (2) because of the prevalent idea of professional ethics whereby one doctor is supposed to be compelled to "back up" another doctor—"and it's just twenty-five dollars thrown away;" (3) and because of the fancied reflection upon the trusted attending physician.

A patient, or friends, may desire a consultation (1) because of a just appreciation of the situation and a wise desire to extend to physician and patient all available help; (2) because of a "foxy" desire to set opinion against opinion; (3) because of a pride, or a hope, or a fear, or a general panic, which would have at the bedside names which—like the leading hatter's label in a hat—proclaim that the best has been had.

All rightly thinking people know the great help of a properly conducted consultation. And it is poor policy for a physician to allow himself to remain without help continuously in charge of a long case, especially if chronic. Continual gazing at so fixed and definite a thing as a primary color will finally give the complementary aspect of that color. Therefore the seeming tireless devotion of the attending physician, on vigil day and night, is simply slowly divesting him of his power to discern and take prompt initiative.

Professional efficiency will surely be raised by giving the attending physician use of the abilities of the consulting faculty; by giving him a medical night-watcher when required; by expecting and requiring him to obey in his own person the laws of mental health and sanity. An intelligent layman—one running a railroad, for example—is quick enough to understand the kind of service he is getting in his family, when the attending physician says: "I want a fresh mind to see this case—a consultant's, my lieutenant's—or my own after twenty-four hours of rest." He may then be expected to discern yellow from blue or green.

EUGENE COLEMAN SAVIDGE, M.D.

INTRASPINAL INJECTIONS; THE MAKING OF A PERMANENT WAY THROUGH THE BONY WALL OF THE VERTEBRÆ TO FACILITATE THEIR REPETITION — SPINAL ANÆSTHESIA PRODUCED IN THIS WAY.

TO THE EDITOR OF THE MEDICAL RECORD:

SIR: While the making of a single injection into the spinal canal, whether intra- or extradural, is a relatively simple undertaking, the frequent repetition of the operation is, to the physician, inconvenient, to the patient more or less distressful. For some time I have had in mind to remove this objection by some little effort of contrivance; and, presently, the idea assuming a workable shape, I awaited for the appearance of a suitable case to apply the principle. The opportunity to do this was recently afforded me. One day—scarcely a week ago—I was summoned in consultation by Dr. T. J. McLaughlin of Jersey City to the bedside of a young man who, having sustained a compound fracture of one leg, had subsequently developed severe tetanus. I found the patient who, immediately after the accident, had been conveyed to St. Francis' Hospital, lying upon his back, the jaws firm set, cervical muscles rigid, and the limbs already stiffening. The temperature, 101½° in the mouth, was slowly rising. It was felt on all sides that something radical should be attempted. We decided, therefore, to inject antitoxin into the spinal cord, depositing the medicament beneath the membranes upon the cauda equina.

Realizing that in all probability we should be obliged to repeat the injection, I proposed the following modification of technique:

1. To make a narrow incision along the side of the spinous process of the fourth lumbar vertebræ, letting a narrow bistoury descend through the soft tissue till its point is halted by the posterior arch (lamina).

2. Profiting by this narrow way, to go down with a long, fine drill and penetrate through the posterior arch to the spinal canal.

3. To insert a small silver tube, provided at its upper end with a round, flat disk, the latter to rest upon the skin, and prevent the protrusion of the lower end of the tube beyond the inferior edge of the opening in the bone, into the spinal canal. This tube to remain permanently in place—for days or weeks, if required.

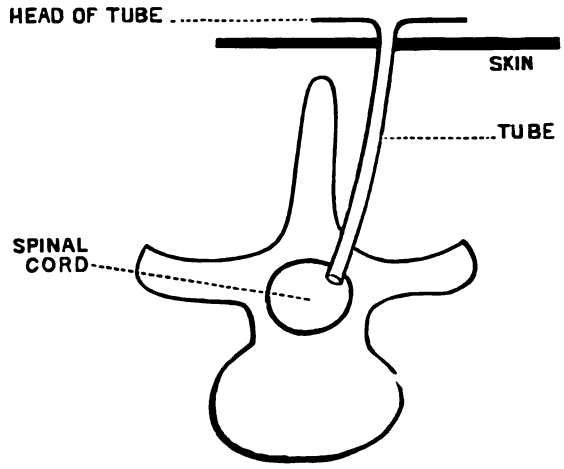
4. By passing a fine, hollow needle, armed with a glass syringe, down through the silver tube, to penetrate the membranes and make the necessary injection. Owing to the fine opening in the membranes, which closes in a few hours, the injections may be made as frequently as desired.

These proposals, received with approbation by Dr. McLaughlin, who coöperated with much zeal, we went forwardly as rapidly as possible.

The patient was quickly etherized, the incision made, the vertebral arch penetrated with the drill, and the silver tube thrust down till its inferor end was about on a level with the posterior wall of the vertebral canal. A long, fine needle, armed with a glass syringe, was then passed down the silver tube, and its point thrust through the membranes—the dura and the arachnoid. In this way about 140 minims of antitoxin were thrown into the subarachnoid space, directly upon the cauda equina.

The hollow needle was now withdrawn from the silver tube, and, in its stead, a stylette with a broad, flat head was immediately inserted. Iodoform gauze—a layer or two—was then interposed between the skin and the flat head of the tube, and between the latter and the head of the stylette. Then more gauze and dressings over all, bands of adhesive plaster passed around the body to keep all in place, and the procedure, which had occupied something over an hour, was completed.

From the ether the patient emerged without incident, and on the following day was able to open his mouth, extend his tongne, and take fluid nourishment. Unfortunately his temper, despite the use of antipyretics, still continued to rise. In fact by the afternoon it lacked



but little of 103° F. It was decided to make another injection. Accordingly about 3.50 P.M. this was done, the amount injected being the same as on the previous day. Despite these heroic measures, supplemented by morphine, chloral, and a liberal use of antipyretics, the temperature still continued to increase, and twenty-four hours later, the mercury standing at 108°, the patient died.

So far as the efficacy of antitoxin in tetanus is concerned, this case is indecisive, the symptoms at the time its services were invoked being so developed as to render any interference little more than a forlorn hope. In recording this brief synopsis of the case, I have desired to make a permanent note of the novel technique employed—of the establishment of a permanent way to the vertebral canal through its bony wall, whereby the repeated introduction of anæsthetics and other agents is made possible without painful searching and prodding between the vertebræ.

A single practical point which I have omitted to touch upon, and I have done. How—and this question will immediately occur to anyone—how shall the length of the silver tube be determined? First, and approximately, by measurements on the skeleton; secondly, and precisely, by inserting into the aperture in the lamina a slender wire armed with a minute blunt hook; the latter, when caught by the lower rim of the orifice, enables one accurately to measure off upon the wire the distance from the posterior aspect of the vertebral canal to the outer surface of the integument. The tube may then be cut off with a file and its edges rounded with a whetstone in a few moments. It is self-evident that antiseptic precautions of the most rigid sort should at all times be observed.

Since the above was written I have produced spinal anæsthesia in this manner.

J. LEONARD CORNING, M.D.

53 WEST THIRTY-EIGHTH STREET, May 31, 1904.

Progress of Medical Science.

Boston Medical and Surgical Journal, May 26, 1904.

Sulphurous Acid and Its Salts as Food Preservatives, as Aids to Fraud, and as Possible Causes of Lesions of the Kidneys.—Charles Harrington describes the effect of sulphurous acid and its salts on vegetables and meat. It bleaches corn and asparagus, while by its use meats are made to acquire the redness of arterial blood. In the treatment of meat, the sodium salt is the compound most commonly employed. Its chief field of usefulness is in the preparation of "Hamburg steak." It acts as a deodorant. Thus, although apparently fresh to the eye and nose, the prepared mass may be well advanced in decay and teeming with bacteria. Sodium sulphite as a preservative is not powerful. The bacterial content of a specimen bears no relation to the amount of added preservative, because much of the material used in manufacture may be swarming with a rich bacterial flora before it is introduced into the hashing machine. For the production of the desired effects, the presence of at least 0.1 per cent. of the salt is necessary, but the addition of 0.2 per cent. is generally recommended. In the stomach, sulphites are attacked by the gastric juice, with liberation of sulphur dioxide. Many animal experiments have been performed with these salts. Nephritis seems to be the common result of its administration.

Notes on Radium.—Francis H. Williams states that physicists now consider that the beta rays from radium correspond to the cathode rays and the gamma to the *x*-rays. The beta rays seem likely to prove a convenient and useful remedy in certain diseases of the eye, particularly those which have not yielded to other methods of treatment. Among these are trachoma, opacity of the cornea, and inflammatory conditions of the neighboring parts. The writer has observed good results follow promptly from exposures of two or three minutes to 50 mgm. of pure radium bromide, given at first once a week and later twice a week. The radium was held about ½ cm. from the everted lid, or was placed even nearer to the closed lid opposite the diseased area. The advantages of radium over the *x*-rays are apparent. The output of the rays from radium is uniform, and the rays may be easily applied. The greatest care should be employed when diseases of the lids or eyes are treated with this powerful agent. Radium is also an excellent test for determining whether or not the eyes of the practitioner are in a suitable condition for making fluoroscopic examinations. The spinthariscope containing a bit of radium is employed. If the scintillations appear bright to the practitioner, his eyes are ready for use; if dull, he must wait for a while longer in the dark room before attempting to make a fluoroscopic examination.

Journal of the American Medical Association, May 28, 1904.

The Cultivation of the Surra Trypanosome of the Philippines.—From the laboratory work at the University of Michigan by F. G. Novy, W. J. McNeal, and C. B. Hare, the following conclusions are drawn: (1) The trypanosome present in the Philippine surra can be cultivated artificially. (2) Attenuated cultures of this organism can be obtained as in the case of *Tr. brucei*. (3) This trypanosome is differentiated by its cultural characteristics from *Tr. lewisi* and from *Tr. brucei*. (4) The Philippine surra is, therefore, a distinct disease, different from nagana, and this observation confirms the work of Laveran and Mesnil on the non-identity of nagana and the surra of Mauritius. (5) The morphological differences between the Mauritian and Philippine trypanosomes suggest the probability that these organisms are distinct species, and hence that the term "surra" covers a group of closely allied diseases.

A Consideration of Speech Defects—J. M. Brown finds that heredity plays little part in this condition. Among primary causes are fear, timidity, ill-treatment, and accident. Imitation lies at the bottom of many cases. All of the various diseases of childhood, especially the infections, and a hereditary history of tuberculosis and insanity may act as causative factors. Modern authors lay particular stress upon the necessity of normal upper air passages. Continuous voice production is the essential of speech. To accomplish this, a strong, unbroken stream of sound is necessary, and no mouth action should be allowed to interfere with the throat sound. There is no trick or particular method that is applicable for the treatment of all cases. If possible, the cause should be first ascertained, and then treatment instituted for ultimate relief. In many cases, the main point to be remembered is the easy passage of air, with attention to the proper placing of the voice, that being the material of speech, and should not be impeded in any way. Training for continuous production gradually enables one to become familiar with all vocal elements. Self observation and control, eradication of the spasmodic actions, together with patience and perseverance, will, in many instances, permanently overcome the distressful, embarassing impediment in speech.

The Prevention of Typhoid Fever.—R. I. Cole declares that to stamp out the disease we must first learn to recognize all cases, and second, must destroy all typhoid bacilli as soon as they leave the patient. A clean water supply is absolutely essential. Typhoid fever often passes unrecognized in children. Notification laws must be rigidly enforced. Many physicians who recognize the necessity of disinfecting the stools are still careless regarding the disposal of the urine. Especially is there carelessness in handling urine in the laboratories where it is being tested. In the dead-house much carelessness still exists. Pathological material is freely handled, but the hands are not disinfected as they ought to be. If the patient is raising sputa the same precautions ought to be observed. For urinary disinfection the author prefers carbolic solution 1–20, or bichloride 1–1000 If the latter is used we should add common salt in the proportion of 0.5 parts to 1,000. Finally, we do not do our whole duty unless we disinfect the bath-water in which the patient may have been tubbed. He occasionally voids in the bath, and there is always danger that small fecal particles may be washed from the anus into the water. This contaminated water is generally thrown into the sewers. Where portable tubs are used the water is often splashed over the floor. Lack of precaution in this respect invites the spread of the disease among attendants, and is undoubtedly the cause of much of the disease arising in hospitals among nurses and orderlies.

Medical News, May 28, 1904.

Results in Diffuse Septic Peritonitis Treated by the Elevated Head and Trunk Position—Russell S. Fowler presents the following salient points in the treatment of these cases: A small incision and the avoidance of eventration; thorough cleansing of the primary focus of infection and removal of the appendix; evacuation and cleansing of all accessory abscess cavities and the pelvis before washing out the peritoneal cavity; a rapid systematic flushing of the peritoneal cavity with peroxide soda solution followed by hot saline; the continuance of the saline flushing until the sutures are placed, and for the most part tied; the provision for proper drainage for the pelvis, either by means of a large glass tube containing a capillary drainage strip emerging through the lower angle of the wound, or, in females, by a large caliber rubber tube filled with wicking passed through a posterior colpotomy incision; the drainage of accessory abscess cavities with gauze or wicking; the elevation of the head of the bed to accelerate the drainage of septic fluid into the pelvis, where it can be removed through the glass tube, or, in case of vaginal drainage, find a ready exit.

A Case of Gastric Cancer.—G. W. McCaskey gives the history of this case. The patient was a man of forty who was suffering from "stomach trouble" of one year's duration. The first symptom was pain after eating, in the region of the stomach, also in the back between the shoulders, especially in the right side. A few weeks later there developed excessive gas formation in the stomach, both this and the pain being most aggravated almost immediately after eating. He had vomited only a few times. Lying down at night gave relief. There was a tendency to constipation, but never any sign of melæna. There was much intestinal gas. The patient had lost about forty-five pounds. The liver was slightly enlarged, but the stomach was not. There was absence of free hydrochloric acid but strong biuret reaction. Lactic acid was present, but no Oppler-Boas bacillus. The blood was concentrated with 6,000,000 red cells at the first examination and 5,500,000 at the second, and about 110 per cent. of the normal amount of hæmoglobin. There were 15,000 leaucocytes at the first examination and 10,000 later. Under treatment the stomach conditions improved somewhat. A few weeks later the stomach symptoms suddenly ceased, the appetite became voracious, and the weight increased thirty-five pounds. But there was not a corresponding approach toward appearance of health. Stomach symptoms returned, however, in three or four weeks. A little later marked jaundice developed and about four weeks before death general dropsy developed. Necropsy revealed neoplasms of both liver and stomach. Anatomical and physiological considerations tend to support the view that gastric cancer was primary though very slow in its evolution, and that the liver was the last organ implicated, since the movement of fluids by which metastatic processes occur does not take place from the liver to the stomach but from the stomach to the liver. The neoplastic formation in the stomach was in the pyloric and cardiac regions, while otherwise the organ was ap-

parently normal. This is a rare distribution. And the disappearance of stomach disturbance, the voracious appetite, and the rapid increase in weight are remarkable phenomena in the case of a patient who died of cancer about three months later.

New York Medical Journal, May 28, 1904.

The Prevention of Blood Aspiration During Operations on the Mouth.—The method of A. W. Herzog consists in intubating the patient and connecting the intubation tube by means of a tightly fitting end-piece with a rubber tube which is passed through the patient's nose, so that the inspired air or anæsthetic is taken into the lungs through the tube passed through the nose. The detailed directions are these: After intubating insert the plug into the end-piece, so as to occlude it and prevent it from becoming clogged with nasal mucus. Pass the rubber tubing, to which the end-piece, is firmly wired, end-piece first, through the nose, and when it shows behind the soft palate, take hold of it by means of a forceps and extract the plug. Then take hold of the end-piece by means of a laryngeal forceps and insert firmly into the opening of the intubation cannula. Thus the larynx is occluded as safely as can be desired. The patient will breathe through the rubber tube and the anæsthetic can be administered in this way as easily as through the tracheotomy tube.

Examination of the Bladder in Twenty Cases of Ventral Suspension.—The case histories are given in abstract by S. Chandler, whose conclusions are as follows: (1) In all cases requiring ventral suspension the bladder should be thoroughly examined by a cystoscope. (2) In no cases reported among this number was there any trouble with frequent micturition after the operation of ventral suspension, except when there was some evidence found which would cause such disturbance. (3) The new position of the bladder after ventral suspension aided and relieved, rather than caused, frequent micturition. (4) The said operation may have caused this relief by removing pressure from the neck of the bladder, which pressure undoubtedly helps to cause frequent micturition. (5) The left ureter opening and surrounding parts were often affected, but the cases are too few to state positively why this existed in these cases. (6) Immediate and prompt treatment saves much suffering and adds much to the surgeon's reputation, and to that of the operation. (7) By examining the bladder and surrounding parts we may find cases in which suffering may be relieved, when for some reason an operation for uterine disease cannot be performed. (8) To make such examination eliminates errors, and is more scientific; and the more exact we become, the firmer ground we tread.

What the General Practitioner Should Know of Ophthalmology.—H. H. Seabrook believes that a general practitioner should be able to handle cases of external inflammatory nature, but he should remember that photophobia, pain, circumcorneal injection, and diminished vision belong not to conjunctivitis but to disease of the eyeball. So, too, a careful watch must be made for iritis or glaucoma. An eyeball harder than normal is glaucomatous, and the increased tension is estimated by feeling the ball through the upper eyelid with the tips of both forefingers, while the patient looks downward. The prognosis is regularly bad without proper treatment, and the best treatment in general is an iridectomy early in the disease. Of the disturbances of motility the squints are evident deformities, the paralyses have double visions or pupillary disturbances, and their study belongs more properly to the department of neurology; muscular insufficiencies belong to cases of eyestrain, soon to be considered. The vision in all cases had better be tested, but for the external inflammatory cases, the diagnosis may often be made easily without this. For internal diseases a test of vision should always be made. The usual methods are described by the author. The use of the ophthalmoscope is difficult and tedious for the general practitioner, and to depend too much on its findings may lead to error. It confirms suspicions rather than establishes a diagnosis. To sum up, the general practitioner should know how to evert an upper lid, because he sometimes ought to know what is upon the conjunctival surface. He should also know that poor sight, double vision, photophobia pain, circumcorneal injection, unnatural pupils, or hard eyeballs are danger signs, in order to be able properly to advise his patients.

American Medicine, May 28, 1904.

Empyema.—De Forest Willard concludes that early diagnosis of pleurisy and early operation are the prime elements in the avoidance of empyema. The general practitioner is the one who needs to be on the alert. A test for fluid should be made with the aspirating needle, not a hypodermic, as the latter is too small and short. Liquid, if present, should be immediately withdrawn; if purulent, further operation within a day or two is advisable as soon as the lung expands and the heart moves toward its normal position. Aspiration should be limited to diagnostic purposes, to the withdrawal of serum, and as a preliminary operation in empyema. In all cases of pyothorax, free drainage, not aspiration, should be the rule. The larger the openings the quicker will cure be effected. Resection of ribs is imperative for exploration by the finger and for removal of fibrinous masses. Washings are counterindicated, except in fetor, and even then more perfect drainage is indicated rather than irrigation. In old chronic cases with contracted lung and degenerated pleura, more or less excision of the chest wall and pleura should be performed, even to the excision of the entire extent of all the ribs. Even in tuberculous empyema, benefit is derived from thorough drainage.

The Santa Cruz Mountains of Jamaica, West Indies, for the Tuberculous.—Logan Russell and Leslie Alexander call attention to the climatology of the Santa Cruz mountains. The best spot for tuberculous patients in the island of Jamaica is Malvern, situated in the Santa Cruz mountains, at a height of 2,350 feet above sea-level. Many patients have gone to the higher ranges of the island, and by abstaining from alcoholic drinks and by leading proper lives, they have recovered and lived to old age. At Kingston the heat is tropical and the dust sometimes excessive, so that that city is not at all suited to patients with impaired pulmonary tissues. But the climate of Malvern is such that the open-air treatment of pulmonary tuberculosis can be pursued without interruption during the whole year. For a distance of over sixteen miles the Santa Cruz range runs parallel to the sea, ending abruptly in the Southfield district with a cliff 1,550 feet high and less than half a mile from the seashore. In no part of its entire extent does the range diverge landward further than eight miles from the sea. "Malvern Heights" is the most central part of the range and offers an ideal climate in which there is a mixture of mountain and ozone-laden air, very dry, and with a most equable temperature. Over a period of ten years, the average minimum temperature has been 63⅓°, the average maximum temperature, 72⅔°, while the average range has been 99°. The average rainfall during the past four years has been only fifty-five inches. During the past ten years, only once did rain fall for three and one-half whole consecutive days—and this was in a year of floods. The rainy months are May and October, though October is rather a month of showers than of rain. Owing to the limestone formation of the range, and consequently perfect drainage, one can enjoy weeks along the well-kept mountain roads within an hour of the heaviest rains. There is no forest land in and around Malvern. The entire range of mountains is a pimento region, a product which grows in open, common pasture where there is absence of shade and humidity. In all throat and lung troubles the climate produces marvels.

Neuritis as a Complication of Some Portion of the Child-bearing Process.—William R. Nicholson, in the discussion of this subject, declares his preference, as far as the etiologic classification is concerned, to be as follows: (1) Those cases supposedly due to some toxæmia. (2) Those cases arising from a septic process. (3) Those cases resulting from some mechanical agent operative during labor or in the early puerperium. These three cases include all cases which can in any way depend upon pregnancy as the causative factor. Myelitis or other diseases of the nervous system may show the first signs during pregnancy, and in such cases the influence of pregnancy is not to be considered as causative except as any other marked strain. Little is known about the toxic group. A number of reported cases are difficult to explain on any other supposition. Sepsis is more often operative during the puerperium than in pregnancy. The principal cause which explains a neuritis in the puerperium with consequent palsy of one leg is a combination of a medium grade of contracted pelvis, usually of the generally contracted variety, together with a presenting part which either with difficulty passes or is unable to be delivered without instrumental aid. As to prognosis, in all probability in a considerable number of mild cases of peripheral neuritis, the patients recover without any diagnosis of the condition having been made, as the period usually spent in bed after delivery would be amply sufficient for this in such cases. In the severer forms, the prognosis is doubtful or good, according to whether the reactions of degeneration are present or not. The symptoms vary according to the severity of the lesion. They vary from a transient pain, often ascribed to rheumatism, to a symptom-complex resembling "Landry's paralysis" or myelitis. The usual type presents some pain, loss of power, perhaps some sensory disturbances as paræsthesia and atrophic changes. The nerves involved are in less

ere cases the median or ulnar, or if the leg be affected, sciatic. the gluteal, and especially the external popal, the peculiar symptom of the latter being the soled foot-drop.

The Lancet, May 21, 1904.

Ankylostomiasis.—J. Chronnell notes that when this ease is once introduced into collieries it is very difficult eradicate. The symptoms are those of a severe form anæmia. In addition, in Cornwall the author's district, irritable pustular skin eruption known as the "bunches" not uncommon. The common tenicide used has been ymol. The author makes a plea for better sanitation collieries.

The Value of Hot-water Injections as a Substitute for trient Enemata in the Treatment of Gastric Ulcer.—Pasteur says that by substituting ten-ounce enemata plain water at 100° F. for the smaller nutrient enemata is possible to prevent thirst altogether and to do away ith the unpleasant taste in the mouth which so often llows enemata containing beef-tea. He begins with x ounces of water as stated and gradually increases ten. Of course this is in addition to the moderate emloyment of the usual substances for rectal nutrition in astric ulcer and is intended only for the relief of roublesome thirst.

Some Experiences in the Surgical Treatment of Suppurave Lesions of the Nasal Accessory Sinuses.—Herbert illey gives the histories of nine cases, describing the arious operations performed and illustrating some of his leas with diagrams. The great questions coming up in ases calling for surgery are what is the danger to life if, rst, nothing is done and, second, if operation is perormed? Danger to life depends on the focal seat of the nflammation. Many cases of meningitis are on record ollowing frontal, ethmoidal, and sphenoidal disease. Retention of inflammatory products in any case leads to epsis with all its dangers. The risk to life from operation lepends on the sinus involved and the surgeon's familiarty with the region on which he is working. Tilley believes hat only obliteration or destruction of the fronto-ethnoidal cells alone offers any prospect of radical cure in his locality. In all this and similar work, the surgeon's notto must be "free, unhindered, and spontaneous drainage." There is no mystery in work in these regions. We merely apply the principles of general surgery to a special region.

Deutsche medizinische Wochenschrift, May 14, 1904.

Immediate Reaction after the Use of the X-Rays.—H. E Schmidt claims that there is an immediate effect from the action of the *x*-rays, which must be distinguished from the ordinary dermatitis which is apt to follow their application after an incubation period varying from one to four weeks. He terms this early reaction, and describes it as an erythema. not uncommon, which is evident in a few hours or less after effective radiation. The phenomenon is independent at the age of the tubes. It appears only in isolated cases, and in these, invariably after every exposure. Apparently the condition is due to some peculiar sensitiveness of the circulatory system for the *x*-rays, in a similar manner as has been shown for psychic, toxic, and thermic influences.

Chronic Diphtheria.—L. Neufeld discusses this condition, which has been recognized as an entity for many years, but to which very few references are found in the literature. The disease takes the form of pharyngeal ulcerations, but their obscure situation often renders them hard to distinguish, or when found they are considered as tuberculous or specific. He believes that the affection is not so rare as seems warranted by the slight attention bestowed by the textbooks. A case is reported in a girl of twenty-one, in whom an apparently uncomplicated angina was followed by an ulcerative process in the pharynx which took five months to heal. A specific diphtheritic process was not observed either during the angina or later. Fever was present only during the angina, which was apparently well in two days. Neufeld includes his case in the group designated by Behring as diphtheroids, which differ from true diphtheria in their clinical course, but are nevertheless due to infection with the diphtheria bacillus. There are probably many cases in which an aborted diphtheritic infection leads to one of these chronic conditions, in which the true diagnosis is not evident until the presence of the Klebs-Loeffler bacillus is demonstrated. A bacteriological examination was also made of a number of cases of atrophic rhinitis and ozæna. It was found that if Loeffler's serum plates were inoculated with the nasal secretion from these cases, other colonies were present under the diffuse growth of the ozæna bacillus. Endeavors to grow the former in pure culture showed that they belonged to the diphtheria group. He does not consider these observations sufficiently extensive, however, to warrant any conclusions as to the etiology of these chronic nasal conditions.

Antethoracic Œsophago-jejunostomy. — L. Wullstein describes a series of operations which he has carried out on the cadaver, and on dogs, but which have not as yet been attempted in the human subject. The first of these, mentioned in the title, is intended especially for benign stenoses of the intra-thoracic segments of the œsophagus, or possibly for carcinoma of the gullet in the region of the bronchus. For the portion of the œsophagus involved in the lesion, it is proposed to employ a section of the gut. This is carried out from the abdominal cavity over the bony thorax and affixed to the chest. The œsophagus is then exposed in the neck, cut through as far down as possible and also attached to the anterior aspect of the chest wall. The space which intervenes between the gut and the end of the gullet is then filled up with a tube made of a skin flap. The most suitable section of the gut for this purpose was found to be that part of the jejunum lying about 30 cm. below the plica duodeno-jejunalis. It is possible to displace the jejunum as far as the fourth cartilage without subjecting it to any marked degree of tension. The plastic flap is taken from in front of the sternum and the right series of costal cartilages. It is inverted so as to make a tube with the skin turned in, and may then be united to the gut below and the œsophagus above. The operation was attempted on dogs, but the hairy lining of the tube, and the difficulty in nourishing the animals, interfered greatly with the success of the procedure. He describes the operation in three stages, in the first of which the jejunum is delivered from the abdominal cavity and fixed to the anterior thoracic wall. In the second the skin tube is formed from the plastic skin flap, and the third comprises the isolation of the œsophagus and its union with the plastic tube. The first and second stages may be done together, but an interval of ten days should elapse between the second and third. Another operation on the same principle is suggested which he calls retropelvic colorectostomy. In this the rectum is brought into direct communication outside the pelvis with the descending colon in the region of the left iliac bone. The indications are not, however, stated.

Berliner klinische Wochenschrift, May 9, 1904.

Two Cases of Gonococcus Sepsis.—P. Krause reports two cases in which it was possible to demonstrate the gonococcus in the blood during life. Only a few are noted in the literature. In the first the diagnosis at autopsy was as follows: Fibrinous pericarditis, endocarditis with ulcerations of the aortic valves, fatty degeneration of the myocardium, pleurisy with effusion, pneumonia, and ascites. Pure cultures of the gonococci were secured from the lungs. Five weeks after infection, symptoms of a general involvement prompted examination of the blood. Twenty c.cm. were secured by puncture from a vein and mixed with glycerin agar. In forty-four hours the characteristic colonies were observed and the diagnosis conformed. Subsequently similar results were obtained. In the second case, a general infection had occurred, as evidenced by the enlarged spleen, pain and swelling in the knee and along some of the ribs on the right side. The infection took place through a perineal tear, sustained during labor, and evidently dated from adouble gonorrhœal pyosalpinx. This patient made a complete recovery, although the gonococci were demonstrated as free in the blood. The author believes that it is possible to find the diplococcus in the blood in all cases in which a metastasis has taken place, but the planting must be done as soon as the fever sets in, and at least 20-40 c.cm. of blood must be abstracted from a vein. The agar should be cooled down to about 40° C., as the gonococci were found to be very sensitive to heat. The colonies are not often even as large as the head of a pin, and care must therefore be taken not to overlook them.

Congenital Absence of the Patella.—O. Heine, in reporting a case of this rather rare condition, finds from a study of the literature that the instances in which the deformity has occurred may be divided into: (1) those in which a patellar deficiency is accompanied by other deformities in the knee-joint. This class also includes those cases in which the patella is absent or very small during early life, but develops more or less in later years. (2) Cases of congenital or hereditary absence of both patellæ, without any other abnormalities in the knee-joint. The author's case belongs in the second group, of which but three instances have been reported. The patient stated that his father and sister had the same deformity. The condition gave him very little inconvenience and he was able to follow his usual occupation. When he attempted to extend or flex his leg at the knee, the quadriceps tendon was seen to slip toward the outer side and gained support in its action from the outer condyle of the humerus, which

was remarkably well developed. This lever action was evidently essential to the quadriceps to enable it to act strongly. Closer study of the cases in this group showed that the deformity in all was hereditary, that the knee-joint was otherwise normal and that its function was undisturbed, and finally, that the quadriceps tendon was extremely well developed, with a corresponding enlargement of the tuberosity of the tibia. The author thinks that the latter may act as substitute for the lack of a patella. It seems, therefore, that the patella is essential to the proper functionating of the extension apparatus of the leg. In the same patient there was also present a congenital luxation, in the right arm, of the head of the radius backward.

Münchener medizinische Wochenschrift, May 10, 1904.

Researches in Hæmoglobin in Chronic Heart Disease.—Schott has made a series of experiments for the purpose of supporting his claim that the treatment of cardiac disease by balneological-gymnastic methods has a tonic effect not only on the heart, but also on the entire organism. The observations were made with Dare's hemoglobinometer, which among others, has the advantage of requiring only a drop of undiluted blood. In order to secure uniformity in the results, the diet was kept unchanged during the observation period, and the readings were always made a certain time after meals. Altogether 120 patients were under continuous observation, in a number of which the results are described in detail. It was conclusively shown that in the most varied cases of heart disease, the employment of these therapeutic measures was followed by an increase in the previously diminished hæmoglobin content of the blood. Schoott finds that the increase takes place much more readily in young and middle-aged persons than in those of advanced years. There is also a group of very interesting cases, in which, during the course of the treatment, there is found a diminution in the hæmoglobin content. This was proved to be the result of too vigorous bodily exertion or severe mental disturbances, but especially in intercurrent diseases accompanied by fever. For the sake of completeness it is proper that hæmoglobin estimates also be supplemented by counts of both the red and the white blood cells. This takes a great deal of time, however, and is difficult to carry out in everyday practice.

Light Treatment by Tappeiner's Method.—Jesionek discusses the therapeutic applications of fluorescent substances in various diseased conditions. The method in general consisted in painting the skin with solutions previously demonstrated in the laboratory to be fluorescent, and then exposing the patient to the sunlight, in the open air, or a specially constructed room. The electric arc was also employed, but was very inefficient when compared with the other. The reacton was found to be entirely dependent on the intensity of the light, so that it became advisable to resort to lenses in order to concentrate the light. In order to avoid the heat rays hollow lenses were used which could be filled with fluids of such a character as to permit only those rays to filter through which were known to be effective in producing fluoresence in the substances employed in the treatment. Thus in a case of solution eosin was used, the lenses were filled with a solution of copper sulphate and picric acid. Eosin was mostly used, and in a watery solution, varying in concentration from 0.01 to 5 per cent., the weaker being found the best. When the crusts became impregnated with the stronger solutions the action of the rays was found to be inhibited, and it seemed, moreover, that the growth of healthy granulation tissue and the production of scars was interefred with. In addition to repeated applications of the eosin solution externally, parenchymatous injections of 0.1 to 0.01 per cent. solutions were employed in carcinomatous growths. The latter method did not seem to possess any special advantages, however, and possibly the injected solution may form a barrier in the deeper layers to the passage of the light rays. During the time when the patients are not exposed to the light, the skin areas should be covered up with boric acid compresses or xeroform powder or ointment. No clinical results are mentioned in this paper, which is merely devoted to technique.

French and Italian Journals.

Occipital Neuralgia in Ordinary Angina.—H. Vincent declares that occipital neuralgia is relatively frequent in the course of catarrhal, ulcerative, or phlegmonous angina. The writer has made a careful study of the nerves of the part and states that there exists in a certain number of subjects an abnormal connection between the pharyngeal nerve and the second posterior root, of which the occipital nerve of Arnold is only the immediate prolongation. This anastomosis, more or less complete, explains the solidity that is sometimes noted between the two branches emanating from the second posterior cervical nerve: the occipital nerve and the nerves of the pharynx. This peculiarity is not constant. The painful radiations sometimes observed at the level of the temple and the neck, are due to the anastomosis of the occipital nerve with the mastoid nerve.—*La Presse Médicale*, April 30, 1904.

Treatment of Carcinoma of the Stomach.—Docq declares that there is no specific treatment for cancer of the stomach. The only treatment for cancer, at least during the first period, and even the second, is surgical intervention. The difficulty in the beginning is to make the diagnosis of the growth. Nevertheless, the blood examination, a test-breakfast, anorexia, pain, constipation, loathing for meat, and sometimes the color of the skin, offer serious indications. It is often too late, when the patient seeks the physician, for any kind of treatment. Soft food, together with the administration of chlorate of soda, is indicated. The chlorate of soda is made up in a quantity of 40 grams to 600 grams of distilled water. The patient takes four or five teaspoonfuls in soup, daily. In the last stage, morphine offers relief, even if the patient is doomed to certain death.—*Gazette de Gynécologie*, May 1, 1904.

Subcutaneous Painful Tubercle in the Region of McBurney's Point.—Félix Mathieu reports two cases of this nature. The first patient was a woman of thirty-five years, the second a man of thirty-nine The woman, three months after an attack of appendicitis which lasted a week, discovered in the right flank a subcutaneous tumor. It was the size of a kidney-bean, round, non-adherent to the skin, and extremely painful to pressure. The writer diagnosed it a subcutaneous tubercle, in a state of irritability. The man had felt dull, intermittent pains in the right iliac fossa for eighteen months, and at long intervals severe griping. It had been diagnosed as chronic appendicitis. One day he discovered a subcutaneous tumor at McBurney's point. The tumor was the size of a pea. Pressure caused extreme pain, compared by the patient to that of a dental nerve hit by a probe. This patient had suffered from chronic lumbago with pains in the abdominal walls, hemorrhoids, and habitual constipation.—*Gazette des Hôpitaux Civils et Militaires*, March 24, 1904.

Axillary Adenitis and Mammary Adenoma.—Jeanne of Rouen has made a study of axillary adenitis associated with adenoma of the breast. After specifying that he attaches to the word adenoma only a purely clinical significance—an encapsulated benign tumor—he reports two cases in which adenoma of the breast was accompanied by axillary adenitis, a symptom habitually regarded as pathognomonic of cancer of the breast. The ganglia, nevertheless, were not very hard, and were freely movable. They were, besides, painful. In one of the patients the evolution of the adenoma was particularly interesting, developing in the midst of inflammatory phenomena (painful swelling, tension, and redness of the skin, voluminous adenitis), lending credence to the belief that the lesion was an abscess. Jeanne recalls the theory, upheld by Delbet among others, that adenofibroma of the breast is of an inflammatory nature This theory depends solely upon his biological and bacteriological proofs. These cases here reported give the clinical sanction.—*Archives Provinciales de Chirurgie*, May 1, 1904.

Contribution to the Study of the Cystitis Caused by the Colon Bacillus in Infants.—Carlo Comba states that this disease is far from rare in infants and children, especially in early infancy. In older children, from five to eleven years, it is less serious; the fever is slight, there is uneasiness over the bladder, and a light cloud in the urine, the reaction of the urine is acid, albumin is scarce or absent; microscopically there are present bladder cells, polynucleated leucocytes, and many short, mobile bacilli, in small masses, which correspond to the colon bacilli. The course of the disease is short and the recovery good. From birth to three years the disease is much more serious; the fever is high, up to 40° C., remittent or intermittent in type; there is thirst, anorexia, vomiting, and general failure of health. Intense pallor may be present, and somnolence alternating with great irritability. The urine is frequent and painful, contains albumin, cells from the urinary passages, and colon bacilli. The course of the disease is long and severe, and there may be extension to the kidneys. The question comes up as to how the bacilli enter the bladder. There are three modes of entrance; hæmatic, which is very rare; intestinal; ureteral, which is most frequent. The author describes a case that was very severe in its manifestations, treated successfully with the Celli-Volenti anticolic serum by hypodermic injection. Injections of protargol into the bladder were also used. Comba thinks that in this case resistance was weakened by the presence of too much uric acid, which produced a mild cystitis, and this was aggravated by the presence of the bacillus coli in the urine. After the use of the serum he found by microscopical examination of the urine that many of the bacilli had lost their motility.—*Revista di Clinica Pediatrica*, April, 1904.

Contribution to the Influence of Altitude upon Diseases of the Heart.—Giovanni Galii has observed several cases of heart disease which have done well at high altitudes, quite contrary to the ordinary opinion. One of these had arteriosclerosis and myocarditis, with an old hemiplegia and aphasia resulting from an apoplectic attack of two years' standing. This gentleman insisted on going over a pass in Switzerland having an altitude of 2,341 meters, and remaining some time in the mountains. No ill effects were observed from the altitude. Later the writer observed six other cases, two of irritable heart, two of aortic insufficiency, one of arteriosclerosis, and one of myocarditis. These were all able to remain some time at an altitude of 1,168 meters. The transitory ill effects of the ascent soon passed off, and the patients seemed rather benefited than otherwise by the altitude.—*La Riforma Medica*, March 23, 1904.

Pathogenic and Clinical Study of Hydrosalpinx.—Jacques Delage states that primary hydrosalpinx often accompanies fibroma of the uterus. The coexistency of a secondary hydrosalpinx, coincident with a catarrhal or suppurative salpingitis of the opposite tube would lead to the hypothesis that it is developed under the influence of a hyperæmia of the mucosa. Experimentally, in tying the tube at two points distant from each other there will be produced a purely serous hydrosalpinx. As to the treatment of this affection, laparotomy is advised. The vaginal route should be systematically rejected. The treatment may be conservative or radical. Resection of the tube may be practised when the hydrosalpinx is limited to the most internal part. Salpingostomy followed by salpingoplasty may also be used. Supravaginal abdominal hysterectomy may be performed, leaving the ovaries in place if they are in good condition, removing them if they are diseased. The writer believes that in these cases the uterus should be sacrificed.—*Archivés Générales de Médecine*, April 19, 1904.

A Case of Pneumococcic Peritonitis.—G. Panzacchi reports a case of peritonitis in which the pneumococcus figured as the cause. Such cases are rare. The patient, a girl of twelve years, was taken suddenly with violent pains in the abdomen. This sudden onset is characteristic of pneumococcus peritonitis. She had severe vomiting and high fever, with irregularity of the bowels. After fifteen days the vomiting ceased and the symptoms lessened. There still remained tenderness over the abdomen, and a swelling below the umbilicus, with evening rise of temperature. A laparotomy was done, and the swelling was found to be due to a large collection of fetid, greenish pus, four litres in amount, which was walled off from the abdominal cavity by adhesions. Examination of the pus showed Frënkel's pneumococcus. This was also found in the blood and in the peritoneum. The pneumococcus must enter by means of the circulation. It cannot enter by the lymphatics, for the lesion is usually situated in the lower part of the abdomen, below the umbilicus. It does not enter through a normal intestine, for the acid gastric juice would destroy the cocci. Hence the author believes that it usually enters by the blood. The mortality is great, 76 per cent. It is more frequent in women than in men.—*La Riforma Medica*, April 13, 1904.

A Case of Puerperal Infection in the Country.—L. J. Trudeau gives the history of this case. His patient had been confined twice previously without serious complications. Forceps, however, had to be used. But at the last confinement the patient, who had suffered considerably during the last month of pregnancy, complained of headache and pain in the lower abdomen the second day after labor. As the writer lived at some distance from his patient, he instructed the husband of the woman how to give vaginal douches of boric acid. Two days later, however, the patient was worse. The pulse was 120, the temperature 103, the lochia almost nil and fetid. The writer gave the patient an injection, and her condition became much more hopeful For several days there was the same history—improvement after treatment by the physician, while alarming symptoms followed the douches given by the patient's husband. In spite of the care of the writer, the patient died with all of the apparances of puerperal infection. The cause then came to light. The husband who was a farmer, owned a number of cows. Two of the animals were suffering with puerperal infection, and their owner gave them the same treatment that he gave his wife, using the same instruments without disinfecting them. The writer calls attention to the lamentable ignorance of the very elements of hygiene which exists in the country —*L'Union Médicale du Canada*, May, 1904.

Contribution to the Study of Foreign Bodies in the Respiratory Apparatus.—Camillo Vittorio Pich writes that foreign bodies entering the respiratory apparatus, if angled or pointed, may fix themselves in the mucosa of the upper air passages so that they cannot be easily displaced, when they cause great and urgent dyspnœa. If round, they tend to change their position with respiration and coughing. They may pass the glottis and enter the trachea and bronchi. If loose in the trachea, they may rise with each respiration. Symptoms of suffocation may supervene at once. If they remain in the larynx the symptoms are most urgent; in the trachea they are better tolerated; while in the bronchi the symptoms caused are slight and obscure. He records three cases observed by him. In the first a kidney-bean became lodged below the rima glottidis. In the second he found symptoms of dyspnœa present with no lesion of heart or lungs demonstrable. On auscultation there were vibrations, most intense in the neck, and rhonchi. He could see a small rounded body below the cords, which proved to be a small grain seed. In the third case the dyspnœa was severe, rough respiration over the right lung, rhonchi, the sound as of a valve closing and opening with respiration. After a severe attack of coughing a small, white, solid mass was expelled, the size of a small nut, which had a hard center and proved to contain some whitish cylinders of confectionery. Relief was immediate. He concludes by saying that if symptoms are urgent the method of Dupuy-Lorent should be used. If in the larynx or upper trachea, the foreign body may be extracted by the use of cocaine. If a certain diagnosis cannot be made it is better to wait before using surgical interference.—*La Riforma Medica*, March 30, 1904.

Treatment of Cancer of the Skin by X-rays.—Leredde believes that radiotherapy constitutes an excellent curative method in cases of cancer of the skin—very often preferable to any other. The technique now in use allows the employment of the *x*-rays without danger to the patient, and with the result that in the majority of cases rapid improvement and cure are attained in a few sittings. The forms of this affection which especially succumb to this method are epitheliomata in the adult. They are the serious cases of epitheliomata or those which have a tendency to become serious. The cure is brought about by the disintegration and liquefaction of the diseased tissue, which is eliminated in an integral manner, demonstrating the elective action of the *x*-rays on epitheliomatous tissues. In cases in which there has been pain it often disappears after the first treatment; likewise the foul odor. The æsthetic results are excellent. The cure is definite when the treatment has been sufficiently energetic. The difficult cases are those in which there exists a marked hyperkeratosis. Radiotherapy may be combined with other curative methods. At the present it may be stated that it constitutes the method of choice in cases of destructive epithelioma of the nose, and in the greater number of cases in which the patient refuses surgical excision.—*Archives Générales de Médecine*, April 5, 1904.

Pyelonephritis of Pregnancy.—Léon Kendirdjy declares that the diagnosis of pyelonephritis in pregnancy is easy. The seat of the pain and the presence of pus in the urine are sufficient to attract attention to the condition of the kidney. Frequent and painful micturition may make the physician think of a cystitis, but exploration of the bladder will often show that its normal capacity has scarcely been diminished. Sometimes, however, cystitis may also exist. It may be primary or secondary, making the diagnosis doubtful. It would be necessary then carefully to note the abundance of suppuration, the location of the pain, the results of palpation and, finally, the intermittence of the pyuria. This last factor itself will clear up the diagnosis. The microscopical examination of the pus made from both the cytologic and bacteriologic point of view will clear up the state of the renal parenchyma and the nature of the pathogenic agent. Pyelonephritis in pregnancy is a benign affection. Almost always the pus disappears from the urine either in the course of pregnancy or some days after labor. Suppuration may persist after the expulsion of the fœtus, and it is then that the prognosis ought to be reserved in relation to the future of the affected kidney. The writer has observed death in only two cases out of sixty-two which have come under his notice. The prognosis in regard to the infant is not so happy. In the immense majority of cases pyelonephritis of pregnancy ceases spontaneously after the uterine contents have been expelled. The ureter being no longer compressed by the gravid uterus, recovers its permeability, the drainage of the kidney is assured, and the pyelitis disappears in a few days. Medical treatment consists principally of rest in bed, the milk régime, the use of diuretics, and of urinary antiseptics. The induction of premature labor has been performed in one case. Surgical treatment includes vesical distention, nephrotomy, and nephrectomy.—*Gazette des Hôpitaux Civils et Militaires*, April 16, 1904.

Book Reviews.

PAIN AND ITS INDICATIONS. An Analytical Outline of Diagnosis and Treatment. By EDWARD C. HILL, M.S., M.D., Medical Analyst and Microscopist; Professor of Chemistry in the Medical and Dental Departments of the University of Denver; Attending Physician to St. Anthony's Hospital, Denver; Author of "A Text Book of Medical Chemistry." Chicago: G. P. Engelhard & Company, 1904.

THE consideration of pain according to the region of the body in which it is found, is rather an unusual method of treatment, but it is none the less interesting. The writer in his preface calls attention to the varieties of regional pains and the consequent difficulty of differentiation and of rational causal treatment. The text deals with all sorts of pains, which are arranged systematically for comparison. In the introduction, the writer differentiates local inflammatory pain, general pain, local non-inflammatory pain, referred or reflex pains, neuralgic pain, hysterical pain, traumatic pain, pressure pain. The first chapter deals with headache of various kinds and from various causes, with suggestions concerning treatment. Chest pain, backache, abdominal, pelvic and genito-urinary pain are the topics of various chapters. The book is full of suggestions and will fill a valuable niche on the reference shelf.

AN ESSAY UPON THE GENERAL PRINCIPLES OF PREVENTIVE MEDICINE. By W. WAYNE BABCOCK, M.D., Lecturer on Pathology and Bacteriology, Medico-Chirurgical College, Philadelphia; Pathologist, Kensington Hospital; Assistant Pathologist, Philadelphia Hospital, etc. Awarded the first prize of one thousand dollars in the competition instituted by The Maltine Company. Reprinted from the *Brooklyn Medical Journal*, January–August, 1903.

AN ESSAY UPON THE MEDICAL INSPECTION OF SCHOOLS: A Problem in Preventive Medicine. By LEWIS S. SOMERS, M.D. Awarded the second prize of five hundred dollars in the competition instituted by the Maltine Company. Reprinted from *The Medical News*, January 17 and 24, 1903.

MUCH interest was taken in the outcome of this plan for competitive essays on preventive medicine, and the results have not been disappointing. The paper on the general principles of preventive medicine, considers the subject under three heads: the factors of disease; the diffusion of the parasites of diseases; and the inhibition of the factors in disease. The essay on the medical inspection of schools is much shorter and is not subdivided. Both monographs embody the latest researches in the subjects treated.

ELETTRICITÀ MEDICA, ELETTROTERAPIA—RAGGI RÖNTGEN—RADIOTERAPIA—FOTOTERAPIA—OZONO—ELETTRODIAGNOSTICA. Pel Dr. A. D. BOCCIARDO, Assistente ordinairo all' Instituto di Clinica Medica della R. Università di Pisa. Con 54 incisioni e 9 Tavole. Milano: Ulrico Hoepli, 1904.

THIS little hand-book deals in a clear and simple manner with the various problems of electricity as applied in medicine and discusses the subjects of electrotherapy, the *x*-ray, radiotherapy, phototherapy, ozone, and electrodiagnosis. It is a convenient guide in the practice of electrotherapy. The author has written from a fund of experience, which he has acquired during the practice of many years. The text is embellished with fifty-four cuts, many of them representing the machines in use at the present day. There are also tables with illustrations showing the position of the various muscles and nerves.

LA RACHITIDE E LE DEFORMITÀ DA ESSA PRODOTTE, con 116 Figure intercalate nel Testo. Pel Dr. PAOLO MANCINI. Milano: Ulrico Hoepli, 1904.

THE subjects discussed by the author cannot fail to be of value to physicians in general. So much is included in their consideration that they are of almost universal interest. The etiology and pathogenesis are first discussed with the various theories that have been advanced. The pathological anatomy, chemical alterations in the bones, and anatomical changes in the organs which have been noted in this disease, follow in order. The writer then devotes considerable space to the deformities incident to this malady. The chapter on diagnosis deals mostly with differential diagnoses. After touching on the prognosis of rachitis, the author deals in the last part of his work with the treatment of the various manifestations of this malady. One hundred and sixteen cuts are scattered throughout the text. An elaborate bibliography is appended. The book, though so compact in form, will prove of much value to physicians.

NOUVEAU FORMULAIRE MAGISTRAL. Par A. BOUCHARDAT, Professeur d'Hygiène à la Faculté de Médecine de Paris, Membre de l'Académie de Médecine, Président d'honneur de la Société de Médecine publique et d'Hygiène professionnelle; G. BOUCHARDAT, Membre de l'Académie de Médecine, Professeur à l'Ecole Supérieure de Pharmacie de Paris, Agrégé de la Faculté de Médecine de Paris. Trente-troisième édition. Paris: Félix Alcan, 1904.

THE thirty-third edition of this compact little manual has been brought completely up to date. Many additions have been made. A table giving the principal ones is placed after the preface. The section treating of diet in various diseases is full of valuable suggestions. The indexes both of author's and of contents make the volume a most convenient one for reference.

TECHNIQUE DU MASSAGE. Par le Professeur J. ZABLUDOWSKI, Directeur de l'Institut de Massage de l'Université Royale de Berlin. Traduit sur la deuxième edition allemande par A. Zaguelmann. Avec un atlas de 80 figures. Paris: G. Steinheil, 1904.

THIS volume of 146 pages is divided into three sections: (1) General Technique of Massage; (2) Methods of Massage with Apparatus; (3) Massage of Organs. Appended to the text is a series of 80 illustrations which show the author's methods of work as no description could possibly do. These begin with a cut illustrating the massage of flat-foot. There is a full and clear description below every cut. The various parts of the body are taken up one after the other for discussion. Such practical points as the suitable ointment for massage, the proper temperature for the operating room, position of the physician in relation to the patient, precautions necessary for the avoidance of pain, the duration of the entire treatment, hour of the day for massage and massage of pregnant women are all carefully discussed. The book is most attractive and is a decided addition to the literature on this subject.

LA MÉDICATION SURRÉNALE. Par les Docteurs R. OPPENHEIM and M. LOEPER, Anciens Internes des Hôpitaux de Paris. Paris: J. B. Baillière et Fils, 1904.

THE authors first consider the preparation of the suprarenal extracts used in experimental medicine, their toxicity and physiological effects. The dosage of the different praparations is then discussed. The latter half of the work is devoted to the consideration of the therapeutics of these extracts. Their value as a cardiotonic, hæmostatic, antiphlogistic, and anæsthetic. The concluding chapter deals with suprarenal medication in Addison's disease.

PRÉCIS D'ANATOMIE DENTAIRE. Par J. CHOQUET Chirurgien-Dentiste, D.E.D.P. de la Faculté de Paris Professeur suppléant à l'Ecole dentaire de Paris. Paris: F. R. de Rudeval, 1903.

THE writer in his preface states that his object in presenting this book has not been to offer an absolutely exhaustive treatise on this subject, but rather a volume which will prove useful to the student of dentistry or of medicine, or even to the general practitioner by giving a sufficiently detailed review of this subject. The value of the work is greatly enhanced by the cuts with which it is embellished. These have been made from original drawings, photographs, and photo-micrographs. The volume teems with original work and well fulfils the purpose for which it was written.

FATIGUE. By A. Mosso, Professor of Physiology in the University of Turin. Translated by MARGARET DRUMMOND, M.A., and W. B. DRUMMOND, M.B., C.M., F.R.C.P.E., Extra Physician, Royal Hospital for Sick Children, Edinburgh; author of "The Child, His Nature and Nurture." New York: G. P. Putnam's Sons; London: Swan Sonnenschein & Co., Ltd., 1904.

THE name of the author of this volume is a sufficient guarantee of its value and interest, and the reader is not disappointed in perusing the pages. In the chapter on "Lectures and Examinations" there is a convincing series of experiments demonstrating the relation between cerebral and muscular fatigue. This work is most important in relation to school curricula. An obvious practical conclusion is that games, or any form of athletic exercise should not be forced upon students during any time of special intellectual strain. The writer shows the importance of a quiet situation for schools; he proves experimentally that the time of perception is lengthened by noise. Again the author demonstrates that the best results are obtained by alternating short periods of work with play. Of the many instruments which of recent years have been invented to record and measure the vital and mental processes one of the most important is Mosso's Ergograph or Fatigue Recorder. Most of the writer's conclusions are based upon experiments which he has performed with this apparatus. Among the subjects touched on are The History of the Study of the Movements of Animals, The Origin of the Energy of the Muscles and of the Brain, The General and Special Characteristics of Fatigue, The Law of Exhaustion, Attention and Its Physical Conditions, The Method of Intellectual Work and Overpressure. This volume is a most interesting and valuable addition to educational works.

LES ACTUALITÉS MÉDICALES. TRAITEMENT CHIRURGICAL DES NÉPHRITES MÉDICALES. Par le Dr. A. POUSSON, Professeur agrégé à la Faculté de Médecine de Bordeaux, Chirurgien des Hôpitaux de Bordeaux. Avec 7 figures dans le texte. Paris: J. B. Baillière et Fils, 1904.

THE writer has compiled this little volume, believing that it will be of value to those interested in this subject. The question of the surgical treatment of Nephritis has been so warmly discussed of late years by both its advocates and its opponents that the present work is most timely, as it presents a general résumé of the whole subject.

LES ACTUALITÉS MÉDICALES. DIAGNOSTIC DE L'APPENDICITE. Par le Dr. MAURICE AUVRAY, Professeur agrégé á la Faculté de Médecine de Paris, Chirurgien des Hôpitaux de Paris. Paris: J B. Baillière et Fils, 1904.

THE writer calls attention to the paramount importance attaching to the diagnosis of appendicitis. Much interest has been taken in late years in the treatment of this disease, but the author believes that if more knowledge were possessed by physicians in regard to the diagnosis there would not be so many avoidable errors made by clinicians of the best standing. The book is well written and of much value.

A SYSTEM OF PRACTICAL SURGERY. By Profs. v. BERGMANN, v. BRUNS, and v. MIKULICZ. Translated and edited by Drs. W. T. BULL and WALTON MARTIN. Vol. I, The Surgery of the Head. New York and Philadelphia: Lea Brothers & Co., 1904.

THIS monumental work, conceived and executed by three of the greatest surgeons in Germany has attained the distinction of a second edition in its own land and of a contemplated translation into several other languages. It is in the form of a manual and is intended to occupy a position among German writings on surgery intermediate between the well-known collection of monographs published as the "Deutsche Chirurgie" and the more or less elaborated textbooks. It is intended to serve the general practitioner as well as the surgical specialist with a means of reference which shall be applicable at the bedside and in the study. The herculanean task of bringing out this work in the English language has been entrusted to Dr. Wm. T. Bull, Professor of Surgery at the College of Physicians and Surgeons, New York, and associated with him in the translation of the first volume is Dr. Walton Martin. This volume takes up the surgery of the head, and its various chapters have been written by specialists in their fields—v. Bergmann, Krause, Krönlein, Kummel, Kuttner, Lexer, Schlatter, and Wiesmann—men of acknowledged authority and large clinical experien e. In each subdivision the pathological data, the symptomatology and treatment are very fully considered, and the details of original research and statistics presented by individual authors in connection with the subject assigned to them, give to many of the chapters the character of authoritative monographs. Personal opinions are not insisted upon and the polemical discussions so frequently met with in German books, are wisely omitted, so that the work remains as a practical manual of reference which affords to the reader a trustworthy guide to the best and most recent methods of surgical practice.

The translation is free and literal, but too often the German idiomatic constructions are, unfortunately, very faithfully followed, to the detriment of brevity and clearness. The book is well printed and supplemented by a complete and satisfactory index. The illustrations are numerous and the greater proportion well executed, but many have seen previous service to such an extent that they might well have been retired when this book was printed. The bibliographies which constituted a valuable and important feature of the original German edition, are unfortunately omitted from the American translation. Foreign works are often considered of doubtful value when introduced into this country. This may be true in many instances, but in this case it may well be said that if the remaining volumes round out the promises held forth by this one, the work will occupy a high position as surgical manual and will form a most valuable addition to the armamentarium of the practising physician.

LECTURES, CHIEFLY CLINICAL AND PRACTICAL, ON DISEASES OF THE LUNGS AND THE HEART. By JAMES ALEXANDER LINDSAY, M.D., F.R.C.P. (London), M.A., Professor of Medicine Queen's College, Belfast, Physician to the Royal Victoria Hospital, Belfast, etc. New York: William Wood & Company, 1904.

THE series of twenty-one lectures contained in this volume deal with most of the phases of intrathoracic disease that come under the observation of the physician. The various subjects are not taken up in a systematic manner, but they are discussed in a practical fashion from the clinical standpoint. The actual consideration of the diseases in question is preceded by a brief description of diagnostic methods, a discussion of the interpretation of the history in relation to disease and also a recital of methods of physical examination and of the results yielded thereby. Ten lectures are devoted to diseases of the lungs and pleura, and five of these deal with the subject of pulmonary phthisis alone. An additional lecture takes up the causes and management of hæmoptysis. The various disorders of the heart are discussed in seven lectures, an additional lecture dealing with the physical examination of the blood-vessels. The text is supplemented by an index of authors and a general index. We have here presented a considerable mass of facts in an interesting and instructive manner. The type is large, the paper heavy, and the binding neat.

LESSONS ON MASSAGE. By MARGARET D. PALMER, Masseuse and Manager of the Massage Department of the London Hospital; Instructor of Massage to the Nursing Staff of the London Hospital; Member of the Council of the Incorporated Society of Trained Masseuses. Second edition. New York: William Wood & Company, 1904.

THE author of this valuable work pays special attention to the anatomy of the parts, for after the opening chapter, in which she considers the history of massage, the preparation of the bed and patient, lubricants, and the definition and classification of movements, she makes a study of the human body in its various aspects, beginning with the skeleton. Massage of the various regions of the body is described, one chapter being devoted to the treatment of affections of special parts, such as stiff joints, lawn-tennis arm, writer's cramp, flat-foot, sciatica, varicose veins, etc. The author touches on spinal curvature. Massage of children is considered by itself, including the consideration of infantile paralysis, greenstick fractures, separation of epiphysis, talipes and intussusception. In this new edition a few alterations and additions have been made, besides the chapters on the Nauheim treatment, and bandaging. Some of the old photographs have been replaced by new ones, while two colored plates and other illustrations have been added. The writer has had many years of experience both in teaching and in practical work.

L'ENTÉRO-COLITE MUCO-MEMBRANEUSE. Par le Dr. FROUSSARD. Paris: A. Maloine, 1904.

IN the present monograph Froussard describes the symptom complex of membranous enteritis and its treatment. The writer does not believe that this malady is especially apt to be complicatied with appendicitis. The latter is occasionally met with here, but is not caused by the membranous enteritis, and exists independent of the other disease. As a therapeutic measure of great value, Froussard considers the olive oil enemas of Kussmaul and Fleiner. The small volume will be read with interest by the practitioner.

INFECTION AND IMMUNITY, with Special Reference to the Prevention of Infectious Diseases. By GEORGE M. STERNBERG, M.D., LL.D., Surgeon-General U. S. Army (retired), Ex-President of the American Medical Association, and of the American Public Health Association; Honorary Member of the Epidemiological Society of London, of the Société Française d'Hygiène, of the Royal Academy of Medicine of Rome, etc. New York: G. P. Putnam's Sons. London: The Knickerbocker Press, 1903.

THE importance of this work can hardly be overestimated. The name of the author is a guarantee of its excellence and scientific accuracy. The leading part that preventive medicine is playing of recent years makes any knowledge on this subject of great interest. The writer has stated the main facts as far as they are now known in reference to infection and immunity in order the more clearly to point out the measures necessary for the prevention of infectious diseases. The book is intended for non-medical readers, and with this purpose in view the use of technical terms is avoided as far as practicable. When these terms have to be used, they are explained. A discussion of the theories of immunity and the results of recent work in relation to the "antitoxins," "agglutinins," "precipitins," "bacteriolysins" and so forth, have not been incorporated in the text, as such discussions involve the use of many new technical terms. The writer in his preface expresses the hope that this book may serve, at least to a certain extent, as a textbook in high schools and colleges. The volume is divided into two parts. In the first are arranged the general subjects of Infection, Channels of Infection, Disinfection, Sunlight as a Disinfectant, Natural Immunity, Acquired Immunity, and Antitoxins. The second part is devoted to the consideration of the most important infectious diseases and the manner of their propagation, their importance as a factor in mortality statistics, and the best methods of restricting their dissemination. The book is written in a charming style, and is sure to prove of great value to all interested in the subject of sanitation.

Society Reports.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

One Hundred and Eighty-eighth Regular Meeting, Held May 6, 1904.

Dr. CHARLES STEDMAN BULL, PRESIDENT, IN THE CHAIR.

A Case of Giant-celled Sarcoma of the Lower Jaw Treated by Radium.—By Dr. ROBERT ABBE. This patient had already been shown at the March meeting of the society, and a preliminary report of the case was published in the MEDICAL RECORD, April 30, 1904, page 715. The growth, which was an extensive giant-celled sarcoma of the lower jaw, was first noticed by the patient six months ago. It extended from the middle toward the left, bulging inward under the tongue and outward under the skin—the inner part comprising one-third of the mass, and the outer two-thirds. The diagnosis of pure giant-celled sarcoma was confirmed pathologically.

As the case, surgically treated, called for resection of the jaw, with hopeless mutilation and inevitable recurrence, Dr. Abbe decided to try the effect of radium. A small glass tube of 10 cgm. of the 300,000 *x*-Curie radium was applied over the growth within the teeth for one-half to one hour daily, a lead shield protecting the tongue. Under this treatment, the entire bulk of the projecting internal tumor was considerably reduced. Subsequently the tube was inserted directly into the mass of the tumor and allowed to remain imbedded for two or three hours at a time. By this treatment the growth of the tumor had not only been arrested, but there was an appreciable shrinkage in its bulk during the first two months.

A week after the above preliminary report was made, Dr. Abbe said a small slough appeared on the inner surface of the neoplasm. This, he thought, was the result of overradiumization. The treatment was discontinued, and within a few days a severe dermatitis of the skin and subcutaneous tissue developed over the site of the tumor. This was rather unexpected, as the view was generally held that the skin was never affected when the radium was buried in the tissues or applied internally. This dermatitis persisted for over three weeks, and then, under the use of soothing applications, it gradually subsided. No applications of the radium had since been made, but the improvement in the malignant condition had steadily continued. There was apparent arrest of development of the growth, and a marked shrinkage in its bulk.

Dr. Abbe said that at a subsequent meeting he would report the final outcome of the case.

Dr. GEORGE L. PEABODY said the appearance of the case had certainly improved since it was first shown, two months ago. The tumor was smaller, and its bony walls, which were then very thin, had apparently grown firmer. The development of the new bony tissue, as well as the shrinkage in the size of the growth, could only have taken place at the expense of the tissue of the tumor itself, unless, perhaps, it was due to the subsidence of an accompanying inflammation.

Some Thoughts Suggested by the Statistics of the Health Department, Especially Concerning Typhoid Fever and Smallpox.—Dr GEORGE L. PEABODY read this paper. (See page 905.)

Dr. ABBE said that many of the deaths attributed to malaria were possibly cases of pyæmia in which the source of the infection had not been recognized. In certain cases of appendicitis, mastoid disease or empyæmia, the condition was often difficult to recognize, and the symptoms—repeated chills, daily elevation of temperature, etc.—were strikingly like those of malaria. The large number of deaths from strangulated hernia was not surprising on account of the delay that so often occurred before these patients were brought to the surgeon. Many general practitioners failed to appreciate the danger of allowing a strangulated hernia to go over twenty-four hours.

Dr. FRANCIS P. KINNICUTT said he was inclined to agree with much that Dr. Peabody had said in his interesting analysis of the statistics of the Health Department. At the Presbyterian Hospital it was the routine practice to inquire carefully into every case of typhoid fever as to the possible source of infection, and in the great majority of cases it was found that the drinking water was the only common factor. It was interesting to note that a large proportion of the patients used neither raw milk nor oysters. The speaker said that accepting the Health Department's statistics as correct, viz., that there was a constant greater prevalence of typhoid fever in the Borough of New York than in Brooklyn, he thought Dr. Peabody's suggestion that this was due to the fact that New York was largely supplied by surface water, while the Brooklyn supply found an efficient natural filter in the sandy soil of Long Island, was a reasonable explanation. Dr. Kinnicutt said he was disposed to agree with Dr. Abbe that many deaths from so-called malaria were really cases of pyæmia. In regard to the removal and segregation of smallpox patients, the speaker inquired whether, under exceptional circumstances, such cases were not allowed to remain in their own homes under the supervision of the Health Department.

Dr. HERMANN M. BIGGS said the figures quoted by Dr. Peabody furnished another illustration of the fact that one was often misled by unexplained statistics. According to the figures, Brooklyn had a higher death rate from typhoid fever than the Borough of Manhattan, although the number of cases of the disease in Brooklyn, according to the population, was less than in New York. This was due to the fact that many of the cases in Brooklyn had not been reported to the Board of Health. The same difficulty in getting cases of typhoid fever properly reported was formerly encountered in Manhattan; less than ten years ago not one-half and probably not even one-quarter of the cases of typhoid fever in this city were reported. Two years ago the Health Department began following up the hospitals in this connection, and it was found that only one hospital, the Presbyterian, was making fairly accurate reports of its cases of typhoid fever. In the others, both large and small, hardly more than one-half the cases were reported. Vigorous steps were at once taken to remedy this. The superintendents of several of the hospitals were summoned before the Board of Health, and since then the proper reports have been forthcoming. The previous defects were due to negligence, as the internes in these institutions are frequently changed, and no one felt himself particularly charged with the duty of making the reports to the Health Department. The same fault was found with general practitioners, and many of the cases treated in private practice were only discovered by the death returns. In such a case, the physician was communicated with, and informed that his neglect to report the case was a violation of the sanitary code. To such a communication, usually, a prompt reply is received, stating that the neglect to report it had been due to an oversight, or that the report had been sent and evidently miscarried, or some other excuse was given, which, if it was plausible and the offence was not repeated, was accepted by the department and the matter was allowed to drop. If no response was received to the first communication, however, a second one was sent, and perhaps a third. Then the matter was referred to the secretary of the board, and a further communication sent to the delinquent. If no response was received to this the matter was turned over to the Corporation Counsel for prosecution. This was the usual routine followed by the Board of Health in the cases of failure to report typhoid fever, tuberculosis and the various other contagious or communicable diseases. During the past three months forty or fifty physicians who had been negligent in this respect had been brought before the Board. On account of this activity, the number of cases of typhoid fever reported in Manhattan had largely increased during the past few years, especially since the

stablishment of the bacteriological department in connection with the Board of Health. An attempt was being made to bring the department up to the same standard of efficiency in the Borough of Brooklyn, but thus far with only partial success. Not only were the returns of contagious diseases from that Borough much more incomplete than those from Manhattan, but all attempts to introduce improved sanitary procedures there had met with a great deal of obstruction. For example, in the adoption and general use of antitoxin in diphtheria it took a much longer time to accomplish in Brooklyn what had been done in two years in Manhattan. The same was true in regard to the prevention and treatment of diarrhœal diseases in children. On account of the comparatively few tenement houses in Brooklyn and the lack of overcrowding and excessive poverty, the mortality of diarrhœal diseases in children in that city should be much lower than in Manhattan, while, as a matter of fact, it had been continuously from 30 to 35 per cent. higher. These figures showed that either Brooklyn people did not boil their milk in summer, or else the children were brought up largely on artificial food or condensed milk.

Dr. Biggs said that during the past five or six years the Health Department had investigated all the cases of typhoid fever occurring outside of the hospitals, and many of them in the hospitals, in order to determine, if possible, the source of infection. In the majority of instances it was of course only possible to learn the probable source of infection, while in isolated cases the true source of infection could often only be conjectured. In every instance, the family or physician of the patient, or both, was visited by the inspector, and special inquiry was made as to whether the patient had been outside of New York during the month previous to the onset of his illness; if so, where he had been, and for how long a time. Inquiry was also made as to whether he was a milk drinker habitually, and whether he had been in contact with any other case of typhoid fever. Also, whether he was accustomed to partake largely of shell-fish, or had recently bathed in either the East or North River. The Department had a regular blank prepared on which these questions were asked, and the tabulation of the information obtained showed in a general way that in about 25 per cent. of all the cases occurring in the Borough of Manhattan, the source of the infection was almost certainly outside of the city, while in a considerably larger per cent. there was a possibility that the disease was acquired outside of the city. About 6 or 7 per cent. were certainly instances of contact infection, while in a considerable number of cases the infection was traced to milk. One group of forty-nine cases was due to milk infection and traced to the same milk supply. This was one of the most difficult sources of infection to trace, as the milk of New York came from a radius of 500 miles and was collected in the creameries from so many different farms that its identity was lost. A certain family, for example, might receive milk one day from a certain group of farms, and the next day from a different group, so that the difficulties of tracing the milk supply of a given family became almost insuperable.

The total number of cases of typhoid fever comprised in small groups was considerable. In a group of ten cases seen at St. Vincent's Hospital, the patients were all employed as stewards on the steamship *New York*. A careful inquiry was instituted as to the source of the infection in these cases, but nothing could be learned until a number of the patients were about to be discharged, when one of the men, who had been desperately ill and almost constantly delirious up to that time made the statement that previous to their illness, the steamship *New York* had been ordered to the Cramp's ship-yards, in Philadelphia, for repairs, and that while there they had been dependent on the Schuylkill River for their water supply. Orders were issued by the chief steward to see that all the drinking water was boiled, but this order was disregarded in the second cabin, and ten cases of typhoid fever resulted. Similar groups of cases had been treated in other hospitals in the city.

Dr. Biggs said he had no doubt personally that a percentage of cases of typhoid fever in New York City, apart from those contracted outside of the city, was the result of milk infection. In from 40 to 50 per cent. of those who apparently contracted the disease in the city, the patients were habitual milk drinkers, which was a very large percentage, compared to the number of habitual milk drinkers as a whole.

Speaking of the water supply of New York, Dr. Biggs said he did not think the facts justified Dr. Peabody's interpretations. The Croton Watershed covered an enormous area, and was very sparsely populated. With the exception of one or two small reservations, the city had acquired title to the land adjoining all the reservoirs and along the banks of the principal streams, and had cleared these of all kinds of habitations and nuisances. There were still a few localities where considerable contamination of the water might take place, but the danger had been reduced to a minimum. Last summer one of the assistant bacteriologists of the Health Department had been in constant communication with the physicians practising on the Croton Watershed, some forty in number, and he was kept informed of all cases of typhoid fever and diarrhœal troubles that came under their observation. Typhoid fever was comparatively rare in that locality, not more than six or eight cases being recorded during the entire summer. Diarrhœal troubles, however, were exceedingly prevalent in some seasons. Not a single instance was found in which by any possibility the water supply could have become contaminated by the evacuations of these patients. Even admitting the possibility of an occasional pollution from a single case, the quantity of the water was so great that the enormous dilution rendered the danger of infection in the city very slight.

Shell-fish, as a possible source of infection in typhoid fever, had received considerable attention from the Health Department, but in these cases the infection was even more difficult to trace than with milk. There were many cases, however, in which the presumption was very strong that the infection was due to shell-fish, and investigation had shown that many oyster-beds were located where the the water could not fail to be polluted by sewage. Some of the oysters were placed in brackish water near the outlet of small streams along the Staten Island, New Jersey, and Connecticut shores, and these streams served as sewage-carriers from the surrounding houses and villages. Dr. Biggs said he had seen a number of cases of typhoid fever in which he thought there could be no question that the infection was due to oysters. Experiments had shown that the typhoid bacilli might be present in the oyster for perhaps twenty-four to thirty-six hours after its removal from an infected water, and that in oysters which were not absolutely healthy the typhoid bacilli were often present in enormous numbers and remained for several days. The Board of Health had at present under consideration certain measures for the regulation of the oyster traffic. In the course of their investigations, one oyster-bed was found at the Erie Basin, the water of which was nothing more than dilute sewage. While the New York Croton water supply was often muddy and had a disagreeable odor, the speaker said he did not think it was a factor of any importance in the production of typhoid fever in New York City. In Brooklyn, however, the drinking water was not above suspicion. Originally, Brooklyn had an excellent water supply, but at the present time, possible sources of pollution had been discovered in Ridgewood and all the way down the South shore. There were a large number of definite sources of possible infection, which had been located, but which the Board of Health was not yet empowered to remove.

Dr. Kinnicutt said that in the purification of drinking water, sedimentation was quite as important as dilution,

if not more so. While the water supply of New York City had the benefit of the latter, it did not have proportionately the benefit of sedimentation. The sedimentation noted in a glass of drinking water or bath indicated how largely the Croton water was a surface water. It was a well-known fact that in a running stream the typhoid bacilli were capable of doing harm after being carried for a long distance in great dilution. Outbreaks of typhoid fever had been reported from the use of water many miles away from the source of infection. As a possible example of this the question was now being agitated in St. Louis, whether the water supply of that city was not being contaminated by the drainage of Chicago. If that be so, the infection must travel through the Chicago Canal and the Illinois River into the Mississippi River.

Dr. Kinnicutt said that all the sources of infection in New York other than the water supply mentioned by Dr. Biggs should necessarily also apply to Brooklyn.

Dr. Biggs said that in the New York City water supply the dilution was on a vast scale, and there was also a certain degree of sedimentation in the several reservoirs connected with the system. Nearly 300,000,000 gallons of water were used daily, and the only possible infection could come from some individual case which might escape detection.

In regard to malarial fever, Dr. Biggs said he quite agreed with Dr. Peabody that the deaths reported from that cause were far in excess of the actual number. The reports in that respect, however, were far more accurate now than they were five years ago, the number of reported deaths from malaria having fallen to one-third or one-quarter of what they were at that time. During the past three years, every death attributed to malaria, coming under the notice of the speaker, had been investigated by a medical inspector of the Health Department, and in every instance in which the facts justified action, the death certificate was changed. In this way, the number of deaths had been cut down to twenty-seven per annum in Manhattan, whereas not many years ago over 300 deaths here ascribed to typhomalarial fever and intermittent fever. In a certain number of these cases, the true cause of death could not be ascertained. A certain number of them were n young infants, with high temperature and sudden death, and the attending physician, without further justification, pronounced the cases malarial fever. A few deaths from malaria had undoubtedly occurred in the Borough of the Bronx, usually in young children.

Dr. Biggs said that the high death rate from diphtheria was largely due to the fact that it was almost impossible to get the tenement-house population to realize the importance of early diagnosis and treatment in this disease. While the death rate from diphtheria in the city, as a whole, was 11 per cent., that among the cases treated by the Health Department inspectors was only 6 per cent. The reason for this was that the physicians in the tenement-house districts did not resort to the use of antitoxin early enough in the course of the disease.

The decrease in the smallpox mortality was undoubtedly due to the very extensive vaccination that had been carried out during the past few years. During 1902 more than 800,000 vaccinations were made by the Health Department, and in 1903 nearly 600,000. As a result of this, smallpox had practically been stamped out. In the few cases that were seen, the infection as a rule occurred outside of the city. No exception was made to the rule that smallpox patients must be removed to the Smallpox Pavilion on North Brother Island, but plans were being made to provide special accommodation for patients who wished to be accompanied by their private physician or nurse.

In reply to a question as to whether there was a law under which smallpox patients could be forcibly removed from their homes, Dr. Biggs replied that the Health Department had absolute power to establish any rule with regard to the protection of the public health, and it was under that provision that the power of removal was exercised. A year ago a smallpox patient in Queens County refused to go to the hospital on North Brother Island. He was forcibly removed and his friends took the matter to the courts. A *habeas corpus* was issued, but no one could be induced to serve it.

Dr. Edward G. Janeway said that while the city water was sometimes so muddy that it was unfit even for bathing purposes, he did not think it could be held responsible to any extent for typhoid fever. Otherwise, that disease would be of more frequent occurrence in the city than was the case. The city was supplied from two sources—one, a high pressure service, which came direct from the Croton Water-shed, and the other through the reservoir in Central Park. In the high pressure service there was no sedimentation, whereas in the reservoirs, which supplied, the lower part of the city, there was more or less sedimentation. The speaker said he favored a filtration plant, such as Philadelphia was now using for the Schuylkill River water.

As another possible source of infection in typhoid fever, Dr. Janeway mentioned the green vegetables that were eaten raw, especially watercress which was usually grown in marshy lands and along the banks of brooks. He had seen a certain number of cases in which this was the only source of infection he could find. Raw fruit was another possible source of infection. He also recalled a case of typhoid fever in a pedler, who had been sick for ten days, traveling from house to house and using the water-closets promiscuously many times daily. He was strongly convinced that raw oysters were the source of infection in certain cases, while among the poorer classes milk was probably a very potent factor.

In regard to the forcible removal of smallpox patients, Dr. Janeway said that was rather a difficult question to handle. If some patients were left at home, while others were removed, it might be regarded as class legislation and the public might object against such discrimination, yet this existed in the dealing with diphtheria and with scarlet fever. The rules in this respect were more stringent than was formerly the case.

Dr. Beverley Robinson said that as long as the Health Department exercised its arbitrary right to remove smallpox patients, every citizen should also exercise his authority and refuse to harbor any person in his house who was not willing to be vaccinated; or, better still, that a compulsory vaccination law should be passed.

Dr. Janeway said he was afraid that a compulsory vaccination law would only have the effect of exciting greater opposition to vaccination than now existed. That had been the result of such a law in England.

Dr. Biggs said that while vaccination was not compulsory in New York, it was practically universal, especially among the lower classes. So far as the public schools were concerned, it was compulsory, and in the large department stores, hotels, and factories it was practically so. At certain periods, or when there was any danger of smallpox, the proprietors of these establishments were communicated with, and informed that the Board of Health would like to vaccinate their employes. Usually, they readily consented. If they refused, they were informed that in case smallpox appeared among their employees, their establishment would be quarantined for such a length of time as the Health Department thought necessary. Such a letter usually brought a satisfactory response. Many of the large department stores refused to engage unvaccinated help. A new difficulty that the Board of Health had to contend with in this connection had recently come to light. Certain physicians and dispensaries on the lower East side of the city had been found issuing certificates of vaccination, which read as follows: "Certificate of Vaccination. Within five years of date, children presenting these certificates are entitled

› attend school under the rules of the Health Depart-ent." These certificates were being sold by some hysicians for ten cents each. A warning had been issued y the Board of Health that they would not be accepted i the public schools.

Dr. Biggs said that every precaution was taken to uard against a mistake in the diagnosis of smallpox. he patient was first seen by one of the diagnosticians of he Department, and subsequently he was examined by he resident physician of the hospital. If there was any uestion about the diagnosis, the patient was kept in a eparate, isolated ward until it was cleared up. Every atient brought to the smallpox hospital was immediately accinated. One objection to allowing these patients › remain at their homes was that it would be very diffi-ult to isolate them: the only way would be to place a anitary policeman at the door, and keep him there day nd night. The removal of smallpox patients was rarely bjected to.

Dr. W. GILMAN THOMPSON said he was glad to hear the tatements made by Drs. Biggs and Janeway that Croton ater was not responsible for typhoid fever in New York ity. The speaker said this had been his own opinion or many years, and he had devoted much study to the tiology of the cases he had seen. He knew of a group f nine cases that developed in a single house last year, nd sometimes he had traced the source of infection in oys to the fact that they bathed in the East or North River at the mouth of a sewer. Such cases were certainly ot attributable to the city water supply. If the Croton ater were responsible for typhoid fever to any extent, he fact would undoubtedly soon be recognized, as it had een in Philadelphia. The statistics quoted by Dr. Pea-body showed a general uniformity in the number of cases, nd suggested a variety of sources rather than a casual nfection of the drinking water. The possible sources of infection were quite numerous. Among them were ice and oysters, and raw foodstuffs polluted by flies.

Dr. Thompson asked Dr. Biggs whether the Croton water was not examined periodically for typhoid bacilli? He had heard that this was done, and that the typhoid germs had never been found, so far as he knew.

Dr. Biggs replied that the Croton water was frequently examined, and it had never been found to contain typhoid bacilli. Rarely, the colon bacillus had been found.

Dr. Kinnicutt said it was a very difficult matter to find the typhoid bacilli, even in water that was known to be freely contaminated with them.

Dr. Thompson said that with regard to the removal and segregation of smallpox cases, he was inclined to agree with Dr. Peabody that more discretion should be shown in dealing with special cases. Without present knowledge of the prevention of infection he thought it was possible to quarantine such cases under suitable conditions, when a special room on an upper floor could be set aside for that purpose. Dr. Peabody's paper furnished an excellent illustration of the fallacy of arguing from unexplained Health Board statistics, and Dr. Biggs had in an admir-able way shown just what interpretation should be placed upon the figures furnished by the city Health Department. The speaker said he had no doubt that the health reports of other cities were often unintentionally misleading in the same way.

Dr. Janeway said that a number of years ago there was an outbreak of typhoid fever among the children at the New York Deaf and Dumb Asylum. There were about 70 cases in all, perhaps one-half that number developing into full-fledged typhoid, while the others were abortive attacks. The epidemic was ascribed to defective sewage. The defects were remedied, but a few years later there was a second outbreak, for which no satisfactory cause could be found. Subsequently, there was a third outbreak, and a thorough examination of the building showed that one of the ventilating pipes had rusted out, and apparently gave rise to some suction between the sewage and drink-ing water supply. This defect was corrected, but there was subsequently a fourth outbreak of typhoid fever, and in this epidemic it was noticed that more boys were affected than girls. There was a pump in the boys' yard, and upon examining the water from this, it was found to be chemically pure, but when chloride of lithium was thrown into the hospital sink, traces of the lithium were found in the water from the pump, showing that there was a connection between the two. The handle was removed from the pump, and since then there had been no more epidemics of typhoid fever in that institution. This illustration of the danger of overlooking the true source of disease had been spoken of previously.

Dr. Peabody, in closing the discussion, said that whether the occurrence of typhoid fever in New York at the present time could be attributed to the drinking water or not, there was no doubt of the fact that the water was supplied directly from the surface, without sedimentation or filtration, and that a water supply of that character always carried with it the imminent risk of an epidemic. This surface water was not only obviously dirty, but came from an inhabited district. The various hypotheses that had been advanced to explain the occurrence of typhoid fever in this city were not entirely satisfactory. Many of the typhoid-fever patients he had seen in the hospitals were not habitual milk drinkers; indeed, it was a frequent experience to find in them an invincible repugnance to milk, which seriously complicated the problem of feeding them during the fever; very few of them had indulged in raw oysters, and they had not been outside of the city. In case an epidemic of typhoid fever did occur in this city from the drinking water, it would be likely to be one of such magnitude as to shock even Philadelphia.

CHICAGO MEDICAL SOCIETY.

A clinical meeting was held April 6, 1904, when cases of aneurysm of the aorta were exhibited and reported. Dr. Frank Billings showed a man forty-five years of age, whose family history as regards tuberculosis, malignant disease, and heart disease was negative. The patient had an attack of typhopneumonia which confined him to bed for a period of three months, when he was nine years of age, from which he recovered. At eighteen years of age he had specific urethritis which lasted for three weeks. He denied any other venereal infection. Six years ago patient first felt a sharp pain in the region of the right shoulder, which came on suddenly. He described the pain as severe, beginning in the anterior portion of the chest, about an inch to the right of the right nipple, pass-ing directly backward through the shoulder, and from the shoulder-blade extending downward along the side of the chest, and sometimes across to the opposite shoulder. About a month ago the patient became incapacitated for work and noticed that his voice was failing. At about the same time dyspnœa came on, which was aggravated by exertion. There was paralysis of the left recurrent laryngeal nerve. With these prominent symptoms and other minor signs, a diagnosis was made of aneurysm of the aorta. Dr. Robert H. Babcock showed a man, fifty-three years of age, laborer by occupation, who had been an inmate of the Cook County Hospital for the past seven-teen months. The family history was negative. Personal history revealed gonorrhœa at the age of nineteen. Patient denied syphilis, and did not give a history of any other important disease. The present trouble began a little over two years ago, with weakness and inability to work, associated with difficulty in breathing and pain. Dyspnœa and pain were present only during exertion. Pain was felt in the lateral aspect of both sides of the chest. Present symptoms were chiefly those of dyspnœa and change in voice, which was husky. His cough had taken on a peculiar character. Patient presented all the symptoms of a case of aneurysm of the arch of the aorta, as determined by inspection, palpation, and auscultation. The treatment had been the ordinary routine treatment

of symptoms—rest in bed, light diet, iodide of potassium, etc. Dr. C. A. Elliott presented a man, fifty-four years of age, in whose case a diagnosis of aneurysm was first made two years ago. Patient had the symptoms of this disease, associated with others. A pulsating tumor could be seen about ten centimeters in diameter, which extended from the second rib to the fourth. The apex beat could be seen in the sixth interspace, about an inch to the left of the mammary line. A generalized arteriosclerosis was present, with pulsations of all the superficial arteries. A capillary pulse could be demonstrated. The pulses showed the characteristic water-hammer pulsation. Tracheal tug was present, but not marked. On auscultation there was a harsh, roaring, systolic bruit at the apex, and a systolic murmur to be heard. Over the aortic interspace there was a double to and fro murmur, both systolic and diastolic. Over the tumor a double sound could be heard, both a systolic and diastolic bruit. Over the posterior aspect of the chest, at about the level of the eighth rib on the left side, one could hear distinct murmurs, both disastolic and systolic. Upon auscultation over the lower parts of the chest many râles were to be heard, and over the left side of the heart occasionally a squeaking rub was heard. The patient having been an athlete, the author thought it was reasonable to suppose that the strain to which he had subjected himself was an etiological factor in his case. The size of the tumor was smaller than it had been. Dr. Charles L. Mix exhibited a man, forty-nine years of age, with aneurysm of the aorta. Three months before he presented himself to the Post-Graduate Clinic, the patient was suddenly seized with an attack of severe pain in the left side, which persisted for a while, disappeared, and then recurred. He had had three paroxysms altogether. In addition there was dyspnœa. Patient had had specific disease. In this case the aneurysm was near the heart. There was dilatation of the venules which one sees in cases of adhesive pleurisy, in some cases of mediastinal tumors, pericarditis, and sometimes in emphysema. In this instance they were scattered well around the chest. The other findings on inspection, palpation, and auscultation were pointed out. Dr. George Galloway reported a case of aneurysm of the aorta. Dr. R. B. Preble reported a case of aneurysm because it presented so few symptoms. The patient appeared at his clinic complaining of dyspnœa on exertion and upon reclining, and was suffering from œdema of the eyelids, which was manifest in the morning, and œdema of the feet, which was manifest at night. During the night the œdema of the lower extremities disappeared, while the œdema of the face appeared, and *vice versa*, during the day. Inspection disclosed extreme tortuosity of the brachial vessels, with a high degree of arteriosclerosis, although the patient, a colored man, was only forty-three years of age. The patient denied a syphilitic history. The heart was considerably enlarged; the apex beat was situated an inch and a half to the left of the nipple line, and in about the seventh interspace. It was strong, but quite irregular in its action, and not particularly accelerated. Percussion disclosed an area of distinct dulness behind the sternum. Other features of the case were pointed out at length. Dr. Preble said the case was in no way remarkable from an aneurysmal point of view, but it drew attention to the fact that in many cases aneurysm was merely an accident. In his case it was an incident of a serious generalized disease, in that there were changes in the heart itself, and in the kidney, which were far more important and serious to the patient than the changes in the aorta. The purpose in having these patients presented to the society was to draw renewed attention to the fact that aneurysm of the aorta were not uncommon; that they were extremely common, no two cases being alike, and anyone who thought, in order to make a diagnosis of aneurysm, he must have auscultatory phenomena, coming on early, was mistaken, because many of the most serious cases of aneurysm of the aorta had very little phenomena. Dr. Frank Billings said that in the last few years he had had several cases in which he had made a diagnosis of dilated aorta, and of all those that had come to autopsy, in more than one-half that diagnosis had been verified. Of the cases he had observed, all but one had occurred in elderly people, much older than any of the patients that had been shown, in people in whom one would expect to find atheroma, sclerosis of the vessels, etc. He mentioned the main points that were noted in taking the history of these cases. Dr. Arthur Dean Bevan said he had noted three types of tumors within the chest, as shown by the *x*-ray, and there were one or two points of great value in making the differential diagnosis. In aneurysm the outline was almost always a regular curve; while malignant growths or mediastinal tumors invariably had an infiltrating outline, if primary, as shown by the *x*-ray. Other pathological processes presented an irregular, curved outline. He mentioned a case in which he assisted at an operation in which a positive diagnosis of mediastinal tumor was made by six good clinicians, the possibility of aneurysm of the aorta having been eliminated. The mediastinal space was opened with the intention of removing a tumor; the patient died on the table. Post-mortem examination revealed an aneurysm of the aorta about the size of a fist.

Pneumococcus Endocarditis.—Dr. Frank Billings reported two cases of pneumococcus endocarditis, and exhibited specimens. The first case was a woman, twenty-two years of age, who gave a history of incompetent heart of five years' standing, preceding acute symptoms, which brought her to the hospital. There was no history of rheumatism or anything of that kind as the cause of the heart disease. Patient complained of incompetency of the heart. There were no evidences of pneumonia. Blood cultures were made, and pneumococci found. The woman subsequently died. The diagnosis was made, after finding the pneumococcus, of acute endocarditis of pneumococcus origin, with probably an old mitral stenosis. The specimen showed a funnel-shaped mitral stenosis, with valvulitis. The next case was a boy, eighteen years of age, who gave a history of rheumatism at five and at ten years of age. During the second attack there was shortness of breath. He was admitted to the hospital on February 27 of this year, and died March 31. A history of incompetent heart was elicited, and an illness of an acute character dating back three or four years. The patient had never had a cough sufficient to warrant one in saying that he had pneumonia, or pain about the chest or back, nor had he had a chill. Shortly after admission examination disclosed elevation of temperature, with a rapid, irregular heart, but the temperature at no time during his stay in the hospital was high; 99° to 100° was the usual range, but he believed it exceeded this point once. Examination showed an enormous heart extending far beyond the nipple and to the right, rather high. The apex beat was plainly heard. There was hypertrophy of the heart, with a loud systolic murmur heard at the apex, transmitted to the left. This murmur was heard all over the heart and heard also in the back. There was an accentuation of the second pulmonic tone. There was mitral insufficiency, with dilatation of the heart. Friction sounds were heard at different times over the lung and pleura. Patient had pain when he coughed, with bloody expectoration. A culture of the blood was made, and the pneumococcus found. A diagnosis was then made of acute endocarditis of pneumococcic origin. Patient died. Post-mortem examination revealed a large heart, incompetent mitral valves, with vegetations along the aortic, mitral and tricuspid valves; acute endocarditis on both sides of the heart, associated with hypertrophy and dilatation; infarcts in both lungs, pleurisy in both lungs, and infarcts in the spleen. This was the fifth case of acute endocarditis of pneumococcic origin he had seen in the last three years. He believed the President (Dr. Preble) had collected three or four. A statement was made to him by a Philadelphia physician not long ago to the effect that

ie believed cases of acute endocarditis were more frequently due to the pneumococcus than to any other one germ; that the gonococcus came next, and then pus germs, etc He said he would not care to sustain such a tatement that the pneumococcus was the most frequent ause of endocarditis, or that the gonococcus was the econd cause.

Cincinnati Academy of Medicine.

At a regular meeting of the Academy, April 4, a paper was read by Dr. Alfred Friedlander on "Medical Inspection of Schools." He said in brief: It has been well said that his is the age of the child; the methods of teaching in the chools are becoming more individualized and suited to the hild's needs. It is recognized that impressions, both physical and mental, obtained by the child in school are often asting for good or for evil. The crowding of the children, he bad air and light, the unaccustomed quiet and restraint, together with cramped position and prolonged mental effort, are all sources of danger to each child.

We call this the age of Preventive Medicine, and we see more clearly day by day the importance of school life in the causation and propagation of disease; we should then try to raise the general bodily efficiency of each child by aiding its natural bodily and mental growth, we should protect it by the prompt temporary removal of those who are sources of danger to it by reason of contagious disease. It is well known that the time of greatest frequency for the acute exanthemata is the school year and the segregating of children in the schools doubtless has much to do with this.

The hygiene of schools to-day concerns itself with the construction of the buildings on the one hand, and the direct medical supervision of the school children on the other. It is the latter question which concerns us here.

In 1884 Germany started the closing of schools for certain epidemics, but the daily medical inspection of schools started in Philadelphia in 1889, but was discontinued because of parental objection. Dr. S. H. Durgin, Chairman of the Boston Board of Health, then started it in the Boston schools in 1894, and from March 1, 1894, to March 1, 1896, 6,571 cases of illness were found by the inspectors; 5,818 of these were sent home, many of them suffering from markedly infectious or contagious diseases. The detection of contagious diseases is by no means the only duty of the inspectors, but also the detection of eye disease, nasopharyngeal troubles associated so often with deafness, incipient tuberculosis, with its frequent precursor, in children, severe anæmia, nervous affections and incipient scoliosis; these should all be reported to the parents and treatment advised.

Long before the systematic inspection of schools was thought of, Cohen of Breslau made extensive observations on myopia in the German schools; in 5 village schools he found 1.4 per cent. of the pupils myopic, in 20 elementary city schools there was 6.7 per cent. found, in 2 advanced schools for girls 7.7 per cent., in 2 intermediate schools 10.3 per cent., in 2 technical schools 19.7 per cent., in 2 high schools 26.2 per cent., and in one university 59.5 per cent. The percentage was seen to increase with the increase of the length of school life and with the amount of study required. In Cleveland, in 1899-1900, 30,045 children were examined and 20.7 per cent. had defective vision; in Minneapolis, of 25,696 pupils examined 32 per cent. had imperfect eyes. A majority of these cases would only have been discovered by such a systematic examination, The school hygienist must then seek to relieve eyestrain as far as possible by the proper placing of desks and blackboards for light and by advising the parents to have the defects corrected. About 90 per cent. of cases of deafness originate in nasopharyngeal troubles which begin in childhood and are, to a large extent, preventable. Defective breathing and chronic inflammations of the upper air passages are also susceptible of treatment, and when untreated, expose the child to a greater extent to many contagious diseases.

The number of cases of contagious diseases discovered each year by inspectors is very large. In Chicago, in four months, 1,417 cases of diphtheria, 648 of measles, 1,160 of mumps and 306 of scarlet fever were found, and in New York last year, 510 cases of diphtheria, 45 of scarlet fever, 168 of measles, 673 of varicella and 201 of pertussis were found and excluded from the schools. In New York last year, 25,264 cases of contagious eye diseases and 156,886 cases of pediculosis were found.

In Chicago, New York, and Boston, where the inspectors are at work, the cases of contagious disease are diminishing each year because of their early detection and isolation. It is not the aim of school inspection to make the treatment of disease compulsory, except in the case of contagious disease, and also it will in no way interfere with the family physician. What prevents the general adoption of this system is expense, but this would be very slight; in Boston 49 inspectors received $9,790 for inspecting schools with an enrollment of 95,561 and in Chicago 50 inspectors received $13,000 for schools with 268,561 enrollment. Cincinnati, with a school enrollment of 44,458, should be able to provide 25 inspectors for at most $7,500 a year.

Dr. Boone, in his last report as Superintendent of Public Schools, says that speaking generally, the sanitary condition of the schools is improving, but that even some of the newer buildings are hygienically unsafe and unsatisfactorily heated and few have any ventilation except by natural gravity.

Dr. S. P. Kramer and Dr. Marcus inspected the schools some years ago and their report says that except for the newest buildings the sanitary conditions were exceedingly bad and that some of the buildings are a disgrace to the city. All these conditions cannot be corrected at once, but there is no reason why medical inspection should not be instituted, as it has been in some cities, notably Philadelphia and Milwaukee, which have a lower per capita expenditure than ours (Cincinnati spent in 1901-'02 $25 for each child, Philadelphia $22, Milwaukee $17, Baltimore $16, New York $39, Chicago $31, Boston $41, and Cleveland $38). In a question of this sort the community naturally looks to the medical profession for guidance and advice. As a body we have certainly been remiss in our duty; it is time to take action, collectively and individually, and to work earnestly and conscientiously for the establishment at once of an institution that has everything to recommend it and nothing except slight expense to prevent its adoption. Medical inspection is in vogue in nearly all the large and in many of the smaller cities of this and other countries. Why not in Cincinnati?

Tetany; Its Association with Chronic Affections of the Stomach.—John Bouchier Hayes reports two cases of tetany. The first patient was a woman aged forty years. Her illness began suddenly with vomiting. She was removed to the hospital and was doing fairly well when she took some grapes and soda water. She was seized almost immediately with spasms involving the whole upper and lower extremities. The arms and hands became particularly rigid. This occurred daily and the gastric irritation and vomiting continued unchecked. Exhaustion ended in death. The intense tetanic spasms simulated strychnine poisoning and a rigid opisthotonic condition of the body after death seemed to give the same evidence. Post-mortem analysis, however, showed no sign of poisoning. The second patient was a man thirty-five years old. For some time he had suffered from digestive disturbances when vomiting suddenly set in. Tetany supervened. He recovered from this attack, but about a year later he succumbed to a similar attack. The writer declares that any factor which exhausts or debilitates the constitution is very liable to induce an attack of tetany.—*The Dublin Journal of Medical Science.*

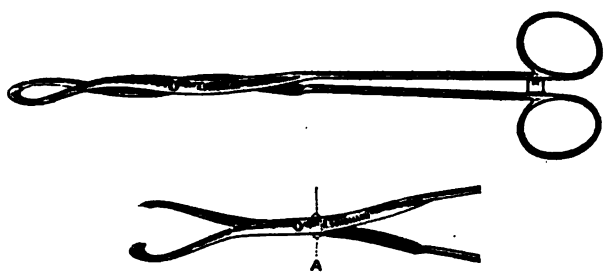
New Instruments.

NEW INSTRUMENT FOR GILLIAM'S SUSPENSION OF THE UTERUS.

By WM. M. GOODWIN, M.D.
NEWARK, N. J.

Dr. D. Tod Gilliam of Columbus, Ohio, has devised an operation for suspension of the uterus which has proven quite successful in his hands as well as in those of Dr. Edward J. Ill, and others. and owing to its simplicity and good results should become the leading operation for retro-displacements.

For the purpose of shortening the time of this operation, and even simplifying its technique, I have devised the instrument shown herewith. It renders the use of silk as a tractor unnecessary; it does not wound or strangle the ligament; it is so constructed that it does not enlarge the punctured wound in the abdominal wall when the forceps is opened to grasp the ligament; it enables one to hold the loop of ligament firmly



in any position necessary for its proper suturing. In cases in which the ligament, in its natural position, cannot be directly grasped by this instrument, the button forceps of Dr. Gilliam, as described in his book, will readily bring the ligament within its grasp.

This instrument was made for me by Reinhold Schumann, Newark, N. J., and is intended to puncture the muscle and peritoneum of the abdominal wall, as described by Dr. Gilliam, then to grasp the round ligament at the proper distance from the uterus, with or without the aid of the button forceps above mentioned, then to draw the ligament up through the punctured wound, when it may be sutured fast to the external fascia of the rectus.

64 Congress Street.

A Note on Primary Ether Anæsthesia for Short Operations—Pleasant, Safe, and Efficient.—Edward J. Brown advocates the use of primary anæsthesia in operations on the throat. He has recently employed this method in the case of 21 different patients, mostly young children. The ether was administered by the drop method with the ordinary chloroform mask, from 8 to 12 grams being used in from 1½ to 2 minutes, and in most cases following one or two applications of 20 per cent. cocaine. In a few of the later cases the cocaine was omitted without apparent disadvantage. The children have all taken the ether without objection, breathing deeply with the mouth open, and at the proper time allowing the instruments to be introduced without the necessity of a mouth-gag. Vomiting attributable to the ether has not occurred, nor has undue hemorrhage. The operations have nearly all been performed in the office. The writer recently made an internal Wilde's incision, in a case of acute mastoiditis in a four-year-old boy. He applied the "cocaine, carbolic acid, and menthol mixture," administered ether for 1½ minutes, and then freely incised the membrana tympani and the posterior-superior wall of the canal. The boy sat quietly and made no outcry, and later said that he had suffered no pain.—*Northwestern Lancet.*

HE ASSOCIATION OF SURGICAL LESIONS IN THE UPPER ABDOMEN.*

BY WILLIAM J. MAYO, A.M., M.D.,
SURGEON TO ST. MARY'S HOSPITAL,
ROCHESTER, MINN.

HE history of medical advance from the empirical eatment of symptoms to scientific expectancy, has en based on the study of death and modern re-arch work. The spirit has been fine, although mewhat pessimistic. The great advances have en along the line of preventive medicine and in e elucidation of problems connected with the eti-ogy of disease.

Surgical progress has been, to a certain extent, rough similar channels; the spirit, however, has en one of magnificent optimism. The great ivances in surgery have come from the clinical side, odern technique having enabled examination of imary conditions during life.

As a groundwork for the study of medicine the athologic laboratory and autopsy room offer unriv-led advantage, but they teach end results only. ho of us has not admired the precision with which trained observer makes a diagnosis? A few days ter one visits the autopsy room and here observes hat this almost clairvoyant analysis was correct. t the same time, we must also acknowledge that he patient has not profited; it means a hundred ages of pathology and two meager lines of treat-ent. How many times do we notice in the autopsy velations that the original lesion has been but ight, and at one stage easily curable, the pathology resent largely the result of secondary complications nd terminal infections?

The post mortem has been an institution for years, et what did we know about appendicitis until sur-ery led the way, or about gallstone disease, supposed o be an "innocent post-mortem finding," until oper-tion opened up the field? Did knowledge of extra-terine gestation come from the autopsy? By no eans. It was through the surgeon's knife, and hy? Because secondary conditions so often mask he original lesion at the post-mortem. On the con-rary, our understanding of acute conditions causing udden death has been brought about by dead-house nvestigations; for instance, fatal hemorrhage and perforation placed acute gastric ulcer on a sound oundation. Not so chronic gastric and duodenal lcers with late death from complications, cholan-eitis from gallstone disease, and chronic pancreatitis rom the same cause. These conditions could not be orrectly studied, excepting after death from acci-dental cause, and real progress lay dormant until surgery invaded the field.

From research work we have profited much; we are gaining rapidly by this means day by day, but we cannot compare the animal to the man, nor can we always artificially create similar conditions. Like the post mortem, it has its limitations, yet these two fundamental methods have enabled us to advance. Without them we would still be in the middle ages. Now the time has arrived, in the light of these investigations, to view conditions from a new standpoint at a time when the lesion is in its infancy, long before the post mortem, while the patient may be benefited and the research work applied to the elucidation of living problems.

The medical man must haunt the operating theater as he has haunted the autopsy room and the laboratory. The times have changed; we must have more treatment and less pathology. It is here that surgery wins its triumphs. We must not forget, however, that to physicians of pathologic training we owe the knowledge which enables us to approach the subject. Courvoisier was the real father of gallstone surgery. It was Balzer, Fitz, Opie, and others who cleared up the pathology of pancreatitis, and surgery followed their lead. It is in the union of the internist and surgeon that progress is most rapidly made, and in the readjustment of science the former will be the architect and the latter the master builder.

Once more the physician and surgeon will come together, and the mistakes of endeavor in new fields will receive timely correction at the hands of the pathologist and experimental worker.

The surgical borderland of to-day lies in the upper region of the abdomen, a locality until recently considered almost purely medical. What are the reasons for this invasion, and have the results justified the attempt?

Surgery must be judged on three grounds: First, the mortality of the operation itself and the question whether this is greater than under the expectant plan; second, the permanence of cure contrasted with medical treatment; third, the question of disability, either introduced by the operation itself or the natural length of time which the healing process involves. On each one of these considerations we must answer yes, and we can go still farther and say that earlier operation would reduce the mortality and increase the permanence of cure and lessen the disability.

Certain parts of the body are so closely related in their anatomy, function, and pathology as to be almost necessarily considered as part of the same system. The generative organs of women form so distinct a field of work as to have built up a specialty. Can we separate diseases of the kidney from the ureter, bladder, and urethra? By no means. Each may stand in an etiologic relationship to the others which cannot be ignored.

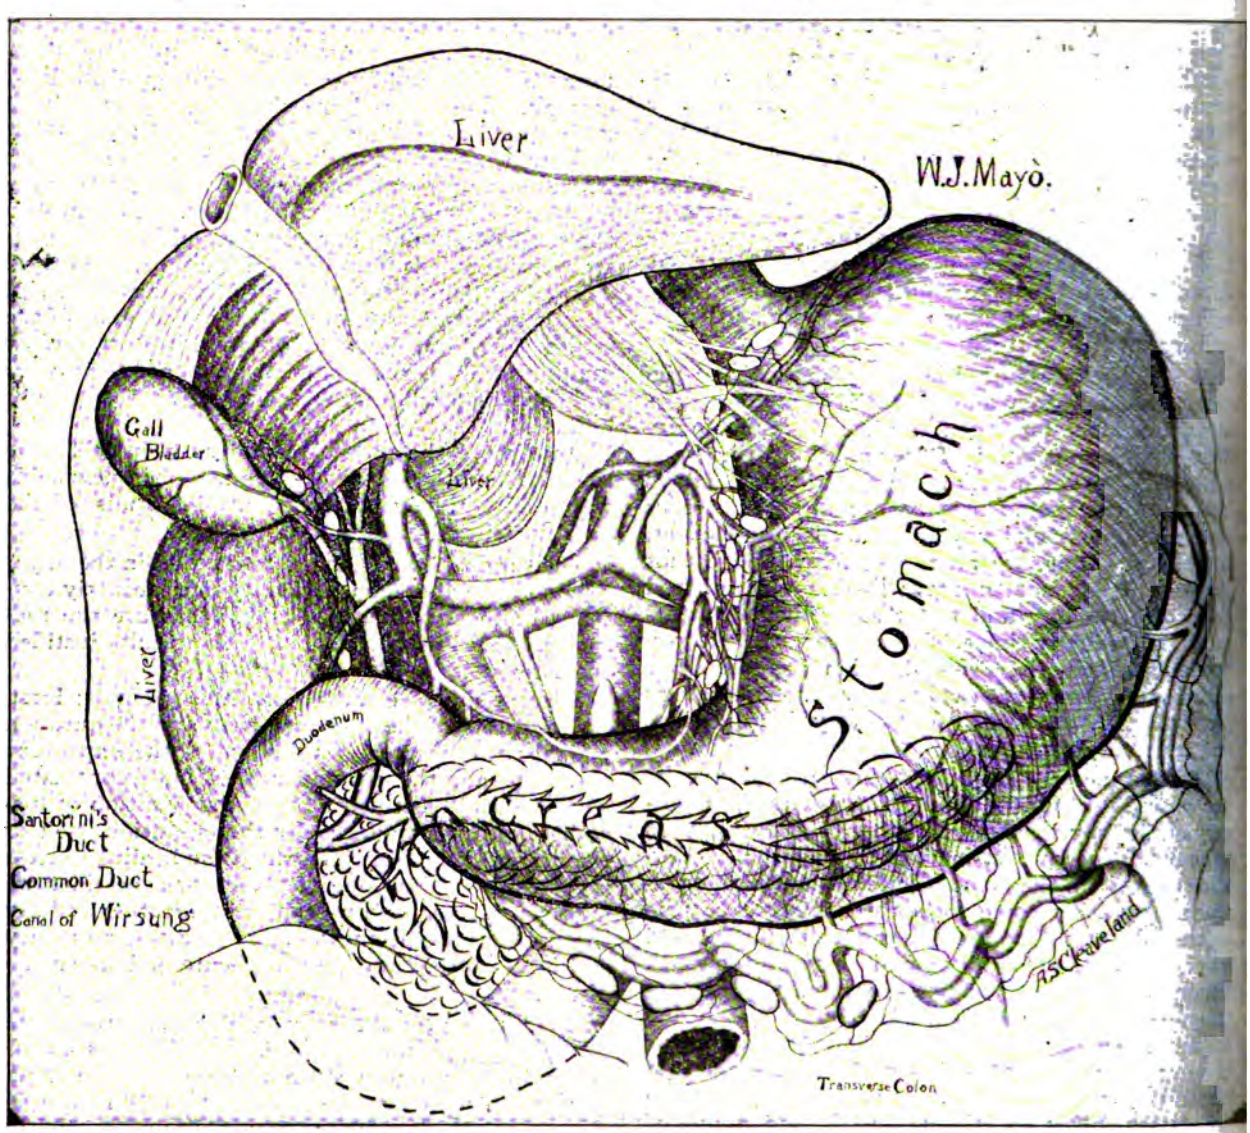
In the upper abdomen we have attempted to study the stomach independent of the associated organs, the liver and bile passages, the duodenum and pancreas. The result has been a confusion in diagnosis and treatment. The palm of a hand may cover a serious lesion of any one of these organs, and that, too, at the point of greatest liability; not only so, but any one of this group may start a pathologic process which may extend to any one of the others, and with fully as great frequency as occurs under similar

*Oration on Surgery at the fifty-fifth annual session of the American Medical Association, at Atlantic City, June 7 to 10, 1904. From advance proofs, through the courtesy of the *Journal of the American Medical Association.*

conditions in either the generative or urinary systems.

Note the disturbance of the stomach which occurs with gallstone disease; the adhesions to the duodenum and the pancreatitis, an association direct as it is vital. Again, let me call attention to chronic ulcer of the stomach with adhesions to the pancreas, secondary ulcer of the duodenum adherent to the bile passages or gall-bladder. These are not fanciful pictures, but drawn from everyday work. I have no hesitation in saying that with an operative experience of over 1,400 cases of this description, mistakes in exact diagnosis are still common, and in many instances unavoidable. The history may be the only valuable diagnostic resource when the patient comes to us, and we all know how unreliable that may be. Given a history of painful attacks which have been exact nature of which must be determined by incision." The patient does not come to us for the purpose of having a certain operation performed, but seeks relief from suffering and disability.

Let me call your attention for a few minutes to the anatomical diagram, showing the nearly vertical position of the stomach with the pylorus in the middle line of the body, and but little elevated above the lowest point of the gastric cavity. It is turned upward and to the right just enough to prevent the weight of the gastric contents bearing directly on the sphincter apparatus. The only portion of the duodenum in which we are interested is the four inches lying between the pylorus and the papilla of the common duct of the liver and pancreas. This may be called the vestibule of the small intestines. Its position subjects it internally to the perils of ulcer



very severe, but which have completely ceased, with tenderness on deep palpation in the epigastrium, and we may have disease of any one of these four organs, and not infrequently an association either direct or indirect of the pathologic process. If we clearly understand the possibilities of error, we are better prepared to meet complications or execute a change of front and operate on one organ when another procedure was planned. In the majority of cases a pathologic diagnosis is possible, and one can say with certainty, "This is gallstone disease," or "This is ulcer of the stomach"; but in a considerable minority a surgical diagnosis is the best that can be made. That is, we can say: "In this locality is a diseased process which requires operative treatment, the

from the acid gastric juices which its thin tunics but inadequately resist. Externally its function is often interfered with by adhesions to the gall-bladder and bile tract, secondary to gallstone disease. This unoffending bit of intestine is so often offended against as to cause it to become the most frequently diseased portion of bowel of the same length. The remaining eight inches of the duodenum is protected by the alkaline secretions of the pancreas and liver. Its fixed position and peculiar horseshoe shape, with its delivery point nearly as high as its origin, enable it to retard mechanically the ingested material during the mixing process for which its large caliber affords accommodation.

The anatomy of the bile tract is equally interest-

ıg, and especially the relations of the common ver duct to the pancreatic duct and the duodenum. here is continuity of mucous surface, each pro- ecting itself from the secretions of the others by the ıechanical washing effects of its own secretion, ıe joint discharge and a feeble sphincter apparatus reventing entrance of the duodenal contents.

The gall-bladder, as it furnished the initial lesion ı more than one-half of the diseases of this group, ; of great interest. Like the appendix, an obsolete rgan of storage function and limited outlet, it ives rise to a variety of troubles, which we are only f late beginning to appreciate. It is an old aphorism iat "Nature finds mischief for idle hands to do." he gall-bladder has a capacity of about an ounce, nd as we find almost universally in organs of torage function, the neck is raised slightly about he lowest point to prevent the weight of contents sting directly against the outlet. The little pouch us formed may be called the pelvis of the gall- ladder (Brewer). It is here that the obstructing tone is so frequently lodged in cystic impactions. Murphy observes that the fundus of all organs as but few lymphatics, while the region of the eck has an abundant supply; hence, even with ptic contents, there is but a mild reaction when he pelvis is obstructed, as compared with the artling temperature curves of duct stones.

The pancreas, composed of two originally separ- ed parts, has in nearly half of the specimens ich have been examined two patent ducts, that Wirsung, which is the important one, uniting the common liver duct. The minor duct of orini, however, has a possibility of useful func- in certain diseased processes, as pointed out Opie. The pancreas was originally an intra- oneal organ, becoming retroperitoneal by a evolution (Huntington), and in this anatomic liarity Brewer believes lies one of the reasons he diffusion of fat necrosis resulting from acute reatitis. Mikulicz has called attention to the that adhesions to the pancreas in gastric cancer e a mortality of 73 per cent. in his resection es. Robson also notes the pancreatic mischief asioned by perforating gastric ulcer on the terior wall.

The blood supply of this group of organs is almost irely from a single source in the celiac axis. It been experimentally developed that the sever- ce of all connections of the pancreas excepting blood supply, does not check secretion if food placed in the gastrointestinal tract. In the ve supply from the pneumogastrics and sym- thetic ganglion, we find the same direct relation- ip involved. If we study the function we see same association. The stomach can be com- red to a mill, the fundus the hopper, in which food is macerated in a weak solution of pepsin d hydrochloric acid, and the muscular pyloric ortion the grindstones in which the masses are oken up into a homogeneous whole. The entrance food into the duodenum causes the outflow of liary and pancreatic secretions, the absorption turning to the liver by way of the portal vein. This is so elementary that you wonder that I should fer to it, yet the causation of the common sur- ical lesions lies in perversion of these fundamental nctions, and is just as simple. Mechanical injury of the pyloric portion and excessive acidity of the astric secretions, under anæmic conditions, give se to ulcer and lie behind the precancerous lesions which Ochsner notes is found in the history of cancer of the stomach in the majority of cases. The acidity of the gastric secretions renders the contents of the stomach, when turned into the intestine, relatively sterile, but increases the liability of ulcer of the duodenum. The sterility of the upper intestinal tract is still further increased by intestinal absorption, as shown by Adami, the bacteria being picked up and destroyed in part by the glands. Many germs are, however, carried to the liver, and here either annihilated or screened out of the blood in the portal vein and discharged with the bile. We must look on the bile as always containing a few bacteria, and it is probably this attenuated infection of bile retained in the gall-bladder which gives rise to gallstone disease, which in turn is the chief factor in the production of duct inflammation of both the liver and pancreas.

These considerations, so briefly outlined, taken in conjunction with the embryologic origin, justify the grouping of *the surgical lesions of the upper digestive tract*, and at once enable the diagnostician to associate the symptoms and the surgeon to direct his attention, not to one, but to the entire group of organs. The burden of proof lies with the practitioner, not only to demonstrate that the disease rests in one organ, but to differentiate and show that no other is involved.

The art of the diagnostician lies in the proper valuation of the signs and symptoms of disease in organs of associated function and pathology. The instinct which seems to lead some men to a correct conclusion, and by a mental process they could not themselves analyze, usually depends on few things, the immaterial or inconclusive evidence being unconsciously discarded. For instance, note the value of the colic in the diagnosis of gallstones. The typical attack comes on and stops abruptly, is relieved by vomiting or a feeling of movement of gas, is irregular in time, in regard to food, and not accompanied by temperature or pulse elevation, and leaves the patient able to attend her duties almost immediately after cessation of pain. While the pain lasts, it is excruciating, felt in its greatest intensity in the epigastrium, radiating upward behind the sternum and into the back. The distress penetrates to the right side, but occasionally to the left, and lasts from a few minutes to six or eight hours. When the patient comes to the physician it may have been years since the typical attacks; he may have forgotten them, the present trouble complained of being pain, digestive disturbance, and tenderness on deep pressure over the gall-bladder region. The history of the early attack is worth more than the physical examination in many cases. Compare it with the pain in gastric or duodenal ulcer, which may be just as severe, but lasts a day or two longer, especially when due to regional peritonitis, and is accompanied by gastric symptoms and local tenderness. The patient diets, which means he reduces his food supply. The symptoms last more or less for some days or weeks, and the interval of apparent cure gives some weeks or months of comparative health.

Acute perforations of the organs of this group are relatively common and give rise to symptoms which would be at once recognized if they occurred in the region of the appendix, but, occurring in the upper abdomen, too often go to a fatal issue unoperated. The initial symptoms are remarkably alike, whether of the gall-bladder, the duodenum, stomach or acute perforation of the pancreas with fat necrosis. The onset is essentially the same in each. Sudden extreme epigastric pain, with collapse, ushers in the attack, and muscular rigidity, as a rule, comes on early. The diagnosis of perforation, if we are on our guard, is easy, although it may be difficult to say which organ is affected; but this does not make any difference. The vital consideration is that it

has happened, and immediate operation must be performed.

In 811 operations on the gall-bladder and bile tract we had 4 acute perforations of the gall-bladder, with but one recovery, although the average mortality in the benign series was but 4.47 per cent. In 45 operations for duodenal ulcer, 4 acute perforations occurred, with 2 recoveries, while in the 41 operations for subacute and chronic ulcer there was only one death. In 469 operations on the stomach, 5 perforations occurred, with 2 deaths. In 32 operations for diseases of the pancreas, there was only one operation for acute pancreatitis and fat necrosis, with recovery. This gives 14 cases of acute perforation, with a mortality of 50 per cent., and why? Because the operation was usually too late. The death rate in over 1,150 operations for subacute and chronic benign conditions of this group of organs averaged a little less than 5 per cent., counting as a death from operation any patient dying in the hospital without regard to cause or time elapsed between the operation and the fatal issue. If we add to this mortality of 50 per cent. in operations for acute perforation, the cases seen in a moribund condition beyond even attempt at relief, and the still larger number in which death occurs without an ante-mortem diagnosis, we get some idea of the appalling nature of the disaster. To be successful, operation must be immediate; the condition is as imperative as hemorrhage from an artery of the third class. Few recover operated on later than ten hours after perforation. The conditions simulating perforation in the upper abdomen, such as thrombosis of the mesenteric or splenic vessels, diaphragmatic and duodenal hernia with strangulation, and so forth, are rare, and likewise call for early operation.

As a rule, the history and location of the early acute pain will furnish evidence as to the origin of the trouble. Preceding perforation of the gall-bladder there are often symptoms of several days' duration with a history of gallstones. The acute pain occurs in the gall-bladder region. Early drainage with removal of the gall-bladder should give a mortality of not to exceed 10 per cent.

Duodenal perforation usually occurs in cases of chronic ulcer with years of symptoms preceding; but the immediate onset is exceedingly acute, and not ushered in by a few days or hours of prodromata, as is often the case with the gall-bladder. The location of the early pain is just to the right of the median line. The liquids gravitate at once to the appendical region and simulate perforated appendix. The rapid diffusion of escaping contents is fatal to delay. Operation for acute perforation of the duodenum is rarely successful after eight hours. Suture of the perforation with suprapubic pelvic drainage, and after-treatment in the sitting posture (exaggerated Fowler's) in early cases should give 80 per cent. or more of recoveries.

Gastric perforations occur on the anterior wall, according to Brunner, 7 times to 1 posterior, and near the cardiac end 5 times to 3 times in the pyloric portion, and near the lesser curvature 122 times to 16 times near the greater curvature. The initial pain is usually to the left of the median line, and early diffusion of fluids is to be expected. Only 10 per cent. occur without previous symptoms of chronic ulcer. The results of operation being in direct ratio to the amount of gastric contents, and the length of time which has elapsed, the treatment is similar to the duodenal ulcer.

The term perforation of the pancreas from inflammation with resulting fat necrosis is a purely pictorial expression, and not a pathologic entity in the sense the word is used in the preceding remarks, yet it conveys the idea and calls attention to the value of peritoneal drainage in its treatment, as shown by Woolsey. The symptoms are sudden pain in the epigastrium, collapse and early extreme distension of the abdomen. On opening the peritoneal cavity, free fluid, often of a hemorrhagic character, is evacuated. The little fatty masses in every direction and the enlarged pancreas call attention to the source of the trouble. This particular phase of acute pancreatitis cannot be separated from the hemorrhagic type in which treatment is as yet in an unsettled state. Those interested in this question will find a mine of information in the Hunterian lectures for 1904 by Mayo Robson.

The group of acute perforations gives an unsatisfactory mortality, with a prolonged period of disability from drainage, and without a certainty of permanent cure of previous underlying conditions. This will not long continue. Like acute gangrenous appendicitis, the condition will be recognized early with corresponding improvement in results.

The diagnosis of the chronic infective lesions of the organs of this group is in a far more satisfactory condition. The general mortality of gallstone operations is not above 5 per cent., taking the cases as they come, but even this is too high. Grouping the cases in which the entire process is limited to the gall-bladder, the mortality is from 1 to 2 per cent., and depends to a large extent on the general condition of the patient. Secondary complications, chiefly those which involve the hepatic and common ducts with resultant cholangeitis, pancreatitis, and so forth, are responsible for the death rate. As practically all of the patients have symptoms on which a diagnosis could be based previous to the complications, it will not be long before early operation in patients otherwise in good health will be the rule as it is now in chronic and relapsing appendicitis. Not only is the mortality thereby reduced but the disability is likewise lessened. The average stay in the hospital for uncomplicated gallstone patients is slightly less than seventeen days; the convalescence of the complicated duct cases is prolonged one or two weeks.

Chronic infections of the pancreas are usually secondary to gallstone disease, and, as a rule, do not occur excepting where the common duct has been directly irritated by the presence of calculi, although the consequences may continue for some time after the passage of the offending body. The results of drainage of the gall-blader and bile ducts are extremely satisfactory. In our series of thirty-two cases there were but two deaths; these patients had coincident suppurative cholangeitis.

Chronic infective lesions of the stomach with ulcer as a type are becoming better understood every day, as surgical operation discloses the actual conditions present. The primary mortality of operations for their relief are in a fairly satisfactory condition, but as to ultimate results we cannot say definitely. For the obstructive complications the result of ulcer, there can be no question as to the relief afforded and at a nominal risk. The dilated stomach with retention or stagnation of food suggests at once drainage operations with gastrojejunostomy as the type. We have patients of this description alive and well more than twelve years after operation.

Chronic ulcer without mechanical obstruction gives a less promising outlook. The very fact that there is normal gastric motility indicates that gastroenterostomy or other drainage operation is less necessary. Our results in operations for this description of lesion have not been wholly satisfactory, and

furnish a considerable percentage of secondary operations and failures to relieve.

Cannon's experiments have shown the same results. A gastroenterostomy on a normal stomach of an animal does not drain the gastric cavity, even if placed at the lowest point. The gravity advantage of the gastroenterostomy is overcome by intra-abdominal tension, and the food, by muscular action, is carried out the pylorus rather than the artificial opening. The magnificent showing of gastroenterostomy in obstruction has led to the indiscriminate performance of the operation in those cases of ulcer in which gastric drainage is normal. This particular phase of the subject must be further investigated.

Chronic ulcer of the duodenum is relatively more common in the upper two inches than in any corresponding portion of the stomach. It is especially liable to perforate, although its sheltered situation usually leads to adhesive protection. Many pyloric ulcers will be found to have their origin on the duodenal side. Gastroenterostomy is the operation of choice, as it diverts the irritating gastric juices and food products from the sensitive surface, thus promoting rapid healing. We have performed gastrojejunostomy 286 times for all purposes, with a mortality of 5½ per cent. in the benign series. The recent improvements in the technique of gastroenterostomy has greatly reduced the mortality and largely eliminated the causes of failure to mechanically relieve the conditions. Moynihan well says that "the surgeon may not unreasonably expect that from being a last resource gastroenterostomy may be considered as a method of treatment worthy of consideration in a much earlier stage of chronic ulcer of the stomach." Excision of gastric and duodenal ulcers would seem to be a wise procedure, but is open to certain strong objections. In 20 per cent. of cases more than one ulcer is present, and one or more may be undetected or lie in an inaccessible situation. It leaves the ulcer tendency unrelieved, and more ulcers may form. Rodman has suggested the removal of the pyloric or ulcer-bearing portion of the stomach with complete closure of both duodenal and stomach ends and independent gastrojejunostomy. We have followed this plan in five cases of inveterate ulcer relapsing after gastroenterostomy, with good results. The gastroduodenostomy of Finney is a most excellent operation, and we would predict a wider field of usefulness than it has enjoyed. We have performed this operation forty-six times, with one death, and no relapse. The theoretical objection is that in open ulcer the food must pass the ulcerated area before reaching the widened pylorus, and obstruction has no part in the production of ulcer, as is shown by the development of duodenal ulcers. Pyloroplasty must be discarded. While we had no death in twenty operations, we had seven relapses.

In briefly calling attention to the malignant diseases of this group of organs, the writer would emphasize the possibilities of cure by means of operation. In the gall-bladder we found 4 per cent. of cases at the operating table had malignant disease, and all of these cases had gallstones present or evidence that they had been present at one time.

Since it has become the practice to remove all thickwalled gall-bladders as useless and a possible source of future trouble, many cases of malignant disease in an early stage have been in this way, as one might say, accidentally cured. We have met with several such instances.

Cancer of the stomach is the most common type of malignant disease in the human body, constituting one-fourth to one-third of the total number. The radical treatment of gastric carcinoma is now on assured ground, with a mortality of 10 per cent., or less in favorable cases, to 20 per cent. in late but still operable disease. The only necessary thing for success is an early diagnosis, and this must be on clinical grounds, supplemented by early exploratory incision. In forty-six gastric resections for pyloric cancer we had seven deaths.

The profession may well look on the surgical achievements in this new field of work with pardonable pride. That there are many shortcomings must be admitted, but in the history of surgery there has never been a territory opened up with equal rapidity, nor one in which the physician and surgeon have worked together in such harmony for the common good. The statistics on which this paper is based represent the operative experience of Dr. Charles H. Mayo and myself.

PROGNOSIS; ITS THEORY AND PRACTICE.*

By GEORGE DOCK, M.D.,
ANN ARBOR, MICH.

THE topic I have ventured to bring before you is "Prognosis; Its Theory and Practice." As a text, let me quote from the oldest work we have on this subject,[1] which, though old, still has the freshness and modernism that genius gives to human productions:

"It appears to me, said the Father of Medicine, a most excellent thing for the physician to cultivate prognosis; for by foreseeing and foretelling, in the presence of the sick, the present, the past and the future, and explaining the omissions which patients have been guilty of, he will be the more readily believed to be acquainted with the circumstances of the sick; so that men will have confidence to entrust themselves to such a physician. And he will manage the cure best who has foreseen what is to happen from the present state of matters. For it is impossible to make all the sick well. This indeed would have been better than to be able to foretell what is going to happen; but since men die, some even before calling the physician, from the violence of the disease, and some die immediately after calling him, having lived perhaps only one day or a little longer, and before the physician could bring his art to counteract the disease; it therefore becomes necessary to know the nature of such affections, how far they are above the powers of the constitution. Thus a man will be the more esteemed to be a good physician, for he will be the better able to treat those aright who can be saved, from having long anticipated everything, and by seeing and announcing beforehand those who will live and those who will die, he will thus escape censure."

In this Hippocrates describes the essential importance of prognosis to the patient and the physician in relation to treatment. Besides this, prognosis is often important to relatives and dependents, not merely for reasons of sentiment, but in order to protect property and prevent unhappiness and destitution that would be as painful for the patient to contemplate as for the others to suffer. There is another aspect not present in the time of Hippocrates —giving the patient an opportunity to prepare himself for the anticipated life beyond the grave. In many cases, too, prognosis may have important bearings on political parties or for the commonwealth.

The patient very often ignores these needs. If he asks for anything, it is usually either the name of the

*Oration in Medicine at the fifty-fifth annual session of the American Medical Association at Atlantic City, June 7 to 10, 1904. From advance proofs, through the courtesy of the *Journal of the American Medical Association*.

disease or that of the medicine the physician intends to use. He really understands as little of the significance of the name as he does of the action of the drug, and is often more quickly satisfied in proportion as both answers are occult.[2] What really should interest him is, as clearly as his mental development permits, some idea of the changes in his body, anatomic and functional, their present seriousness, the chances of death, or of complete or partial recovery, with, in the latter case, the probability of temporary or permanent disability, near or remote, in some organs or functions.

Within the last century prognosis has lost some of its relative importance. Unlike etiology, diagnosis, prophylaxis, and treatment, it has no special literature, and is only occasionally the subject of addresses or essays. But much of the so-called prognosis of the earlier periods was really diagnosis, as in Hippocrates' vivid description of empyema and his remarks in regard to other diseases of the respiratory organs. It also seems a mistake to assume that practical prognosis was more accurate at any period than in later ages of equal enlightment. While we may admit that great masters like Hippocrates himself, Galen, Sydenham, and Boerhaave, were remarkably accurate in their prognostications, there is no reason for thinking that the rank and file, following their rules without having their keenness of observation and precision of reasoning, were more accurate, or as accurate as physicians of a later period when the formal study of prognosis was neglected, but when other means of knowledge were greater than before. We must bear in mind a fundamental difference in methods. The older prognosis was based on the observation of symptoms alone, and consciously or unconsciously took the standpoint of humoral pathology or some equally imperfect theory. One charge against ancient prognosis is not as serious as some have thought, viz., that the prognosis was made without a definite diagnosis. Even now we sometimes have to be satisfied with a very imperfect diagnosis, and yet may make a very good prognosis, at least for the immediate future. But the older prognosis was almost wholly lacking in anatomic, and totally without chemical basis. Realizing how far short of accuracy the diagnosis must have been in many cases, we can understand that prognosis must have failed almost as often. Moreover, in early medicine, most attention was paid to acute diseases, or the acute terminations of chronic diseases, so that the many important chronic diseases that now make so much of medical practice were comparatively neglected.

Whatever shortcomings medicine may have—and those who cultivate the subject most thoroughly feel the needs most deeply—it must be admitted that diagnosis is much more certain than ever before. Not only are we able to distinguish more quickly and more accurately many diseases long known, such as some of the acute fevers, malarial disease, tuberculosis, diphtheria, and pneumonia; but we have learned the existence and the means of detecting many diseases formerly confused with others. As examples, let me name only a few, such as the diseases originating in the vermiform appendix and the gall-bladder, diseases of the pancreas, many diseases of the blood, a large number of diseases of the nervous system and of the ductless glands, and many diseases caused by animal parasites, of which the sleeping sickness is the most striking example at present.

The older prognosis, far from being negligible, is really of fundamental importance. It gives the accumulated experience of ages that, untrammeled by detail, carefully noted broad and elementary features of disease. As gathered together in the aphorisms and prognostics of Hippocrates, and in the numerous commentaries on them—not always improving the original—it furnishes a fund of inestimable value, but like everything else in medical art, this knowledge is less useful when applied mechanically than when worked over in the crucible of personal experience, tested by other methods and transposed into current formulæ.

Older prognosis was possible to collect into fairly circumscribed space, but this is no longer true.[3] In proportion as diagnosis has become subdivided, specialized and enlarged, and as knowledge or morbid processes has become more complex, so prognosis has become more intricate. Older prognosis was based on broad symptomatic lines, qualified in practice, we may be sure, by a consideration of the patient's constitution. The present basis is diagnosis, but of a different kind. It means not merely a recognition of the name of the disease, but a knowledge of the nature of the disease, still incomplete, but rapidly gaining in fulness and accuracy. In many cases we know the causes, and a good deal of the nature of the causes; in many more we know the seats of the disease, and the anatomic, chemical, and functional changes that result directly and indirectly. It is by the study of the altered functions that we can make a prognosis and plan useful treatment without knowing the name of the disease. Clinical and anatomic investigations have been aided by experiments and observations on lower animals, without which our knowledge would have been much less certain than it is. Scores of technical methods have been devised for reactions and explorations; natural forces previously unknown, such as the *x*-rays, have quickly been pressed into service. Long and painstaking observations have thrown much light on complications and sequels, their nature and detection. From all these things the prognosis proceeds naturally in most cases, but here again an indispensable part is a just recognition of the patient's constitution. It is probably true that in this connection we unduly neglect some prognostic aids furnished by the patient, such as changes of the physiognomy. But, on the other hand, we have much more accurate methods of ascertaining the constitutional factor than were formerly available. Constitution is still a somewhat vague term, but we can speak of it here as the result of the functions of all the organs. While the method of representing these functions is still inadequate, we can safely assert that we have much more accurate means of determining the condition of the heart, arteries and veins, and the force of the circulation than we had before; we have gone considerably beyond the recognition of the apoplectic habit in foretelling the danger of vascular disease. We can usually estimate fairly well the efficiency of the blood-forming organs; we can determine with reasonable accuracy the capacity for work of the stomach and intestines, as well as a few details of nutrition and metabolism; we are rapidly getting beyond the limitations of Falstaff's water doctor in fixing the anatomic and functional ability of the kidneys, and we are working toward methods of testing the functions of the liver, muscles, and nerves. When we have all these factors thoroughly investigated it is probable there will be little need of the *vis medicatrix naturæ*, now an essential part of prognosis.

In the conclusion resulting from these things there is no room for a supposititious clairvoyance, an intangible gift of prophecy, a hypothetic intuition that trained intelligence cannot equal or industry surpass. We have a positive foreknowledge, a prescience, a prognosis, corresponding in accuracy and usefulness to our diagnosis, and often in advance of our treatment.

In the foregoing I have spoken of the theory. In

the practical use of prognosis the first to profit by that function is the physician. With an accurate prognosis, based on exact and thorough examinations, knowledge of the natural course of the disease and of the patient, the physician foresees the course of the malady and is prepared for changes, emergencies, and complications. He is thus enabled not only to preserve his imperturbability, so essential in carrying out necessary measures of treatment, but he can also prepare the patient to meet coming events in better physical and mental condition than otherwise, and, what is often of even greater importance, the self-confidence thus shown stimulates the efforts and the compliance of others concerned in the case.

It is not easy to say how much the patient should share this foreknowledge, and how it should be conveyed to him. In many cases the patient does not ask an opinion, and in many others, either because the present disease seems too slight or for other reasons, the physician does not proffer one. Yet it is good mental discipline to work out the prognosis in every case, as a complement to the diagnosis, and in many the results should be stated to the patient. Many things may conspire to make such statements act either favorably or unfavorably on the patient as on the physician.

Physicians, like other people, can often be classified as either optimists or pessimists. Not that these tendencies affect all parts of the individual's activities. One may be a perfect Pangloss in sociologic, political or climatic matters, and yet take a gloomy view of all his patients. (I am not speaking of those who, rarer in the profession than in some of its parasitic growths, habitually exaggerate the danger of their cases, making every angina a diphtheria, every erythema an erysipelas, and every bronchitis a threatened pneumonia). Another who is perpetually cast down by the failure of democratic government or the need of a stronger one, the immorality of the rich and the rule of the bosses, may meet every case with hope and cheer.

But the practice of prognosis should be cultivated as objectively as any other part of medicine. Not only the therapeutic indications suggested by it, but also the human ones, should be carried out without fear or timidity, without unnecessary harshness, but also without the false benevolence that often does more harm than brutal frankness or ignorance. Here, as in other departments of medicine, the welfare of the patient must be the touchstone by which the action proposed should be proved.

No disease should be looked on as insignificant. Nothing seems less becoming than to hear medical men speaking lightly of disease in general, or of any disease in particular. It is no consolation to the mother whose child has died of one of the rare complications of chicken-pox to find that many physicians think that too trivial to concern themselves with it. Nor does it increase confidence in the profession to have hysteria and neurasthenia considered imaginary and ridiculous evidences of perversity, while the impatience, not to say lack of scientific interest, sometimes shown toward other less well-defined neuroses, undoubtedly has some relation with the crowded ranks of followers of isms of all kinds.

In acute diseases the best general rule is still that of Hippocrates (Prognostics; 19, sect. II): "In acute disease it is not quite safe to prognosticate either death or recovery." A case of this kind, however, should not be considered likely to die unless from a complication, or from the effect of a pre-existing disease, though in certain diseases, such as scarlet fever and diphtheria, the danger of a sudden change and of death should be made known in the beginning. Of course, in cholera and plague, and even in cholera infantum, such information is rarely necessary. In some other acute diseases the study of prognosis prepares the physician not to be unduly elated by the remissions that are so reassuring to relatives. The temporary amelioration in meningitis and peritonitis, in which the patient seems almost free from symptoms, may be mentioned. Less disappointing, but still ominous, is the occasional lull in bronchopneumonia. But in the cases I have just mentioned it is rarely advisable to bring the unfavorable probabilities too strongly before the patient. In these we often need the effects of reassurance and of hope. For the latter, as we see it in medical practice, is not merely the "kind nurse of old age—hope—which," as Pindar says, "more than aught else steers the capricious will of mortal man," in acute cases especially it is distinctly stimulating to physical and mental processes. Sir Dyce Duckworth,[4] speaking from a ripe experience, recently gave an address on "Hopefulness in Medicine," in which he emphasized this fact, and Niemeyer, equally successful in his career, at his medical promotion defended among others the thesis *medicus semper hilaris*. On the other hand, it is a serious error not to point out, after recovery from certain acute diseases, the possibility of sequels, sometimes months or years afterward, and the advantage of examinations at intervals for the purpose of detecting them before they become inveterate. The thorough examination of the urine at intervals after scarlet fever, of the lungs, after pleurisy and all bronchitic diseases, of the heart and arteries after many infectious diseases, often has great practical value.

In chronic diseases there are few exceptions to the rule that the patient should be told the nature of his case as fully as possible. At least, in patients who can be made to understand, and who have a possibility of recovery, of definite improvement or of long duration, there are only individual exceptions. Patients with tuberculosis, heart disease, kidney disease, and disease of the alimentary tract cannot get the best possible results unless they understand why and how they should do certain things and why they should avoid others. Tact and patience and a knowledge of human nature are essential in this. The statements made should be as simple as possible, as brief as definiteness permits, without pathologic explanations. Better no statement than an unconsidered or an unintelligible one.

In talks of this kind we too often forget how different are the ideas of non-medical persons, even those who have studied physiology in the public schools, from our own, regarding the body, its functions and diseases. I am always interested in seeing how soon medical students lose the lay point of view, just as one forgets an unused foreign language, and how sometimes they never recover it. Yet unless they do, they lack valuable means of giving aid. Darwin has noticed how everyone who studies profoundly a subject often becomes unaware on what points the ignorant require information. Carlyle, as John Beattie Crozier tells us, imagined his stomach as some old teakettle, thickly encrusted with fur, and I have seen an otherwise intelligent man on the point of using strong sulphuric acid for a cough, because he found by experiment that oil of vitriol dissolved sputum more quickly than any other reagent he had tried. Nor is it enough to make the explanation. We must ascertain whether the statements are understood, and, if possible, whether they are accepted. How often, even with an intelligent individual, after we have stated the exist-

ence of a small tuberculous focus, and described the results of rational treatment, we find the patient shutting himself in a dark and close room, taking "lung cures," cough syrups and more or less medicated cod-liver oil, and how often, after demonstrating the sufficiency of dietetic treatment in a digestive disease, we find the patient taking bitters, digestive ferments, usually well neutralized by alcohol, antiseptics, and other drugs less easy to classify. So time and patience must be devoted to this part of the work, and we should never be discouraged by failure. I am convinced that there is an improvement in the possibility of carrying out rational treatment, notwithstanding the insidious propaganda of useless or dangerous methods in and out of medical journals.

It is much easier to advise in cases that have a strong tendency to recovery than in those that have not, and there is room for difference of opinion and of practice in the latter, because the conditions vary with patients according to individuality and accidental factors. A number of aspects present themselves for consideration. In the first place, there is often an element of diagnostic or prognostic uncertainty, when the prospects are better than they seem. Sir Dyce Duckworth[5] has formulated universal experience in pointing out the advantages of the "cautious 'if,'" and if the alternative accepted is the hopeful one, much good can be accomplished in many cases. An interesting example is given by Kussmaul in his fascinating "Jugenderinnerungen." Having made a reputation as a zealous dissector, and having won over his confiding peasants to the many advantages of post-mortem examinations, he was asked by the father of a girl with advanced tuberculosis of the peritoneum to arrange for an autopsy on the daughter, when she died. Although Kussmaul, too, thought the daughter was lost, he retorted that he could not speak of an autopsy until the patient was dead. Notwithstanding many obstacles, the girl recovered. The tendency to take the less hopeful alternative is still shown in some cases of tuberculous disease in stages not far advanced, though it is not so common, fortunately, as it was not many years ago, to see such patients given over either to a life of dissipation or of abject despair. The prognosis of valvular disease of the heart is also in a much more optimistic vein than it was fifty or even twenty-five years ago. However, in many cases the prognosis needs to be tested by a therapeutic "if" that is not as well recognized as it deserves. The physical conditions may seem hopeless, and yet if the action of the heart can be improved the case may assume a very different aspect. The advantages of trying were well illustrated by a case in which a woman with aortic and mitral insufficiency and moderately severe loss of compensation was given up as beyond treatment by her family physician. Not knowing this I told the relatives the impossibility of complete recovery, the danger of sudden death or more probably rapid failure at any time, but also the possibility of improvement and a fairly comfortable life for some time, all the more worth trying to realize, because the condition was not complicated by medicinal action, and the other important organs showed no serious alteration. The family physician then wrote me admitting that he had stated improvement was out of the question, and treatment not worth trying, although under subsequent treatment the patient lived two years and nine months.

In cases hopeless in a more certain degree than such as I have just mentioned, it too often happens that treatment is abandoned too early in the case. Patients with cancer of the stomach or other inoperable tumors, cirrhosis of the liver, and many other diseases are permitted to drag out their existence without relief. There are several reasons for this. Sometimes families, having been told the truth about such a patient, refuse all further medical aid, even when the conscientious physician who gives the information points out what can still be done.

Many physicians voluntarily discontinue attendance when they realize that the end is inevitable, with the feeling, doubtless, expressed by Sir William Temple. The latter said that "an honest physician is excused for leaving his patient when he finds the disease growing desperate, and can, by his attendance, expect only to receive his fees, without any hopes or appearance of deserving them." This, however, ignores the fact that in such cases the accomplished physician can often do more real good to the patient than in many cases that recover, while the opportunities for obviating despair, alleviating pain and soothing mental anguish, and for exhibiting thoughtfulness, gentleness, persistence, and a variety of resources, are more valuable to the physician than any fee. Even in acute cases it sometimes happens that the physician is either discharged or withdraws because the indications seem hopeless, and I have known of patients with pneumonia living for one or two days in this way, the family waiting for the end of a life that with greater effort might have been saved. Sir Francis Bacon described this tendency as one of the deficiencies of medicine, "so that Sylla and the triumvirs never proscribed so many men to die as physicians do." For, as he continued, "the office of a physician is not only to restore health, but to mitigate pain, and not only when such mitigation may conduce to recovery, but when it may serve to make a fair and easy passage."

Improvement in methods of treatment have an important relation to prognosis, in that many diseases considered hopeless at one stage of knowledge, may in another offer many chances for recovery or alleviation. In this connection a critical knowledge of current medical literature is necessary, and a realization of the value of medical evidence. Few things can be more disastrous to the physician's mental development—never completed—than constant change of therapeutic method, but there are differences. One need not try every drug proposed for the treatment of typhoid fever or pneumonia, nor every new antipyretic or hypnotic. But the physician who does not inform himself quickly of the value of surgical treatment in various disease as it is developed, in pelvic diseases, brain diseases, diseases of the appendix, biliary tract, stomach, and pancreas, comes very near deserving the reputation of an unscrupulous practitioner. In these departments, too, mistakes are made and exaggerations are inevitable concomitants of progress, but the gain is often distinct and unmistakable, and often changes the prognosis from one extreme to the other.

It may seem that I have taken a too purely medical view of the practice of prognosis. Can we always act from the standpoint of simple diagnosis and prognosis, or must we not at times take into consideration the weakness, fears, and prejudices of people? In trying to get the best light on this subject, I have for many years noticed the opinions of patients and their relatives, as well as of non-medical writers, and it is instructive to learn how those who are not physicians approach the subject. Many physicians have been influenced by the views of Percival, from whose interesting work on Medica.

Ethics some of the best parts of the old Code of the Association were taken. Percival said:[8]

"A physician should not be forward to make gloomy prognostications, because they savor of empiricism, by magnifying the importance of his services in the treatment or cure of the disease. But he should not fail, on proper occasions, to give to the friends of the patient timely warning of danger, when it really occurs, and even to the patient himself, if absolutely necessary. This office, however, is so peculiarly alarming, when executed by him, that it ought to be declined whenever it can be assigned to any other person of sufficient judgment and delicacy, for the physician should be the hope and comfort to the sick; that by such cordials to the drooping spirit he may smooth the bed of death, revive expiring life and counteract the depressing influence of those maladies which rob the philosopher of fortitude and the Christian of consolation."

In general, this furnishes a useful guide to conduct, but nevertheless requires some examination. Part of it reminds one of the maxim of John Halle, who, as far back as 1596, wrote:

> Wi h one consent uniformlye
> Comfort the wounded man,
> But unto some good friend of hys
> Express all that you can.

In the first place, the truth is not always so alarming to the patient, painful as it often is to the physician. In fact, it seems to me this is one part of our duties that does not become less trying with increasing experience. To the sick man, whose thoughts have been turned toward the end longer than others suspect, intimation of a fatal end often brings no shock, but rather relief from the ending of a painful uncertainty. According to the rules of the Roman Catholic Church, a timely announcement should always be given, and those who have witnessed the last days of members of this faith can confirm the statement that good often follows, speaking merely from the medical standpoint, and rarely harm, while the same thing is true of many of other faiths or of no faith. Even where we have to give a fatal prognosis there are certain mollifying influences that can be introduced, aside from those that spring from a tender heart. A hope can be expressed based on the fallibility of human knowledge in general and medical knowledge in particular.

The rule in regard to giving the patient a good prognosis and the relatives a bad one, can often be followed, but it is a very fallacious one on the whole. It is often more necessary to keep up the spirits of the relatives, especially those who have to nurse, than those of the patient, so that sometimes the rule can be reversed with advantage. Darwin[9] cites some interesting and instructive examples of this kind, from his father's practice, and Billroth[8] has expressed himself with much feeling in one of his letters. Moreover, the relatives informed, either from a feeling of compassion or otherwise, may not bring the patient to act on the information, and I have known of serious financial loss befalling a family because the relative entrusted with the task of breaking the news to the patient did not do this. Another risk is that the relatives may divulge the fatal prognosis in such a way as to put the physician in the light of a heartless deceiver, and thereby cause the patient to lose all confidence in him. On the whole, in cases in which the patient should know the truth the physician is often the best one to state it, and he should see that this is done before it is too late.

Exceptions to the rule of candor may occur in the case of children, in women with no spiritual obligations or business responsibility, or in exceptional cases of men. No general rule can be laid down, but that such exceptions occur can be confirmed probably by every physician. A striking example of this is quoted by Darwin.[9]

Of course, this part of the subject is closely related to the theory of ethics, and many writers on this subject have touched directly on the question of medical veracity with, as one might anticipate, diametric differences of opinion. Some moralists of the strict school of Kant and Fichte insist that any deviation from the absolute truth is wrong in medicine, as they assert that it would be wrong even for the purpose of saving the whole race. Others believe with Paulssen, who says: "There is not a physician in the world who does not give deceptive answers to his patients, who does not excite hopes that he does not share. He does not blame himself, nor do others, for everyone does the same." Johnson, "the stern old moralist," in his remarks on the subject, laid open a serious flaw in his own logic: "You have no business with consequences, you are to tell the truth." But surely the physician's chief interest is with the consequences, and if he thinks the patient can gain only by misrepresentation, it is just as proper for him to use it as it would be to give a medicine that in other cases might be quite improper. But the physician in such a dilemma would do well to bear in mind the next sentence in Johnson's *ipse dixit:* "You are not sure what effect your telling him that he is in danger may have. It may bring his distemper to a crisis, and that may cure him." Jonathan Dymond, as strict as any one in his morality, threw a gleam of stern humor into the discussion: "Persons frequently employ falsehoods to the sick man who cannot recover, lest it should discompose his mind. This is called kindness, though an earnest preparation for death may be at stake on their speaking the truth. There is a peculiar inconsistence sometimes exhibited on such occasions. The persons who will not discompose a sick man for his interest in futurity, will discompose him without scruple if he has not made his will."

This part of the discussion might be indefinitely prolonged, but I think we can never get far away from the principle I intimated in the beginning—that in practical prognosis we must individualize, just as we have to in therapeutics, with the patient's welfare ever the object of our activity.

Accidents that follow an unfavorable prognosis occasionally suggest a revision of methods. I have already alluded to the error formerly not uncommon in the treatment of tuberculous patients. More acute results sometimes follow a fatal prognosis, as in two of my patients who resorted to suicide. One was a man with far-advanced carcinoma of the stomach, to whom I recommended palliative treatment and advised against a useless effort at radical treatment. The patient left for his home, but threw himself from a fast train and was killed. In another patient, a man with a large kidney tumor, apparently with many adhesions, my surgical colleague and I advised against an operation. The patient went to another hospital, and apparently received similar advice, for he shot himself through the tumor, and died in a short time. From a broad biologic standpoint it does not, of course, make any difference whether an individual organism dies as either one of these, or as it would if left to its fate. But no matter how one may feel on the subject of suicide, I have always thought these men less fortunate than another patient with carcinoma of the stomach, also far advanced. To him, in advising against an operation, I added that if he could find a good surgeon who was willing to operate, he might submit. He underwent the

operation at the hands of one of the most distinguished surgeons in the country, and died on the table. In such a case the result is often unfortunate, because it prevents operations on other and more promising cases, but for the man himself, fighting to the last, it seems to me one can have only respect.

This brings up a question on which a few words may be proper—the question of euthanasia. Every few months some one—usually not a physician—proposes that people with incurable diseases should be killed by some painless method. The plan offers so many opportunities for crime that it would be difficult to carry out, but aside from that it involves important principles. The difficulty of telling when the proper time had come would often be insuperable. Aside from examples of fortitude and other virtues exhibited by the dying, how much the world would have lost if a chronic invalid like Stevenson had the cord of his life snapped at one of the times when the *aes triplex* of his soul seemed battered through! To take a less selfish view, we can think of the "pictures of human patience, the visions of ripened character, which have been revelations and inspirations to generations of mankind" (Phillips Brooks), and see these repeated daily in sick rooms of all degrees, while the self-sacrifice and kindness developed in others at such times cannot but be of untold benefit to the race. To most physicians the suggestion of any planned shortening of life must be abhorrent. For countless generations they have been doing their utmost to lengthen life and lessen disease. They have shown how to prevent the plagues that formerly made life almost as bad as a perpetual illness for the survivors, and they have also shown how many deaths can still be prevented. On the other hand, they can, in most cases, so treat the dying man that the bitter anguish often associated with death is absent, that life is not only less painful but actually longer, so that they will continue to follow the rule of the Father of Medicine, and "give no deadly medicine to any one, even if asked, nor suggest any such counsel."

2. Striking examples of the virtue of mysterious names are conspicuous in the practice of the popular sect of osteopaths. I could give many examples of the license with medical terms among these people, but as the evidence is derived wholly from patients I cite only one that can be vouched for by medical eye-witnesses. A hospital patient with typhoid fever, with the neck pain not infrequently felt in that disease, requested that his osteopathic physician be allowed to treat him. I was not unwilling, especially as the osteopath gave assurances that he would not attempt to treat the typhoid fever. Two internes "assisted" at the treatment. The osteopath, one of the *sang azul* of his class, after feeling the neck, announced that the transverse processes of three cervical vertebræ were displaced on one side. After some manipulation he pronounced the displacement relieved, though I was sorry to see that the pain was not much less than before.

3. I have not attempted to include prognostic details, but would refer those interested to "Observations on Prognosis," by P. H. Pye Smith, Guy's Hospital Reports, Vol. xliv 1887, as one of the most comprehensive and suggestive articles in modern literature.

5. Duckworth, Sir Dyce: "Address on Medicine," *British Medical Journal*, 1896, Vol ii, p. 251.

6. "Medical Ethics; or a Code of Institutes and Precepts," adapted to the professional conduct of physicians and surgeons, with an appendix containing a discourse on hospital duties; also notes and illustrations, by Thomas Percival, M.D., Manchester, 1803. p. 31.

7. "The Life and Letters of Charles Darwin," edited by his son, Francis Darwin, New York, 1887, Vol. I. "Called to see a patient who had been given up to die by the family physician, Dr. Darwin took a different view of the matter and maintained that the man would recover. He was found quite wrong in all respects, and owned his error. He was convinced that he should never again be consulted by this family, and was much surprised at being called in after a few months by the widow. He asked a friend of the widow to find out why he was again consulted. The widow answered that she would never again see the odious old doctor who said from the first that her husband would die, while Dr. Darwin always maintained he would recover. In another case Dr. Darwin told a lady that her sick husband would certainly die. Some months afterward he saw the widow, who was a very sensible woman, and she said, 'You are a very young man, and allow me to advise you always to give, as long as you possibly can, hope to any near relative nursing a patient. You made me despair, and from that moment I lost strength.' 'My father,'" continued Darwin, 'said that he had often since seen the paramount importance for the sake of the patient of keeping up the hope, and with it the strength of the nurse in charge.'"

8. "Briefe von Theodor Billroth, 1902:" Speaking of the slow decline of Professor Breisky, and of the attending physician telling the whole truth to the wife, he remarked: "I admit that under certain circumstances this is necessary: but here I do not think it is necessary. How can the poor wife, without a glimmer of hope, bear the weeks until the liberator of all sorrows gently approaches the husband. We should give her courage, and the poor patient morphine. A hard task. But let us remember that every family physician is in this situation hundreds of times, and often has to see his incurable patients daily. If the young man suspected these mental tortures when he enthusiastically enters the temple of Æsculapius he would surely often turn back. To face the unveiled figure of Sais requires all the undaunted resignation that we slowly win in our profession."

9. *Op. Cit.* "He was sent for by Mr. P., who said 'From all that I have seen and heard of you I believe that you are the sort of man who will speak the truth, and if I ask you will tell me when I am dying. Now I much desire that you should attend me, if you will promise, whatever I may say, always to declare that I am not going to die.'"

PREVENTIVE MEDICINE: ITS ACHIEVEMENTS, SCOPE, AND POSSIBILITIES.*

By HERMANN M. BIGGS, M.D.,
NEW YORK.

GENERAL MEDICAL OFFICER NEW YORK CITY DEPARTMENT OF HEALTH; PROFESSOR OF THERAPEUTICS, AND CLINICAL MEDICINE AND ADJUNCT PROFESSOR OF MEDICINE, UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE, NEW YORK.

THE terms sanitary science, public or State medicine, and preventive medicine, have frequently been used as almost synonymous. The latter term, "preventive medicine," however, has sometimes been restricted in its application to the prevention of the infectious diseases. In the broad sense, preventive medicine comprises both general prophylaxis and individual prophylaxis, and applies to all forms of disease, not simply to the infectious diseases. Preventive medicine is an applied science, which deals with the preservation of the health both of the individual and of the community.

No subject more vitally concerns the welfare of a community than that pertaining to its healthfulness. How the inhabitants live, and how, and at what age they die, what is the extent and character of the morbidity occurring among them and what are its causes, are questions of momentous importance. They are essential features in the problem, whose solution will teach men how they may live longer, healthier, and therefore happier lives.

In rural districts the average healthfulness of the inhabitants depends largely on natural conditions, such as elevation, climate, soil, and, to a much less extent, on the artificial conditions produced by the handiwork of man. In densely popu-

*Address on State Medicine at the fifty-fifth annual session of the American Medical Association, at Atlantic City, June 7-10, 1904. From advance proofs, through the courtesy of the *Journal of the American Medical Association.*

ated cities, on the contrary, the natural conditions become relatively unimportant features in determining the degree of healthfulness, so much do they become subordinated in many cases to the artificial conditions which have resulted from the lives, labor, and occupations of the inhabitants. It may be said with certain limitations that the inhabitants of any city in the temperate zone now have it largely within their power to determine what degree of healthfulness their city shall have. A high morbidity and a high mortality in any urban population depend largely on some remediable features of an insanitary character, such as the sewerage of the city, the occupations, habitations, food, and water supplies, and the habits of the inhabitants—all factors which lie to a great extent within their control. Hence, when any city in modern times has a high annual death rate, for example, 30–35 per 1,000, as was formerly the case in New York, Liverpool, and other cities, instead of a death rate of 17-18, or 19 per 1,000, as now exists in London, Berlin, and New York, it is because conditions are permitted to exist partly from the neglect, indifference and ignorance of the people, and partly from the lack of proper facilities and necessary efficiency on the part of the authorities.

The achievements of scientific medicine have now placed at the disposal of the sanitary authorities such full knowledge as to the causation of so large a proportion of the diseases producing death, and of the means by which they may be restricted or prevented, that the determination of the average death rate is in their hands. This statement is not, of course, intended to mean that it is now possible to prevent or stamp out local epidemics of influenza, pneumonia, cerebrospinal meningitis and some other infectious diseases, but it is intended to cover the average general death rate of a city for a series of years.

The expectation of life at birth in certain manfacturing cities of England has been but little more than one-half that of the healthiest districts of England. Until recent years it was twenty-five or twenty-six years in Liverpool and Manchester, thirty-seven years in London, and forty-six years in Surrey, a healthy country district. Even at the age of thirty, the expectation of life was seven years more for England as a whole than it was for the inhabitants of Manchester. I have estimated that the expectation of life at birth in New York City in 1866 was only a little more than twenty-five years, while in 1903, calculated on the death rate for that year, it had almost doubled, and equaled about forty-two years. For the seven-year period ending in 1873, the death rate under five years in New York City was 123 per 1,000 of the population at these ages. For the year 1903 the death rate under five years was fifty-six. On the present estimated population at these ages, this reduction equals a saving of more than 28,000 lives annually.

These considerations suggest the vast importance of the healthfulness of the community, to the individual at every age, and to the community as a whole, for on this depends not only the relative freedom from illness, but also the probable lifetime of each member.

In the causal consideration of the healthfulness of communities as compared with the conditions existing in earlier times, we are inclined to think without investigation that there has been but little advance in modern times and that while some diseases have been greatly restricted or entirely stamped out, these have been replaced by others equally as fatal to the human race. A little study, however, shows how erroneous are these views. In the seventeenth and eighteenth centuries the average annual death rate throughout the civilized world was at least 50 per 1,000 of the population, and probably it was much more than this. From 1628 to 1635 in London, these years being free from pestilence, the average death rate was 50 per 1,000, and the absolute annual mortality for twenty-four years, from 1620 to 1643, was over 70 per 1,000.

The death rate during 1902 in London was only 17 and a fraction per 1,000. The mean expectation of life in London for the decennial period, 1771–1780, as calculated by Price's table, was 19.6 years, the annual mortality being 51 or 52 per 1,000; while from 1831 to 1835, although an epidemic year is included, the death rate had decreased to about 32 per 1,000. In 1894 the mean expectation of life at birth for all England had more than doubled that of 1780 in London, so that it was nearly forty-one years, and for London alone it was thirty-seven years. From 1771 to 1780 in London not less than five in each thousand of the population died annually of smallpox; in 1810 this mortality had sunk to 2 per 1,000, and in 1835 to 0.8, and in recent years it has been an absolutely insignificant decimal. Fever as a cause of death declined in almost the same ratio, from 6.21 in the decennial period ending in 1780 to 2.64 in 1810, and 1.14 in 1835. In the sixteenth century fever, plague, cholera, and dysentery destroyed annually 31 out of every thousand of the population of London, or nearly twice the total deaths occurring now from all causes. These diseases at the present time, as causes of death, do not equal in London 2 per 1,000 annually of the population.

According to the English life tables up to 1875, 518 out of every thousand children in Liverpool died during the first five years of life; 351 died in London and 205 in the healthy rural districts of England, while in the whole of England 297 out of every thousand died during this period of life. In old New York City (comprising the Boroughs of Manhattan and the Bronx), for the seven-year period ending in 1873, 616 out of every thousand children born died during the first five years of life. As computed by the death rate under 5 in 1903, 280 would have died during these same five years. This mortality, while still far too high, equals a reduction of nearly 60 per cent., and as calculated for the estimated population at these ages, means a saving of about 20,000 lives a year in these boroughs. The death rate in the period over five years of age has naturally shown a much smaller decrease, although it has fallen from nineteen or twenty, as it was in 1865 and 1866, at the time of the organization of the Department of Health of New York City as at present constituted, to about fourteen for the year 1903, being a reduction of nearly one-third. This has been accomplished notwithstanding the fact that the old city has increased during this time from a population of about 750,000 to more than 2,200,000.

It does not seem necessary or desirable for our present purpose to consider in detail the causes of this decrease or the special diseases in which it has taken place, but the facts suffice to indicate the great achievements of preventive medicine during the past four decades. Expressed in human lives, it means in the boroughs of Manhattan and the Bronx a saving of over 30,000 lives a year, and computed at the same rate for the whole city, a saving annually of more than 50,000 lives. I would not be taken as intimating that all of this has been accomplished through the agencies which we usually include under the head of preventive medicine, or that it has been the result solely of the action of the

sanitary authorities. Such an interpretation would be very far from the truth, for many agencies have been at work in the production of these results. But preventive medicine, as I conceive its purposes and scope, should include all of those agencies which are essential and direct factors in the prevention of disease and the preservation of life. These agencies are not necessarily all under the direct control of the sanitary authorities.

In these introductory remarks, and in much that follows, I have taken many illustrations from conditions which exist in New York, because I have been familiar with the sanitary affairs there for many years, and the illustrations which it furnishes serve our purpose as well as if selected from many different States or communities.

It has long seemed to me that the work of the sanitary authorities in this country was too much restricted and the general conception of the scope of their functions was narrow and out of harmony with the spirit and development of modern scientific medicine.

Sanitary work has been pretty well limited along certain old and well-defined lines, much to the detriment of the public health. The medical profession has unconsciously contributed no small part to this condition, because of the existence too often of a certain antagonistic attitude toward the action of the sanitary authorities and the feeling that the occupation of a larger field by them would be detrimental to the best interests of the medical profession. The latter has too often resented and opposed any movement to enlarge the field of preventive work, and has often insisted that its operations should be kept within the traditional narrow lines. Until in very recent years the operations of the health officers have been chiefly confined to the measures adopted for the prevention of the more readily communicable diseases, commonly called contagious. These usually included smallpox, diphtheria, and scarlet fever, and at intervals, yellow fever, cholera, epidemic dysentery, and typhus fever. More recently typhoid fever and measles, and indirectly the diarrhœal diseases of infants, have been generally added to this list. But even in regard to the diseases referred to, the measures adopted have been of an elementary and most unsatisfactory character. It must be admitted, however, that until our knowledge of the causation of many of the infectious diseases was rendered more exact by the discoveries in modern bacteriology, sanitary procedures were of necessity largely empirical, and disinfection was either entirely wanting or the methods employed were quite inefficient.

The scope of the sanitary measures in force with reference to the ordinary infectious diseases has in recent years been greatly broadened. More than ten years ago the Board of Health in New York assumed the position that all facilities and procedures looking to the prevention and cure of the infectious diseases should be afforded by the Department of Health. The establishment of the methods for bacteriologic diagnosis and the facilities for the serum treatment had their origin there, and have since been widely followed.

General prophylaxis, or that portion of preventive medicine which should come directly under the supervision of the health authorities, has or should have, a broader scope than that indicated, and should include the supervision, not only of those diseases which have generally come within sanitary surveillance, but also all the infectious diseases which from their nature are to a greater or lesser extent preventable, in addition to all other forms of disease which are the result of insanitary living, occupations, habitations, or surroundings, including those diseases arising from manufacturing, mining, or other industries which, on account of their nature, are peculiarly or especially injurious to health. It should also include with greatly increased powers and breadth of jurisdiction, the surveillance of the water and food supplies and the sewage disposal.

To return for a moment to the consideration of the infectious diseases to be included in this list, there is a large class of different types of the infectious diseases which are well recognized as being more or less preventable which are not included in the registration returns. These are not dealt with at all by the sanitary authorities, or only to a very limited extent. Mention may be made in this connection not only of tuberculosis in all its forms, whooping-cough, mumps, chicken-pox, and cerebrospinal meningitis, which have been included in the registration returns by some authorities, but have not, as a rule, been dealt with by them, but also of puerperal fever, erysipelas, pneumonia, the diarrhœal diseases of infants, dysentery, malarial fever, influenza, the contagious diseases of the eye, and certain parasitic diseases of the skin, as well as some of the rarer diseases occurring in both animals and man, such as rabies, tetanus, anthrax, and glanders.

The inclusion in the registration returns of such a long list of infectious diseases as has been here indicated requires considerable modifications and expansion of the ordinary sanitary procedures, and such action at first thought is likely to arouse opposition and unfavorable criticism from the medical profession. Such opposition and criticism, however, I believe is without proper justification, and arises from an erroneous conception of the proper scope and functions of the authorities and their relations to the medical profession and the people.

There has long existed a belief in the medical profession, and to a considerable extent it has also been a part of the conception of the sanitary authorities of their functions, that the registration of a case of any kind of infectious disease involved some surveillance of such case by the authorities. The slightest consideration would at once show that with relation to many of the diseases mentioned no such surveillance could be of any real service, and it might be a source of annoyance to the sick person, the family and the attending physician. Much good, however, would result, in my opinion, by such a broadening of the scope of sanitary work, without causing annoyance or being detrimental to any one. I should like, however, to point out that more than a year ago the Board of Health of New York City in the revision of its sanitary code included a number of new sections in relation to the infectious diseases, covering to a large extent the diseases above mentioned. These sections, with the accompanying notes, read as follows:

INFECTIOUS DISEASES.

SEC. 133. It shall be the duty of every physician to report to the Department of Health, in writing, the full name, age, and address of every person suffering from any one of the infectious diseases included in the list appended, with the name of the disease, within twenty-four hours of the time when the case is first seen:

A. *Contagious* (very readily communicable): Measles, rubella (rötheln), scarlet fever, variola (smallpox), varicella (chicken-pox), typhus fever, relapsing fever.

B. *Communicable:* Diphtheria (croup), typhoid fever, Asiatic cholera, tuberculosis (of any organ), plague, tetanus, anthrax, glanders, epidemic cerebrospinal meningitis, leprosy, infectious diseases of the eye (trachoma, suppurative conjunctivitis), puerperal septicæmia, erysipelas, whooping-cough.

C. *Indirectly Communicable* (through an intermediary host): Yellow fever, malarial fever.

NOTE.—In this provisional classification of the infectious diseases, arranged for practical purposes, the most

readily communicable of these diseases, embracing the exanthemata and typhus fever, have been placed in a group by themselves and called contagious. This has been done with a view to emphasizing a distinction, which is not only of scientific significance, but of practical importance, in dealing with the sanitary features of administration. This distinction is furthermore of importance because it avoids the misunderstanding and alarm frequently caused by including in the same class the very readily communicable diseases (such as smallpox), and the much less communicable diseases (such as tuberculosis), which require very different sanitary measures for their control.

SEC. 134. It shall be the duty of the commissioners or managers, or the principal, superintendent or physician, of each and every public institution or dispensary in this city, to report to the Department of Health, in writing, the full name, age and address of any person suffering from any one of the infectious diseases included in the list appended, with the name of the disease, within twenty-four hours of the time when the case is first seen:

A. *Communicable:* Influenza, lobar pneumonia, bronchopneumonia, infectious diseases of the gastrointestinal canal (dysentery, cholera morbus, cholera infantum, summer diarrhœas of infants).

B. *Parasitic Diseases of the Skin:* Scabies, tinea tonsurans, impetigo (contagious), favus.

NOTE.—In this list of diseases reporting is required by the department of health in order that data may be obtained for general and special investigation of the modes and sources of infection and as to the prevalence and distribution of these diseases. The Department of Health does not propose to exercise a sanitary surveillance in these cases, but desires information with a view to the ultimate removal or improvement in the conditions which foster them. Notification is required in certain of these diseases because of the liability to their extension among children in the schools.

It will be noted, first, that two main groups of diseases are specified. In the first group, including the more readily communicable diseases, and some others which are not so regarded, registration is compulsory in all cases coming under the observation either of a private attending physician or an institution. These are separated for convenience under three heads: (*a*) The contagious or very readily communicable; (*b*) the communicable, including diphtheria, typhoid fever, Asiatic cholera, tuberculosis, and a number of others, and (*c*) the indirectly communicable, including only two diseases—yellow fever and malarial fever—which are transmitted solely through an intermediary host. In these three classes compulsory registration is required because in all of the diseases in these classes preventive measures, properly executed, are certainly efficient to a very large extent. As to the propriety of the compulsory registration of all of the diseases included under the first heading, "The contagious or very readily communicable diseases," I assume that there can be no reasonable difference of opinion. Measles, rötheln, scarlet fever, varicella, variola, typhus fever and relapsing fever, certainly without question, should be reported to the sanitary authorities. The necessity for reporting rötheln and varicella rests more in the danger of confusion of these diseases with measles and varioloid, respectively, than because of the importance of the diseases themselves. Our experience in New York has shown again and again that outbreaks of smallpox have resulted from the failure of inexperienced physicians to recognize mild cases, these having been mistaken for varicella and treated as such. Every case of varicella occurring in the city must, therefore, be reported, and all cases occurring in adults are immediately seen by a trained diagnostician. I say all cases of varicella in adults, because experience has shown that very frequently varicella in an adult is a mild case of variola.

In the second class, called simply "the communicable diseases," there might be some question as to the propriety of the reports in some instances. There would be none, however, with regard to diphtheria, typhoid fever, Asiatic cholera, plague, tetanus, anthrax, glanders, and leprosy. All of these diseases are under some conditions communicable and of the greatest importance, yet they are much less communicable than the first class, the contagious.

There cannot now be, nor can I conceive that there ever will be again, any serious question as to the necessity or propriety for the registration and sanitary surveillance of tuberculosis, although this has been a subject of very bitter dispute, and although this disease has come actually under the close supervision of the sanitary authorities in only three of four cities in the United States, and of practically none in Great Britain or on the continent. Pulmonary tuberculosis was included in the list of communicable and reportable diseases by the New York City Board of Health ten years ago, and the measures adopted for its surveillance have been gradually extended, and the lines for its restriction have been drawn closer and closer as each year has passed. Some doubt, however, might properly arise as to the necessity of the inclusion of other forms of tuberculosis than pulmonary tuberculosis in the registration returns, because for the most part these other tuberculous diseases are not communicable, or very slightly so. Bone, joint, intestinal, and gland tuberculosis are practically never sources of infection in other persons, but cases of tuberculosis of the types mentioned indicate the previous exposure to infection of the individual, and they thus point out a probably infected site or family, concerning which the sanitary authorities should have information. Such cases may also disclose unrecognized instances of pulmonary disease. Furthermore, knowledge of all cases is absolutely essential to a comprehensive recognition of the extent and prevalence of the infectious disease, *tuberculosis*. During the past year measures to ensure the registration of tuberculosis in all its forms have been adopted in New York.

The importance of the registration of epidemic cerebrospinal meningitis arises not so much because of the evidence of its communicability as because of the importance of fuller information as to the conditions under which it arises and becomes disseminated. We have in New York City just been passing through an epidemic of this disease, the first serious one for thirty years. During the month ending May 15 more than 300 deaths occurred in New York City from this cause.

The infectious diseases of the eye—trachoma and suppurative conjunctivitis—should be included because of the importance of the adoption of preventive measures in the public schools. Few persons had any conception of the great prevalence of these diseases of the eye in the public schools of New York until after the Department of Health adopted some comprehensive measures for their surveillance. Such a vast number of cases was found that the Board of Health was forced to establish special dispensaries and provide special hospital facilities for their care. Only within a few weeks a second hospital and dispensary has been opened, and in the original one in connection with Gouverneur Hospital an average of about 500 patients a day were treated during the year 1903, and nearly 5,000 cases were operated on for trachoma.

Puerperal septicæmia should be included in the registration returns because modern aseptic midwifery has shown that in most instances this is a strictly preventable disease, and excepting rare cases of difficult or prolonged labor, its occurrence may be regarded as the result of uncleanliness, negligence, or incompetence. The registration and the investigation of these cases by the sanitary authorities should soon result in the exclusion from practice of incompetent midwives, restrict the work

of the criminal abortionist, and foster the practice of aseptic midwifery.

No one, I fancy, would seriously question the propriety of including erysipelas and whooping-cough in the registration returns. So far as this country is concerned, I assume that typhus fever, Asiatic cholera, plague, leprosy, and yellow fever are diseases which will never again call for anything more than occasional or emergency measures for the disposal of isolated cases or small groups of cases. But with reference to one disease in the third class, *i.e.* malarial fever, some remarks may be in point to show the advantages which are likely to result from the interference of the sanitary authorities. We now all believe that malarial fever is not only an infectious disease and indirectly communicable through an intermediary host, but that it is also distinctly preventable.

The registration of cases of malarial fever should be required, not because close surveillance of individual cases is necessary, but because sanitary authorities should know where the sites of infection are, where the breeding places of the anopheles mosquitos are to be found, in order that they may adopt proper means for determining the cause of such areas of infection and the proper measures for their removal. In certain sections of New York City, investigation has shown that in some instances almost every person living within certain small areas has suffered from malarial fever during the spring and summer months of a single season. Such outbreaks are without any question the result of local remediable insanitary conditions, which furnish the breeding places for the mosquitos. But without special information through the registration of malarial fever, knowledge of the presence of much insanitary conditions and their removal may become difficult or impossible. The surveillance in their homes of the individual cases reported is of course not contemplated. That conditions similar to those found in New York exist in other communities, I have no doubt.

Section 134 of the Sanitary Code of New York, covering the second group, deals with infectious diseases of a somewhat different type, and in these the Sanitary Code requires the reporting to the department by public institutions of all cases coming under their observation; but it only requests physicians to report them and does not require such reporting.

Class (*a*) in this group includes some of the more important acute infectious diseases of the upper respiratory tract, namely, influenza, lobar pneumonia and bronchopneumonia, and certain of the more common acute infectious diseases of the gastro-intestinal canal, namely, dysentery, cholera morbus, cholera infantum, and the summer diarrhœas of infants.

The acute diseases of the respiratory tract referred to should, in my opinion, be registered, because they are infectious, because they are of prime importance as causes of death, and in order that general and special investigation may be instituted for the collection of data bearing on the modes of infection and the sources and causes of their prevalence and their distribution. New York City has, during the last winter, experienced the greatest prevalence of these diseases which it has had for many years. In the first four months of the year more than 6,000 deaths occurred from influenza, lobar pneumonia, bronchopneumonia, and acute bronchitis.

I firmly believe that these diseases can be, to a very considerable extent, prevented, but the means and the methods are yet to be determined, and it is hoped that registration will assist in the acquisition of knowledge for the attainment of this end.

A large new field has just been opened by recent observations with regard to the specifically infectious character of many of the cases of summer diarrhœa and dysentery, both of infants and of adults. The results of the investigation of the sanitary authorities in recent years in many large cities have shown in the most conclusive way that these diseases are, to a very large extent, preventable, and it seems probable, or at least possible, from recent investigations, that some forms, at least, are preventable and curable by the use of a specific curative serum.

Investigations in New York and other localities have shown that serious outbreaks of diarrhœa and dysentery have occurred in various institutions and in local areas which were probably, if not certainly, preventable, but concerning which the sanitary authorities have had no information. It seems evident, therefore, that these diseases should be made notifiable. A practical difficulty in this connection exists in the lack of definiteness as to what cases should be included and how the differentiation is to be made between the diarrhœas due to simple digestive disturbances and those of a more serious nature caused by infection. This, however, is a matter for further investigation.

Notification of the parasitic diseases of the skin should be required chiefly because of the liability to the exclusion of these diseases among children in the public schools.

There are certain very large and important questions of prophylaxis connected with the prevalence of typhoid fever and the milk and water supply of our large communities. The occurrence of great outbreaks of typhoid fever, such as the epidemic at Ithaca, N. Y., and Butler, Pa., during the last year, the prevalence in Philadelphia, Pittsburg, and some other cities of the United States and the extensive distribution in the rural districts, constitute a disgrace to American preventive medicine, and should arouse the sanitary authorities, the medical profession, and the people to the provision of efficient measures and the enactment of suitable legislation for its prevention.

The annual cost of typhoid fever in sickness and death throughout the United States would be computed in terms of tens of millions of dollars. All of this loss we know is certainly preventable. If only a small portion of the annual outlay made by the country for sickness and death from this cause were expended in the education of the people as to the cause and the methods of prevention of this disease, and the provision of proper water and sewerage systems, typhoid fever might soon become a rare affection. Unfortunately the city sanitary authorities are often almost powerless in this matter, as their jurisdiction does not extend over the watersheds which supply with water the people under their care, and a supervision by them of the sources of the milk supply is also frequently absolutely impossible.

In New York city detailed investigations of all the cases of typhoid fever occurring within the city limits were instituted several years ago and have been continuously carried on. These show that at least 25 per cent. of the cases occurring in the city have *certainly* received their infection outside of New York City, and a considerable percentage more have *probably* received it outside. Five or 6 per cent. are the result of contact with other cases, and the remainder are in all probability almost wholly the result of infection through milk or oysters. Some more comprehensive measures are urgently demanded to extend the juris-

diction of the authorities in the supervision of the supplies of milk and oysters and other foods.

A serious objection which may be urged against the adoption of the measures here recommended in regard to the registration of many infectious diseases is the increased labor thrown on physicians which their enforcement would involve. The question may properly be asked: Whether the sanitary authorities in the interest of the general public may call on the medical profession for the expenditure of so much time and labor without making any compensation in return. There are thirty-five diseases included in the New York list. The English authorities pay a fee for the notification of each case of infectious disease, and I believe that this course might properly be pursued in this country; but this has not been the custom here, and the authorities generally are not now provided with the funds necessary for this purpose.

When the Department of Health of New York City established its bacteriologic laboratories in 1892, measures were adopted to make some return to physicians for their interest and labor in connection with the sanitary surveillance of the infectious diseases. A systematic plan was then inaugurated, and has since been consistently followed, to secure their coöperation, by offering free bacteriologic examination in the diagnosis and surveillance of various forms of infectious disease. This was first applied to Asiatic cholera in 1892, during the outbreak in New York Harbor, and has since been extended to all of the diseases in which existing scientific knowledge made it possible, cerebrospinal meningitis being the latest disease added to this list. The establishment of this system of free bacteriologic examinations in the diagnosis and surveillance of the infectious diseases, and the provision of facilities throughout the city for the collection of specimens and the sending of reports to physicians, constituted an entirely new departure in sanitary work and has been of the greatest value. The example of New York has been followed by the sanitary authorities in most of the large cities of this country, by many State authorities, and by authorities generally, in Great Britain, and to a certain extent on the continent. These examinations constitute the return which the authorities here have made to physicians for the reporting of cases and for their assistance and coöperation in their care. This return has a very considerable money value, when we remember that for such examinations the usual fee is $5, and as physicians cannot, as a rule, make such examinations themselves, they must work without the assistance thus afforded unless they appeal to the regularly constituted laboratories.

What now are the possibilities of preventive medicine as concerns the larger centers of population? In answering this question we may first take as the basis of our reply the conditions found in some of the large cities with the lowest death rates, or, still better, the conditions found in some healthy rural districts. In considering the crude death rates, as ordinarily reported, however, one must not ignore the influence of the sex and age distribution of the population on the death rate. As is well known, the death rates in the periods of life between five and forty-five years of age are very low, and the death rate among women is lower than among men. If, then, in a city there is a relative excess of the population in the middle periods of life, or an unusual preponderance of women, we may have a crude death rate which seems very low, but which when corrected may be relatively high. For example, the death rate of New York City, as corrected by the English life tables, would probably be at least three points higher than it is. For 1894 the gross rate was 22.76, and the rate corrected by the English tables was 26.46. The corrected death rate of some of the large, rapidly growing Western cities would probably be five or six points higher than the crude death rate reported. The death rate of London at present averages about 17 per 1,000, and when corrected about 18.5 per 1,000, while the Berlin death rate is somewhat lower than this. The crude death rate of Surrey, a healthy rural district in England, is 14 and a fraction, and when corrected would probably be 15.

We can hardly use for a basis of comparison the conditions in any of the cities of this country with very low rates, because the rates have not been corrected, and the basis on which they are calculated cannot always be accepted as correct. Taking all the facts together, and judging of the duration of human life as we know it, we may accept a corrected death rate of 14 or 15 in a large city as a goal toward which preventive medicine should strive and hope to achieve. If we consider the question from another point of view, as to what is possible in the reduction of the death rate from distinctly preventable diseases, we would reach a conclusion not unlike the previous one.

In New York City it may be assumed that the present death rate of 2.7 from tuberculosis may, under proper surveillance, with certainty be reduced to 1.2, and 1.5 points would thus be subtracted from the crude rate. The diphtheria death rate, already reduced 65 per cent. by the use of antitoxic serum, should certainly be reduced to one-third of what it is at present; it is now about .6 per 1,000 population. Similar reductions should be possible in the death rate from typhoid fever, measles, and scarlet fever. The diarrhœal diseases of infants have already been reduced in the last twelve years to one-half of their former prevalence, and should still be reduced more than 50 per cent. Thus more than 3 points may be subtracted from the crude rate in New York, which in 1903 was 18.18. The rate would then be 15+. The rate for 1903 was the lowest in the history of the city.

The most fatal affections with which we have now to deal in New York are the acute respiratory diseases, including influenza, lobar pneumonia, bronchopneumonia, and acute bronchitis. The average death from this group of diseases now exceeds 3 per 1,000 of the population, and in years when there is an epidemic prevalence of these diseases the death rate may be 4 or more, as seems likely to be the case this year.

The advances in preventive medicine have as yet not only had no influence in reducing the death rate from this group of diseases, but, on the contrary, there has been a slow and continuous increase. I cannot at this moment point out the method or the means by which a reduction is to be brought about, but still I firmly believe that with fuller knowledge such a reduction will become possible in the great cities where these diseases are so prevalent.

Something can be accomplished through the closer sanitary surveillance of the occupations and conditions under which the lower classes work, especially the noxious trades. Something, too, may be done through a closer supervision of foods to ensure their purity and freedom from adulteration.

A very difficult problem arises in connection with the diseases of the circulatory apparatus and the kidneys. My investigations have shown that in New York City a large increase has taken place, due to these causes, during the last twenty years. The

acute respiratory diseases, cancer and diseases of the circulatory apparatus and the kidneys are the only important causes of death which have shown an increase during this period. The increase in cancer amounts to about 15 per cent., and the increase in the acute respiratory diseases amounts to about 15 per cent., while the increase in the diseases of the circulatory apparatus and kidneys combined equals about 40 per cent. In making this statement I have taken fully into consideration the possible influence of greater accuracy in the death returns, *i.e.* the inclusion formerly of these under other causes of death; but after making all allowances, it seems to me without question that an increase equaling 40 per cent. has taken place.

A very important sanitary problem is here presented to the health authorities. What are the factors in the lives of the inhabitants of our large cities (for I have found that similar increases, less extensive, however, have taken place in London, Paris, and Berlin) which have caused such a remarkable increase in the prevalence of these affections, and how are these factors to be removed?

The time at our disposal does not permit of more than this elementary and cursory review of the work in preventive medicine. Sufficient facts have, however, been adduced to show how great have been its achievements, and some of the directions have been indicated in which its scope should be extended. With such extensions, and many others not mentioned, for future possibilities of preventive medicine seem to be even greater than the past achievements, for almost every development in bacteriology opens up a new field of work for the sanitary authorities.

5 West Fifty-eighth Street.

EXERCISE IN RELATION TO DIABETES.

By LOUIS BARKAN, M.D.,
San Francisco.

Patient B. L. is of a robust athletic figure and fifty-eight years old. Eight years ago the patient enjoyed full health and was possessed of excellent teeth; shortly afterward when he increased his diet, gingivitis set in and he lost several teeth successively. They were not carious but covered with tartar. A dentist was consulted who declared the gingivitis to be the consequence of "hypernutrition."

The patient's father was of a decidedly gouty disposition and had suffered from a chronic gingivitis for years; his urine was never examined and he died at the age of fifty-eight years of hepatitis suppurativa.

The patient's urine contained sugar occasionally, but he did not heed it much, as his digestion was good, the result of plenty of bodily exercise; the more he worked, the better he felt, and felt best when he resorted to mountain climbing. Sight, hearing, and the other senses were tolerably good, but his memory is weak. He did not drink too freely of fluids nor did he urinate an abnormal quantity.

In the middle of November, 1902, a lipoma of the size of two eggs was removed from his left shoulder, In the first seven days it looked as if the wound would heal by first intention. Loss of a moderate quantity of blood, good weather, a careful diet, and walking three miles every day helped a great deal, but after the seventh day bad weather set in, the patient could not walk much nor be sufficiently outdoors. When on the tenth day the sutures were removed the wound was seen to be in an unsatisfactory condition, which lasted for a fortnight and aroused his fear that the healing of the wound, as is usually the case in diabetes, would be protracted. There was a slight dark colored suppuration, the margins of the wound were sloughing and had to be cut off, and neither cauterization nor other means were of any benefit.

I then changed the diet into a mixed one after I had read the valuable book of Kolish about diet in diabetic patients in which he recommends a mixed and preferably a milk diet, while he considers a rich meat diet only admissible to hard workers.

At the consultations with the surgeon I suggested brisk walking—about eight miles a day—sufficient gymnastics in open air and chopping wood, to which work the patient was accustomed anyhow; the surgeon refused the responsibility for these exercises and so I took it alone. From the very day the patient began to carry out this order, the granulation improved and two weeks later the wound was healed. The good effect of the exercise was quite evident.

Occasionally sugar would appear in the urine, but would, however, disappear when abundant exercise, and especially mountain climbing, was resumed. When on one occasion the patient was excreting much sugar in consequence of a change in diet, the sugar disappeared, in spite of a continuance of the diet after a mountain climbing tour of seventeen miles in one day.

Surgical Treatment of Recent Fracture of the Patella.—Edward Martin and T. T. Thomas summarize their paper as follows: The conservative treatment of fracture of the patella is applicable to blow or tear fractures in which the separation of the fragments is not greater than one-half inch when the knee is flexed to a right angle, and in which there is no great joint tension. Conservative treatment consists in fixation for ten days, the application of adhesive strips to approximate the fragments, the use of elastic bandages to prevent inflammatory exudation, and the employment of massage and passive movements. All fractures of the patella independent of the amount of fragment separation, attended by marked and immediate joint tension, should be treated by the open method. All fractures of the patella in which the fragments are separated more than one-half inch when the knee is bent to a right angle should be treated by the open method, the torn tendinous expansions of the quadriceps being closed by mattress suture, and the patellar fragments being united by silver wire, the insertion of the latter being facilitated by the use of a bone drill with an eye in its boring end.—*Therapeutic Gazette.*

Cataphoresis.—F. O. Marsh concludes that experimental tests tend to substantiate the claim that cataphoresis offers unique and special advantages for the destruction and disinfection of morbid and malignant growths *in situ*, and in many cases reflection would confirm the belief that it offers advantages over the removal *en masse* by the knife, curette, or actual cautery. In any but the most superficial growths it is quicker and more penetrating than the *x*-ray in its therapeutic action. To obtain proper results, the application must be made through the action of the powerful current somewhat prolonged, and used under anæsthesia. The method is, of course, powerless against anything but the local condition when internal metastasis has already taken place. While it is possible to obtain a beautiful primary union after a cutting operation, as an excision of the breast, the ultimate results, as obtained by Massey in over sixty unselected cases of malignant disease, seem to be far superior. A final consideration not to be neglected is the fact that the high mortality from malignant disease, as, for instance, cancer of the female breast, is owing to the difficulty of securing permission to make an early and thorough extirpation. The possibility of obtaining early consent to effective interference without the use of the knife would naturally tend toward a material reduction of the total mortality from malignant disease. —*Cincinnati Lancet-Clinic.*

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

THOMAS L. STEDMAN, A.M., M.D., ASSOCIATE EDITOR.

WM. WOOD & CO., 51, FIFTH AVENUE.

New York, June 18, 1904.

PULMONARY TUBERCULOSIS TREATED BY SERUM MARMOREK.

IN the *Revue de Médecine* for May 10, 1904, Dr. Jacquerod gives, at considerable length and in the necessary detail, his experience with Marmorek's serum, in the treatment of nine cases of pulmonary tuberculosis. In accordance with Marmorek's desire, good cases were not selected, but the cases taken being a number known to have been of long standing and progressive, or at least stationary. The tone of Jacquerod's article throughout is critical, and he makes all the necessary qualifications, in particular remarking that if it has taken ten years to demonstrate the part played in treatment by Koch's lymph, a part that is minimal yet sometimes brilliant, we may expect that it will require much time yet before the value of the present serum can be determined. But his experience with it in his opinion warrants the statement that "we have the impression that up to to-day it is the most important and useful discovery that has been made in this field;" certainly no light praise.

The mode of preparation of the serum has been described by Marmorek in the *Archives Générales de Médecine de Paris* for November 24, 1903. The basis of the serum is the discovery by Marmorek of a new toxin which he believes to be *the* toxin of the bacillus tuberculosis, and the production by injections of this into animals of an antitoxin. As prepared from the horse the serum is pale yellow and perfectly limpid. No antiseptics are added, sterilization being effected by prolonged, moderate heating. The injection is to be made into the subcutaneous tissue of the abdomen; not into the skin or muscles, in order to avoid the local œdema which otherwise sometimes occurs. Marmorek recommends the injection at one dose on the 1st and 2d days, of 5 c.c.; and on the 3d and 4th days, one of 6 c.c.; these injections being followed by a day's intermission, and then by a repetition of the series; the whole cycle ending with 5 c.c. on the 11th and on the 12th days, and then an intermission of 10 days. The cycle is then repeated until a rather marked effect is observed. The physician is then justified in waiting some weeks to see if the effect is maintained by itself. The treatment should be kept up until on such intermission the improvement is maintained by itself for three or four weeks. In acute and febrile cases the dose should be much stronger; from 10 to 20 c.c. Although the author used the treatment with prudence, and indeed with fear, no serious results were at any time observed, and he considers that to-day its harmlessness is demonstrated. The total amount used for any one patient was small. Albuminuria was never seen. Erythema and rheumatoid pains sometimes occur, but are without significance. The first injection never provoked any kind of reaction. Sometimes after the fifth or sixth, a certain amount of general malaise, fatigue, and anorexia, were observed.

In three febrile cases, which had during several months' treatment resisted all the recognized antipyretics, complete and definitive defervescence took place after the injections, and the result could have hardly been attributed to anything but their use. Also in two grave febrile cases with very old lesions and bad general condition, the defervescence was very clearly marked; in one it was incomplete (39.5 to 38.3), while in the other it was complete but transient (six weeks of apyrexia without medication). In one patient who was in general apyretic, but was subject to accessions of fever which yielded with great difficulty to ordinary antipyretics, the fever yielded immediately to one or two small doses (4 c.c.), the effect continuing for a long time. In almost all the febrile cases the temperature during the treatment was some tenths higher, falling one or two days after the last injection. In general, one must not fear to give in febrile cases large doses (10 c.c. for eight or nine days).

Expectoration after the first injection increases very notably, sometimes even to double, to later undergo a progressive diminution to a quantity sensibly less than that existing at the beginning of treatment.

The number of bacilli undergoes only a slight variation, and diminishes only in proportion to the lessening of the expectoration. But in several patients a rather important change in their form was observed. In place of the non-sporulating, short forms with a sharp outline, often after the injections long sporulating bacilli were seen, together with amorphous material such as one finds in chronic foci without a tendency to extension.

The auscultatory phenomena were always favorably influenced. Congestive symptoms, new foci, and increase of râles, were never observed. Even during the preliminary period with increase of expectoration, râles were less abundant, as though evacuation were more rapid and better. In the foci of infiltration with tubular breathing, respiration improved, and sometimes became vesicular.

Under the injections, the general condition always ameliorated, but not strikingly. During the period of administration of the latter, there was never any striking increase in weight, weight being rather maintained with difficulty as appetite existed on sufferance; but after the period of administration was over there was always an increase.

Hæmoptysis was never observed during the treatment. On the contrary, one patient who was subject to frequent attacks, had none for three months following the injections.

The results in three cases of ulcerative laryngitis, were interesting. In one the ulceration healed. The other two showed improvement of the local lesion with disappearance of the painful symptoms and of the laryngeal irritation.

In a word, all the cases treated were improved. On the other hand, none had, up to the date of

writing, been cured. The use of the injections was accompanied by the air and rest treatment.

In concluding, the author says that while the results so far obtained are not perfect, and have often been limited to a symptom, nevertheless the treatment yielded, in a short time, an improvement which he had vainly sought during several months to effect through the use of other means. As the serum acts only upon the toxin generated by the bacillus, and not on the anatomical lesions, it can be understood that the effect must often be only partial. For even supposing the toxin to be completely neutralized and the bacilli reduced to powerlessness, still a cure cannot result from this alone. Constructive work remains to be done to repair the anatomical lesions.

THE MANNER OF LIVING OF THE JAPANESE.

The war in the Far East, and the remarkable successes of the Japanese, both on sea and land, has aroused the most acute interest in this oriental race. Long held beliefs as to the inferior fighting qualities of yellow men to those of white complexion, have received a sudden check, and popular opinions have been somewhat rudely upset. The Japanese have taught Europeans and Americans a lesson and quenched in some degrees the conceit of the Caucasian in his superior capacity to do all things. Even in the matter of diet, our long cherished theory, that the energy and vitality of the white man is largely due to the amount of animal food consumed, must undergo revision. The Japanese are allowed to be among the very strongest people on the earth. They are strong mentally and physically, and yet practically they eat no meat at all. The diet which enables them to develop such hardy frames and such well-balanced, and keen brains, consists almost wholly of rice, steamed or boiled, while the better-to-do add to this Spartan fare, fish, eggs, vegetables, and fruit; for beverages they use weak tea without sugar or milk, and pure water, alcoholic stimulants being but rarely indulged in. Water is imbibed, in what we should consider prodigious quantities—to an Englishman, indeed, the drinking of so much water would be regarded as madness. The average Japanese, individual swallows about a gallon daily, in divided doses.

The Edinburgh Medical Journal, May, makes the water-drinking habit of the Japanese the text for a dissertation on the subject. The writer of the editorial in the Scotch paper thinks that with the British it is too much the habit to avoid drinking water, unless when impelled by thirst—in fact, it is asserted, there are numbers of persons in Great Britain, over whose throats this liquid, in its simple unadulturated form, never passes for weeks at a time. The Japanese recognize the beneficial effect of flushing the system, through the medium of the kidneys, and they also cleanse the exterior of their bodies to an extent undreamt of in Europe or in America. The *Edinburgh Medical Journal*, commenting on the generous use of water by the Japanese, says: "One might have thought that the advantage which accrues to a gouty man, with clogged tissues and muscles, from the copious draughts of water prescribed at any fashionable spa, would have suggested that the same fluid employed at home in modified fashion, might do away with the necessity of a yearly visit to his favorite Kurort. But no, on his return home he resumes his old habits, and eats freely when hungry—or when, according to the time of day, he ought to be hungry—and drinks with meals, but seldom else, unless over his cigar or pipe in the evening, and then not water unblended. Another—and perhaps this is the usage on which the Japanese lay the greatest stress—is that deep, habitual, forcible inhalation of fresh air is an essential for the acquisition of strength, and this method is sedulously practised until it becomes a part of their nature."

The Japanese race is a striking example of the good effects on the body and mind of temperate living. They are a cool calculating people, and have come to an appreciation of the fact, that if their ambition to be a world power is to be consummated, they must be in condition, mentally and physically. to show that they are adapted to such a position. They have proved that a frugal manner of living is consistent with great bodily strength—indeed, is perhaps more so than the meat diet of the white man. As to the water-drinking habit which is so distinctive a custom with them, it is probably an aid to keeping the system free from blood impurities, and might be followed with advantage in European countries, to a far greater extent than is at present the case. Hydropathy and exercise seem to be the sheet-anchors of the Japanese training regimen, and, judging from results, have been eminently satisfactory.

First Report of the German Commission on Tuberculosis.

These researches were initiated for the purpose of investigating the relationship of human to bovine tuberculosis, the raising of this question being due to the pronouncement of Professor Koch at the London Congress on Tuberculosis in 1901. The investigators were Drs. Kossel, Weber, and Heuss, who accept as proven that cattle are highly susceptible to infection with bovine tuberculosis, while remaining insusceptible to human tuberculosis, and that this characteristic is sufficient to indicate the origin of any given strain of bacilli.

The experiments undertaken were exhaustive and painstaking. In the experiments with cattle the summary of the findings was as follows: In cattle, subcutaneous inoculation of pure cultures, obtained from tuberculous cattle or swine, produces almost without execution a general disseminated tuberculosis, which in half the cases kills the animals in from six to eight weeks. (*b*) Experiments with bacilli from fowl tuberculosis showed that they produce a result somewhat similar to that following inoculation with human bacilli. The authors claim that in the experiments made by them with bacilli from human sources in forty-one cases, it is established that in the great majority of cases of tuberculosis in man, bacilli are found which morphologically, culturally, and pathologically can be distinguished from those causing "perlsucht," but that, in exceptional cases, bacilli are found which cannot be so distinguished.

Dr. Theodore Shennan, pathologist, Royal Infirmary, Edinburgh, commenting upon the investigations regarding bacilli from human sources, says: "We may note some interesting points in connection with these forty-one strains of human bacilli and their origin. Six cultures were obtained from cases of acute miliary tuberculosis. In three of these the primary focus was found in the alimentary system. From two out of the six cases the cultures separated caused generalized tuberculosis in cattle. One of these was of ingestive origin; in the other the

channel of invasion could not be accurately determined. Seven cases of primary tuberculosis of the intestine and mesenteric glands were met with. Cultures from the mesenteric glands in two cases produced generalized tuberculosis in cattle. In both cases the "intestinal mucous membrane was free from tuberculous changes. The same was also noted in another case, from which the cultures did not, however, produce a general disease in cattle. Three out of the seven cases were over fifteen years, and all three showed intestinal ulceration, presumably primary. In this connection, one is forcibly reminded of Koch's statement that he had met with only two cases of undoubted primary tuberculosis." The authors are of the belief, judging from their conclusions, that Koch was right when he said that human and bovine bacilli are of different species. Their experiments are not yet finished, and it is possible that when they test the alteration of virulence in a given strain, by passing through a series of animals of the same species, their opinions may undergo a change. Ravenel has shown that the virulence of human bacilli can be so increased in this manner as to approach the pathogenic power of bovine bacilli.

Child Labor.

At the meeting in St. Louis on May 18 of the General Federation of Women's Clubs the subject for discussion was "Child Labor in America." Resolutions were adopted by the Federation protesting against children under sixteen years of age working at night, and advocating the adoption of the "Standard Child Labor Law" in all States having labor legislation. Mr. Homer Folks, former Commissioner of Public Charities in New York City, delivered the principal address. He heartily endorsed the report of the committee in favor of a general effort for the following minimum requirements: First—That no children under sixteen years of age shall be permitted to work at night, that is, between the hours of 7 P. M. and 7 A. M. Second—That no children under sixteen years of age shall be permitted to be regularly employed who cannot read and write simple sentences. Third—That in States in which these two provisions are already enforced we should secure the enactment of the standard child labor law, as outlined by the National Consumers' League.

Mr. Folks, however, pointed out that the battle was only half won when legislation had been secured. Coöperation in the good work must not be expected on the part of industries affected. Enforcement is only possible when adequate machinery is provided. Employers are only influenced by selfish considerations, and so long as they are able to obtain cheap labor, the question of the injury done to the bodies and minds of children by factory labor does not enter into their calculations. Consequently the law will be evaded unless public opinion is shown to be strongly against child labor and the matter is constantly being ventilated by the press. To argue against child labor would be superfluous. It is harmful in the extreme on the face of it, and it is only remarkable that a country in the van of civilization, as the United States is, should have tolerated the system up to now. Most of the European countries have sternly forbidden, by laws which are enforced, the employment of children.

Care of Soldiers' Teeth.

It is widely recognized that in order to be an efficient soldier, teeth must be in good condition. A man with bad teeth cannot masticate food properly and will suffer from dyspepsia and stomach disorders. The military man laboring under disorders of digestion will not be able to fight so well nor to perform his general duties with that zeal and thoroughness characteristic of the individual who is in sound health, qualities very desirable in the soldier. The care of the teeth therefore is now receiving the attention among the civilized nations of the world which its importance deserves. In the January number of the *Deutsche militärärztliche Zeitschrift* the subject is discussed by Staff-Surgeon Richter, a dentist of Chemnitz. Richter states that for military purposes the subjects for discussion are: (1) The extraction of teeth; (2) The filling, and (3) Their replacement by substitutes. The hygiene of the mouth and teeth is described. The teeth should be well cleansed with a brush before going to bed. Cleansing in the morning is less important. If bleeding be caused by the use of the brush, accumulation of tartar is the probable cause. This should be removed by a dentist, if the use of a brush and tooth-pick do not achieve the purpose. Tooth-brush should be soft and straight and the bristles not too closely set. The use of tooth powder and other artificial means of cleansing teeth does not find favor with Richter. Mouth-washes do not destroy microorganisms, and careful mechanical cleansing is far more efficacious than any chemical disinfectant. In order to discover the frequency of dental diseases amongst soldiers, Richter examined 1,000 men of a Saxon regiment in Leipsic. Only 61 had perfectly good teeth; among the others there was an average of 1.4 teeth wanting, and 4.5 decayed. Of the decayed teeth, 2.1 could be filled, while 2.3 required extraction. In one infantry regiment of the German army there were yearly about 2,100 fillings, 2,300 extractions, and 50 sets of artificial teeth supplied.

Hearing in Country School Children.

Dr. König gives, in the *Sammlung swangloser Abhandlungen*, the results of the examination of 787 children in several of the village schools in Germany. The examination was of the most thorough type, comprising in every case, examination with the ear speculum and mirror; of the throat with the aid of the tongue depressor; tests of both nasal cavities for permeability to air, and investigation of the nasal mucous membrane with the speculum and mirror; and, finally, palpation of the nasopharyngeal space in cases which afforded any ground for suspicion of enlarged pharyngeal tonsil. Hearing tests were made with the watch, and with an apparatus described for measuring the hearing as a control to the watch; by whispered and ordinary speech; and by the tuning fork. The results carefully recorded in detail, showed that of the 1,574 ears examined, there was more or less impairment of hearing in 59.09 per cent. (30.44 per cent. for the boys, 28.65 per cent. for the girls). The ages of the pupils ranged from 5 to 14 years. Enlarged pharyngeal tonsil was found in 20 per cent. of pupils at 5 years of age; in 8.43 per cent. of those at 9; the remaining years showing intermediate proportions. More than one-half of the whole number (namely, 561) showed more or less impairment of hearing from chronic catarrh of the tubes. König's conclusions are to the effect that both, in the interest of the children and that of the state, otological examinations of school children are necessary. The best test is that by whispered speech. How much impairment of hearing affects the performance of school children is evidenced by the fact that the lowest place in the class is mostly occupied by those most deficient in this respect. Of those scholars who have on both sides less than one-third of the normal acuteness of hearing, it is in general to be assumed that they are

incapable of satisfactorily following the instruction. It should be the aim of the school physician to see that these cases receive proper treatment, the cost of which should be defrayed in the free schools by the school. The diseases most frequently encountered among the school children are diseases which are capable of being favorably influenced by proper treatment. The rural population is especially disposed to hereditary catarrhal diseases of the auditory apparatus. From the results of the examinations, only about two-fifths had normal acuteness of hearing upon both sides. In about 9 per cent. of the cases the impairment of hearing was brought about by purulent conditions; in about 17 per cent. by enlarged pharyngeal tonsils; and in about 60 per cent. by catarrhal lesions of the Eustachian tube or middle ear. About 15 per cent. of the boys investigated would not be able to do military duty in the standing army. Only 2.5 per cent. of those afflicted were aware of their defect.

Electricity for X-ray Work in the Field.

One of the greatest drawbacks to the use of the *x*-rays during active warfare is the difficulty of having a supply of electricity at hand. Ofttimes the obstacles in the way of diagnosing by means of the *x*-rays in the field are for this reason insurmountable. It has been demonstrated in practice that primary batteries, thermopiles, and static machines are unsuitable for obtaining the necessary supply of electrical energy. Lieut.-Quartermaster F. Bruce, Royal Army Medical Corps, writes in the *Journal of the British Royal Army Medical Corps* for May on the subject. He points out that in a paper of his read before the Röntgen Society, he maintained that for field use no *x*-ray apparatus can be considered complete which does not possess its own means for generating electricity. This opinion is now shared by other experts. Lieutenant Bruce has been endeavoring by actual experiments to devise a generating apparatus suitable to the needs of an *x*-ray installation. In the choice of motors, he discarded oil and petrol engines as, for a variety of reasons, inefficient, and pinned his faith to a steam engine. With regard to a steam engine he says: "In this we have a machine which under recent improvements can be worked anywhere. These improvements have been brought about in the race for supremacy in actuating the machinery of the motor car, and consist of a new system in valve construction, increased power for size, and the introduction of a steam generator having none of the disadvantages of an ordinary boiler. The engine in itself is most compact and easily managed, and being of high speed, can be adapted to drive the armature shaft direct without the need of using belts and pulleys. The steam generator, which is commonly styled a flash boiler, is simply a helical of steel tubing suitably heated when the engine is running. Only sufficient water is injected into the coils to produce steam for each stroke of the piston, the water on entrance being immediately vaporized. Hence there is no boiler to burst through mismanagement, water or steam gauges to be attended to, only the heating of coils to be seen to. The fuel may be either coal, wood or paraffin, the latter requiring a special burner. An engine of this description, with steam generator and dynamo, could be obtained weighing approximately 3 cwt.

The *x*-rays are of more use in warfare than under any other circumstances. It frequently occurs that if a bullet can be exactly located, a successful operation may be performed and life saved. But the value of the *x*-rays in the field are obvious. To be available, however, in the utmost state of efficiency, an *x*-ray installation must be complete in itself, with means for charging batteries. If Lieutenant Bruce has succeeded in solving the problem of how to do this, he has performed a very important service.

News of the Week.

The Walter Reed Memorial Association has been incorporated under the laws of the District of Columbia. After careful consideration it has been decided that this is the most practical manner of securing a responsible board of trustees to take charge of the funds subscribed for a memorial to Major Reed, and to attend to the execution of the project when the necessary money has been received. The American Medical Association and the Association for the Advancement of Science have appointed committees which will no doubt cooperate with the association, and subscriptions to the fund may be handed to any member of these committees or they may be sent to Mr. Chas. J. Bell, President of the American Security and Trust Company, Washington, D. C., who has consented to act as Treasurer. It is thought that at least $25,000 should be raised, and it is probable that the exact character of the memorial will not be determined until a considerable portion of this amount is in the hands of the Treasurer. While it is felt that the non-medical public should contribute a considerable portion of the amount required, the main dependence must be upon physicians to arouse interest in the project by pointing out the important results of Major Reed's yellow-fever investigations. The president of the association is Dr. D. C. Gilman, president of the Carnegie Institute; the secretary is Gen. C. De Witt, U. S. Army, 1707 Twenty-first Street, N.W., Washington D. C.

Conference of the State Boards of Health.—The annual meeting of the State and Provincial Boards of Health was held in Washington last week. At the close of the session a resolution was adopted declaring that it is the duty of State Boards of Health to obtain such legislation and appropriations as may be necessary to secure the drainage of swamp lands and to treat the surface of shallow ponds and pools with such substances as are recognized as destructive to the life of mosquitos of all species. The election of officers for the ensuing year resulted as follows: *President*, John S. Fulton, Baltimore; *Vice-president*, M. K. Foster, San Francisco; *Treasurer*, J. A. Egan, Springfield, Ill.; *Secretary*, Gardner T. Swartz, Providence, R. I. The application of San Francisco for the meeting next year was filed, and probably will be accepted by the executive committee.

The State Hospital for Consumptives.—The Albany correspondent of the *New York Times* reports that by the beginning of next month the State Hospital for the treatment of incipient tuberculosis at Raybrook, Essex County, will be so far completed that eighty patients may be received. The wings of the hospital are yet unfinished, but when they are ready for patients 150 more can be accommodated. All applications of patients must be made to the Overseers of the Poor, for the intention is to give preference to the indigent persons who are suffering in the first stages of the disease. The overseer shall certify patients, who will then be examined by the local examiners, and will be certified by them, if a proper case, for admission. Because of the limited accommodations the rules will be strictly adhered to. Preference, all things being equal, will be given to earliest applications filed. Patients in advanced stages of consumption will not be admitted. The State has expended $215,000 for the construction of the hospital, and has appropriated $55,000 for

the maintenance and accessories. In addition to these sums, Dr. Willis G. MacDonald of this city secured an appropriation of $5,000 this year for the establishment of a camp for outdoor treatment.

Toy Pistols Prohibited.—The City Council of Cleveland, Ohio, on May 31, passed an ordinance making it a misdemeanor to use, give away, or sell a toy pistol or blank cartridge in this city on the Fourth of July. The ordinance is the result of recent action taken by the Academy of Medicine, which showed that a number of persons died from tetanus last year following the celebration of the national anniversary. A similar ordinance was passed in Cincinnati some months ago. Chicago, where the toy pistol has been barred for some time, is to allow no giant crackers, no revolvers, nor any explosive that has dynamite in its composition. To make amends to the small boys, however, the city authorities have contracted with an amusement company to set off fireworks in designated parts of the public parks, and to furnish free to all children who apply, a package of the old-fashioned small Chinese firecrackers.

Examination for Medical Interne at the Government Hospital for the Insane.—The United States Civil Service Commission announces an examination on June 29 and 30, 1904, at the usual places, to secure eligibles from which to make certification to fill at least two vacancies in the position of medical interne in the Government Hospital for the Insane, Washington, D. C., at $600 per annum each, and other similar vacancies as they may occur in that hospital. The examination will consist of the subjects mentioned below, weighted as indicated: 1. Letter-writing (the subject matter on a topic relative to the practice of medicine), 5; 2. Anatomy and physiology, 15; 3. Chemistry, materia medica, and therapeutics, 10; 4. Surgery and surgical pathology, 20; 5. General pathology and practice, 25; 6. Bacteriology and hygiene, 10; 7. Obstetrics and gynecology, 15. Age limit, 20 years or over. This examination is open to all citizens of the United States who comply with the requirements. Applicants must be graduates of reputable medical colleges. Applicants should at once apply either to the United States Civil Service Commission, Washington, D. C., or to the secretary of any local board of examiners, for application Form 1312. No application will be accepted unless properly executed and filed with the Commission at Washington prior to the hour of closing business on June 22, 1904.

A Japanese Translation of Dr. Knopf's Prize Essay.—The first copy of the Japanese translation of Dr. S. A. Knopf's International Prize essay, "Tuberculosis as a Disease of the Masses and How to Combat It," has just arrived in this country. The translation was made by Dr. Goro-Shibayama, and prefaced and annotated by Professor S. Kitasato. The Icelandic edition, ordered by the Danish government to be translated and issued by the same, appeared last December, and the Serbian edition a few weeks ago. This makes a total of eighteen editions in fifteen different languages which have appeared since the original German and American editions were published in 1900 and 1901 respectively.

The American Gynecological Society, at its meeting in Boston last week, voted to amend its constitution to read: The object of this society shall be the promotion of knowledge in all that relates to diseases of women, to obstetrics, and *to abdominal surgery*. The following officers were elected for the ensuing year: *President*, E. C. Dudley, Chicago; *Vice-presidents*, H. D. Fry, Washington, and H. C. Coe, New York; *Treasurer*, J. M. Baldy, Philadelphia; *Secretary*, J. Riddle Goffe, New York. The next place of meeting will be Niagara Falls.

Typhoid Fever in Indianapolis.—The Indianapolis *Journal* states that instead of there being only sixty-five cases of typhoid fever in that city during May, the returns have been concealed and the actual number of cases was about two hundred. The paper charges that the President of the Board of Health deliberately held back the greater number of cases reported although even the full returns would not have given the real number of cases, as many physicians neglect to report their cases. If these charges are true, the sooner there is a change in the presidency of the Indianapolis Health Board, the better for the city.

High Death Rate in New York State.—The bulletin of the New York State Board of Health states that during April there were 13,700 deaths, which is within 300 deaths of April, 1891, at the height of the influenza pandemic and within 600 of that of the month preceding, so that it stands the third highest on the record of monthly death rates. "It is further exceptional in that it is sequent to a series of months of excessive mortality. In the four months of this year there have been 53,000 deaths in this State, against 44,500 for the same months in 1903, and 43,300 in 1902. At this rate for the year there would be 160,000 deaths against 134,000, or against our average yearly mortality of recent past years of from 125,000 to 130,000.

Vital Statistics of Philadelphia.—For the week ended June 4 there were reported to the Philadelphia Bureau of Health 465 deaths, as compared with 494 for the preceding week, and 427 for the corresponding week of the previous year. Of the entire number, 165 occurred in children under the age of 5 years. Sixty-seven deaths were due to pulmonary tuberculosis, 38 to heart disease, 29 to pneumonia, 28 to nephritis, 21 to apoplexy, 19 to typhoid fever, 15 to gastroenteritis, 13 to congenital debility, 12 each to appendicitis, scarlet fever, and old age. There were reported also 102 cases of typhoid fever, 62 each of diphtheria and scarlet fever, and 10 of smallpox.

Low Death Rate in Chicago.—According to the weekly bulletin of the Chicago Health Department, the month of May passed into the history of that city with the lowest May mortality on record. During the first twenty-eight days there was a total of 1,990 deaths—furnishing an annual death rate of 13.44 per 1,000 population. The average rate of the previous decade was 15.63 per 1,000, so that May's record will be about 14 per cent. lower than the average and nearly 2 per cent. lower than the previous lowest—that of 1901, when it was 13.70 per 1,000.

Dr. Lapponi and the Pope.—It was rumored not long since that Dr. Lapponi had been dismissed as Physician to the Pope, the Pontiff, according to the reports, desiring the services of his Venetian physician, and also Dr. Lapponi, being a Free Mason, had insisted on the Pope leaving the Vatican, taking the ground that the Pontiff was no longer a prisoner. Dr. Lapponi, however, in an interview with the representative of the Associated Press, says he has never been asked to resign, and does not intend to resign, as he is apparently enjoying the entire confidence of the Pope. He adds that he is not a Free Mason, and has no intention of becoming one.

The Philadelphia Hospital.—The Dean of the Medical Department of the University of Pennsylvania calls our attention to an error in a recent refer-

ence in these columns to the examination for the staff of the Philadelphia Hospital. Among the first nineteen successful candidates, sixteen were graduates from the University of Pennsylvania, two from Jefferson, and one from the Medico-Chirurgical.

Dr. Arthur MacDonald and "The Sun."—A jury in the Supreme Court before Justice Dickey in Brooklyn has rendered a verdict for $20,000 in the libel suit of Arthur MacDonald against *The Sun*. The issue was whether Dr. MacDonald was an honest scientist and pursuing his work in the Board of Education at Washington in good faith and with pure motives, or whether, as asserted by *The Sun*, he was a counterfeit scientist, using his work as a cover for ulterior objects.

Treatment of Milk Fever in Cows.—A circular issued by the Department of Agriculture announces the discovery of a simple cure for "milk fever" in cows, an extremely fatal malady on stock farms, and prevailing in all parts of the country. Milk fever affects well-nourished, heavy milking cows, and is characterized by the complete paralysis of the animal shortly after calving. The cure, according to the circular, is simple, and consists merely in the injection of sterilized air into the udder through the teat.

Cincinnati College of Pharmacy.—Thirty men received their diplomas from this institution last week. Addresses were made by Congressman J. H. Bromwell and by the president, Dr. Julius H. Eichberg. Later a banquet was served.

A New College in Los Angeles.—It is rumored that a new medical college has been organized at Los Angeles, Cal., to be known as the College of Physicians and Surgeons. It will be conducted in connection with the Angelus Hospital, also a new institution not yet built. Those named as being active in the organization of the new college are Drs. C. B. Nichols, Charles W. Bryson, Frederick C. Shurtleff, James H. Seymour, M. R. Toland, and J. H. Shields.

Hydrophobia.—The Director of the Chicago Municipal Laboratory, Dr. J. F. Biehn, recently sent out a warning of danger of an epidemic of rabies. Muzzling of all dogs that appear in public is the remedy advocated by him. He has just completed analyses of the bodies of three dogs, and has found that all had hydrophobia.

Prosecution of a Quack.—The State Board of Health of Illinois has prosecuted an advertising "doctor" charged with violating the medical practice act by the use of "torture needles and lotus-oil injections."

The John W. Pray Prize.—At the recent meeting of the New Hampshire State Medical Society, the John W. Pray Prize for the best essay on a medical subject was awarded to Dr. Frederick L. Hills, First Assistant Physician at the New Hampshire State Hospital. The subject of the essay was "The Sanatorium for Incipient Pulmonary Tuberculosis; Its Aims, Methods, and Results."

Commencement Exercises of Milwaukee Colleges.—The Wisconsin College of Physicians and Surgeons graduated a class of twenty-nine on May 25. The doctorate address was delivered by Dr. Arthur J. Burgess, and Dr. A. H. Levings, the president, conferred the degrees. A class of twenty-three was likewise graduated from the Milwaukee Medical College April 30. The degrees were conferred by the president, Dr. William H. Earles.

Runge Memorial Meeting.—Memorial services for the late Dr. Edward C. Runge, formerly superintendent of the St. Louis Hospital for the Insane, who died recently in that city, were held on the evening of June 2. E. C. Elliot presided and Drs. Frank R. Fry, Gustav Baumgarten, Robert Luedeking, Otto Heller, and Judge O'Neill Ryan spoke of the life and work of Dr. Runge. Dr. C. B. Burr also spoke in warm terms of his admiration for the high qualities possessed by Dr. Runge. The following resolutions on the life and work of Dr. Runge were adopted: "This assembly recognises in the personality of Doctor Runge a rare combination of qualities consisting of a brilliant mind, a high character, devotion to duty and friends, and a fearlessness which was admirable. We invite the people of this city and State to the obvious lesson to be derived from a careful study of this man's life. He was lofty without being impractical, he was noble without being egotistical, a well-rounded man and one whose death should be mourned by all."

Obituary Notes.—Dr. FREDERICK C. SCHAEFER, professor of clinical surgery in the Chicago Post-Graduate Medical School, surgeon-in-chief of St. Hedwig's Hospital, and gynecologist to St. Elizabeth's Hospital, died suddenly on June 3, at his home, from acute gastritis. He was born in Galena, Ill., in 1849, and moved to Chicago in the early seventies. He received his professional training in the Chicago Medical College. After being graduated in 1876, he became professor of anatomy. When the institution was merged with Northwestern University, Dr. Schaefer continued as a member of the Faculty. At the time of his death he was also consulting surgeon to the Mary Thompson Hospital for Women and Children. He was a frequent contributor to medical journals. He was also a member of the American Medical Association, of the State and local medical societies. He leaves a wife, one son, and three daughters.

Dr. ROBERT REIMAN died at Egg Harbor City, N. J., on June 4, as a result of cerebral hemorrhage, at the age of eighty-four years.

Dr. MATTHEW LEEPERE died on June 6 of nephritis, Glen Cove, L. I. He returned recently from the Philippine Islands. He was born in Arkansas in 1854. At the age of eighteen he became Indian interpreter for the United States Government and three years later was made a commissioned officer of the Fourth United States Cavalry. For ten years he saw active service in the West and on several occasions received honorable mention for bravery in battles with the Indians. At the expiration of the ten years he retired from the army and took up the study of medicine. He made a specialty of throat and ear diseases. He went to Chicago in 1882 and remained there until the Spanish War broke out, when he enlisted as a volunteer surgeon. He remained in the army until the close of the war in the Philippines. For the last year and a half he had been president of the Board of Health of the island of Mindoro. He was enthusiastic over the Philippines and believed there were great possibilities for the islands. He was taken sick on January 1, and as his condition did not improve he decided to return home. Dr. Leepere married Miss Mary Elsie Norton in Holland, N. Y., in 1890. She survives him.

Dr. B. A. WRIGHT, a native of New York, died on May 17, in Los Angeles, Cal., at the age of eighty-one.

Dr. H. C. VAIL, an aged retired physician of Long Beach, Cal., died suddenly at Los Angeles, May 18. He was a native of New Jersey.

Dr. GEORGE WASHINGTON BROOKS died in this city on June 3, from apoplexy, at the age of (87) years. He was long in active practice in New York, but retired about eight years ago.

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent.)

ANNUAL ORATION OF THE MEDICAL SOCIETY—X-RAYS IN RELATION TO TUBERCULOSIS AND CANCER—MIDDLESEX HOSPITAL AND CANCER—LONDON UNIVERSITY PRESENTATION DAY.

LONDON, May 20, 1904.

THE annual oration of the Medical Society of London was delivered on Monday by Sir Isambard Owen, who took for his subject the "Future of Medical Education in London." Sir I. Owen is sub-dean of the faculty of medicine of the London University and deputy chancellor of the University of Wales. He should, therefore, be well able to discourse of this subject, and his experience as a teacher in one of our hospitals is an additional qualification for his task. The oration was listened to with close attention by an interested audience, and a considerable proportion agree with his views. He drew a contrast between the provision for higher education here and abroad, in the course of which he mentioned a number of the munificent endowments in the United States, and lamented the little that we can show in comparison. One of the most important points put forward as a definite object for the future was the realization of the scheme of the London University for an institute of the medical sciences which would undertake the teaching of the preliminary and intermediate subjects of the medical curriculum. This would probably in time supersede the hospital schools so far as these subjects are concerned and leave the clinical to be continued as at present. Certainly some advantages would result to the students who would thus become members of the University, and would, if they liked, proceed to its degrees without a number of the vexatious and unreasonable restrictions imposed by the old London University, which was, in fact, a mere examining board hedged in by regulations most difficult to comply with.

But although many are prepared to hold that the institute would be the best solution of our difficulties, others are doubtful and think it might easily become a mere competitor of the old schools. It is possible, however, that the institute, if once established, would eventually absorb all the scientific education of the medical profession. The Senate has adopted the scheme, and the institute may be regarded as the child of the university. But there is one great matter to settle—funds. It is estimated that £375,000 will be required to adequately endow the institute. Where is the money to come from? Americans would very soon come forward for such an object in the United States. I am afraid that in the old country it will take considerable time and earnest appeals to carry out the scheme.

The Clinical Society had two papers before it dealing with *x*-rays from two different points of view. The first, by Drs. Stanley Green and W. H. Brook, discussed the use of the rays as a factor in the diagnosis of pulmonary tuberculosis, and was illustrated by lantern slides. From two and one-half years' work the authors concluded that the rays afforded substantial assistance in the diagnosis of very early phthisis, for by means of a screen examination unilateral limitation of the movements of the diaphragm would be revealed. The transradiency of lung tissue, or the presence of scattered areas of shadow, also afforded important indications. The slope and shape of the ribs and the width of the intercostal spaces were further points of importance to notice. They had been able to show the presence of cavities, and even of fibrosis, in certain cases. In bilateral cases an examination by *x*-rays might demonstrate the presence and even the extent of disease before it could be recognized by percussion and auscultation. But the method should only be regarded as an adjunct to these and to the microscopical examination of the sputum. This conclusion was commended by the speakers who followed, some of whom expressed a fear lest the older-tried methods are in danger of being neglected, for it is hardly likely that they will ever be supplanted. At the same time, as a means of realizing more vividly the physical condition, and, perhaps, of recording the progress of the disease, the value of skiagraphy must be recognized. Ocular demonstration of a morbid condition must be of value, but it is of importance to remember that the shadows are not infallible, and skiagrams require to be interpreted with care.

The second paper dealt with cancer instead of phthisis and the use of the rays in treatment instead of diagnosis. It was communicated by Dr. A. E. Peters, and consisted of a description of two cases of recurrent carcinoma of the breast which had been treated by *x*-rays. In the first the treatment had been continued for twenty-two months. The subcutaneous nodules and the ulceration both disappeared, but only to return on cessation of the treatment, though in a state of diminished activity. Eventually growths appeared under the skin, at the back of the thorax, and these nearly disappeared under exposures to the rays. The breast and glands of the opposite side became involved. The patient felt the pain relieved by the treatment. In the second case subcutaneous nodules and pleuritic thickening improved for a month under the treatment, but the patient died soon after from thoracic involvement. A tendency for scar-tissue to break down under the treatment was observed.

In the discussion on this paper it was generally recognized that the rays had a decided influence in promoting the removal of nodules, breaking down scar-tissue and degenerating cells, perhaps even changing the characters of a growth or preventing a tendency to recur. But then the patient would often succumb from secondary deposits elsewhere. In inoperable cases the rays may give the patient the comfort of relief from pain, but when cancer is discovered early enough the prevailing opinion seems to be in favor of excision.

The Countess of Derby held a meeting at Derby House on behalf of the Middlesex Hospital, at the close of which it was announced that contributions to the amount of over £8,500 had been promised. Sir Douglas Powell said efficiency was the watchword of the hospital, especially in reference to the cancer department. Mr. Pearce Gould made quite an optimistic speech in regard to this. He firmly held there was good hope of discovering the cause and then they would find a cure. As there were cases of cancer which got well spontaneously, and that fact proved that the disease was not incurable. The *x*-rays had a remarkable effect on some cases, and the work done in the research laboratory was most encouraging. It was too technical to dwell upon before that audience, but there was one point he would like to inform them about—the supposed hereditary nature of cancer. This had been grossly exaggerated. The careful survey of the facts they had accumulated proved that if heredity had any influence at all it was only very slight. Many people feared that if any of their relatives had suffered from cancer they would almost certainly have it. This was a gross exaggeration, and they should pay little heed to any such supposition.

On Wednesday the reorganized University of London celebrated its presentation day with almost mediæval pomp and circumstance. An imposing procession was formed of all the leading officials, the senators and guests, and passed on to the Great Hall, which was crowded with graduates and undergraduates, the number of women among them being notable. The presentation for degrees and honors occupied little more than half an hour, and the procession was reformed and passed out amidst a round of applause. The new organization seems successful so far as numbers go, for the report stated that the total number who entered the university in the last official year was 3,261. Further, the number of entries for the matriculation examination to be held next month is 3,551.

LETTER FROM THE PHILIPPINES.

(From Our Special Correspondent.)

INCREASE IN SMALLPOX—VACCINATION PROBLEMS—THE WORK OF THE OFFICIAL VACCINATORS—DISTRIBUTION OF VACCINE MATERIAL.

MANILA, March 29, 1904.

DURING the past few months the usual annual increase of smallpox accompanying the development of the dry season has been noted. The population of Manila itself has been well protected by vaccination, and but few cases of smallpox occur except in transients in spite of constant importation of the infection from the provinces. To reduce the liability to the latter, the quarantine physicians have lately been carrying out systematic vaccination among the crews of the vessels running to and from Manila, and so far have performed ten thousand vaccinations which were successful or which were repeated until the fact of immunity was established. In the provinces, however, in a large proportion of which the population is in great part unvaccinated, there have lately been several smart epidemic outbreaks, this being especially the case in respect to the provinces of Ilocos Norte, Tayabas, and Misamis. In all these epidemics the disease was stamped out by practically no measures other than that of vaccination of the entire population. In Misamis the military and civil medical authorities coöperated in the suppression of smallpox, which had developed into a serious outbreak. Communication with the infected towns of this province was very imperfect, and of a large amount of vaccine virus forwarded a considerable part went astray or spoiled en route. Arm-to-arm vaccination was therefore generally practised by the vaccinators with no ill results so far as known. The

Filipino, when vaccinated desires a well marked local reaction and does not discriminate between true vaccina and the reaction due to a local pyogenic infection. Much of the virus used by the Spaniards was inert, and with the desire of promoting its efficiency a custom has grown up among the lower classes of covering the vaccination abrasion with a poultice of boiled fish, which is left on for a couple of days or so and can be counted on to infect the skin lesion so thoroughly as to cause intense local inflammation. Vaccinators find considerable difficulty in successfully opposing this custom and in inculcating the new doctrine of cleanliness. Aseptic bandages are frequently removed to be replaced by the fish poultice.

As a general rule, the Filipinos are fully convinced of the efficacy of vaccination in the prevention of smallpox, and the work of vaccination probably encounters less opposition from them than from an equal number of white residents of the United States. A concrete example of their appreciation of the measure exists in a life-size statue which stands in the plaza before the Government building and is representative of and dedicated to the King of Spain under whom vaccination was first performed in the islands. It was erected a number of years ago from the voluntary contributions of the Filipinos themselves. Of course among the most ignorant classes and among the wild tribes the value of vaccination is not understood, and conditions are encountered similar to those mentioned by Kipling in his story having to do with the vaccinating of the Satpura Bhils. Quite recently vaccination had to be discontinued in the center of Panay Island by reason of the ignorant people, deceived by agitators against the Government into believing that vaccination was the cause of cholera, assaulting the vaccinators and forcing them to flee for their lives. The Moros have, rather unexpectedly, taken kindly to vaccination, as performed under the army surgeons in the vicinity of the few military stations where it has been practised on the surrounding native population, and a virgin population of some half a million Mohammedans is awaiting the advent of the vaccinators in the Moro country. In the Island of Negros report says that the wild tribe of the Babuayanes, living in the mountains, was almost exterminated by smallpox during the years 1899-1900, and this disease is stated to be a chief factor in the gradual but steady disappearance of the Negritos. Among the Igorrotes the smallpox infection is always prevalent and a prominent cause of mortality.

The work of carrying out vaccination in the city of Manila and throughout the provinces has lately been reorganized, and a carefully prepared plan elaborated under which this work will in the future be carried out. Up to the present time there has been little system in the execution of this work and no check upon its accuracy. In the provinces, vaccinators were appointed on the recommendation of the local doctors, furnished with vaccine virus and allowed to operate with practically no supervision. There was no minimum day's work required to be performed, and the results obtained were inadequate as compared with the expense involved. The records of the vaccination work were prepared in so many ways as to render it impossible to reduce them to a comparable basis of statistics for the entire islands, and reports of the work done were far less frequently rendered than missing. Where such reports were furnished, there was often reason to believe them to be unreliable from the desire of the vaccinator to make an exceptionally good showing. As the provincial vaccinator received his travel and subsistence expenses, there was a constant temptation to overcharge in this respect. and the disallowance of such excessive accounts caused trouble and annoyance to all concerned. It is also to be more than suspected that undesirable and incompetent men were frequently recommended for appointment as vaccinators by the local native doctors, who regarded such positions, well paid from the insular funds, as comfortable berths for political friends or needy relatives. The frequency with which smallpox was reported from districts recently supposed to have been properly gone over by vaccinators, showed the absolute necessity for radical reorganization.

The system in operation under the Americans in the provinces was highly faulty, but was a marked advance over the trivial, faulty, and impotent methods of the Spanish health authorities, whose records for the year 1894 show that the reported performance of only two or three vaccinations a day was regarded as a sufficient amount of work for a vaccinator. Finally, and of much importance, the means of communication throughout the islands are still so poor that unless vaccine virus is shipped with unusual precautions, it is often liable to become spoiled before being placed in the hands of a vaccinator operating in a remote province.

In Manila the vaccination work since the American occupation has been far better carried out than in the provinces, though still far from being perfect. A better class of vaccinators was obtainable. their work was supervised to a certain extent and the vaccine virus used was fresh. Fair records were kept of the work and show that more than 150,000 persons were vaccinated in the city during the year 1903. This amount of work, as shown by the records, is more than three times greater than the amount of vaccination work carried out by the Spaniards, in the city of Manila, during the entire five years preceding the assumption of American sovereignty over the islands. The recent work in the city has practically resulted in the protection of the inhabitants against smallpox, and as already stated, such cases as develop now largely occur in the less efficiently vaccinated transient population.

Under the new plan lately adopted, the general work of vaccination is under a physician of the Board of Health, whose office is subdivided into two divisions, one having to do with personnel, orders, reports, records and statistics, and the other devoted to the supply and distribution of vaccine virus. A chief vaccinator is in charge of the former class of work for the archipelago. For the city of Manila there are thirteen vaccinators and four inspectors of vaccination, one of the latter being in charge of the personnel of the city. Each vaccinator is required to average forty vaccinations daily, going from house to house, and each inspector is required to inspect one hundred vaccinations daily, as to their success. On vaccinating a person, the vaccinator signs and issues a red card, giving the name, age, sex, and address of the person vaccinated and the date of vaccination. The inspector takes up this red card on inspecting the vaccination, and if the latter was found to have been unsuccessful he issues a white card stating the fact and giving the above information. If the vaccination is successful, a blue card is issued, which is accepted as evidence that further vaccination of the holder will not be required for a period of two years. Careful records are kept on loose blank form sheets, which, after being filled out, are turned in to the various district sanitary stations, where they are bound together in permanent records covering the population of the respective sanitary districts. These sheets are signed by the vaccinator who enters thereon the name, address, sex and age of the person, the date of vaccination, and the existence or not of evidence of previous successful vaccination. These sheets are also signed by the inspector before being finally turned in to the district sanitary station, and the success of the vaccination noted and any remarks entered thereon. From these records almost any statistical data may be compiled, and full information as to the protection by vaccination of any person in his district can always be secured by the district medical inspector. A daily summary report, on a printed form sheet, is compiled from these records and forwarded from each district sanitary tation to the chief vaccinator for the city, who compiles them into consolidated weekly and monthly numerical summary reports and forwards them to the office of the Board of Health, where they are incorporated into the vaccination statistics for the archipelago. In the vaccination work of the city, the districts are gone over systematically, street by street; once in three months the birth records of the district are gone over and the unvaccinated infants of suitable age sought out and vaccinated, and especial effort is made to vaccinate persons not vaccinated during the previous calendar year.

In the provinces, practically the same blanks forms are used and the same reports are rendered as in Manila, so that the data thus furnished can be consolidated statistically, for the islands. The vaccinators are uniformed, and trained in Manila and sent out from there, being placed under the control of the provincial health officer as soon as they report for duty in his province. He assigns them to stations and is responsible for the efficient performance of duty by them. Each province is districted and a sufficient number of vaccinators will be stationed in each district to accomplish the vaccination of the entire population of such district within a fixed time. As in the provinces the law requires that persons to be vaccinated must present themselves at a place and time designated as the one in which the operation is to be performed, more persons can be vaccinated than where the vaccinators must themselves go from house to house. The minimum number to be vaccinated is fixed at sixty per man per day and the number to be inspected is one hundred and fifty per man per day. One hundred vaccinators are allowed for the provinces, in addition to which the law requires that the more than three hundred physicians who are presidents of local health boards shall vaccinate persons within their respective municipalities. The average numbers to be vaccinated daily by such physicians, when the general vaccination of a province or municipality is ordered, is fixed at fifteen per man per day, a greater number unduly interfering with the performance of other duties by such physicians. The records of vaccination are made on form sheets almost identical with those used in Manila, and after being filled out by the vaccinators and inspectors, are stitched together and filed with the Secretary of the municipality as a public municipal document. The re

ports and numerical summaries are rendered on the prescribed form blanks at the conclusion of the work of vaccination and inspection in each municipality, and are forwarded to the president of the provincial board of health, who consolidates all reports received from the various municipalities of his province on a provincial blank form and forwards the same to the Board of Health in Manila, where the various provincial and city reports for each calendar month are consolidated into a table for the islands. All reports from municipalities are sent through the local presidentes, or mayors, who are obliged to endorse thereon whether they believe the reports to be accurate and whether the conduct and efficiency of the vaccinators and inspectors were satisfactory while in their municipalities. As soon as a province has been thoroughly gone over and all available persons vaccinated, the vaccinators are moved to another province and the same procedure entered upon. The provinces first vaccinated are those in which smallpox exists, and the first towns selected within such provinces are those in which the disease prevails. Contacts are first of all sought out and vaccinated. Under this plan it is estimated that, using the services of the local health officers of municipalities, an aggregate of about two million persons can be vaccinated in the space of twelve months, which would mean that about four years would be required, at the same rate, to vaccinate the whole population of the archipelago. It is estimated that this vaccination can be carried out at a cost of less than five cents United States money, for each vaccination so performed.

In connection with this general plan of carrying out vaccination work, a satisfactory method of supplying vaccine virus has been worked out, by which vaccine substations in the remote provinces are established provided with large ice boxes and supplied with ice from Manila, or other convenient point for preserving the virus. Vaccine virus is sent on ice in small portable ice boxes from Manila to these provincial supply stations, where it is kept on ice until distributed to the vaccinators, the small portable ice box being at once returned empty to Manila to receive another shipment. In certain cases, in which water transportation is available and vaccinators are working at a considerable distance from such a provincial vaccine supply station, the portable ice boxes are reiced, if necessary, and sent direct to the vaccinators with their contained supply of vaccine virus. For short distances or to places in ready communication with Manila, as along the railroad or the shore towns of the neighboring provinces, vaccine virus will be sent out by mail, as heretofore. An elaborate scheme for distribution has been worked out in connection with post-office routes, the railroad and the lines of coastwise steamers, army transports and coast guard boats, by which it is known how and when any given municipality may be reached, so that supplies of fresh vaccine virus can be forwarded to it without unnecessary delay in shipment. This matter of supply of vaccine virus is one of much difficulty and great practical importance, as in the past the work of vaccination has been seriously impaired by difficulty of supply and deterioration of vaccine virus en route.

This proposed general vaccination of the islands is unquestionably the greatest undertaking of its kind which has ever been projected, and, from lack of ready means of communication, it will meet with difficulties which will scarcely be encountered elsewhere. Its success will greatly redound to the credit of those by whom it has been planned and executed.

IS LEPROSY CURABLE?

To the Editor of the Medical Record:

Sir: I notice that the Medical Record as well as the *British Medical Journal* has dignified the newspaper account of a recent lecture of mine with editorial comment. I feel that, perhaps, an authoritative statement from me might be acceptable.

The Louisiana Leper Home has never been adequately brought before the public of Louisiana; the State Legislature has always failed to supply adequate funds for the proper maintenance of this institution. With the object of stimulating local interest purely, I delivered a public lecture before the Alumni Association of the Jesuits' College here, an institution of no mean note. The newspapers reported that lecture sensationally, and I had no opportunity of censoring their account. Evidently some parts of their account were considered as general news, and the Associated Press distributed these in a more sensational way. I regret this, as a public lecture is not the place to exploit medical achievements, and my position in New Orleans did not need any advertisement of that sort.

My lecture dealt with the historical relation of leprosy, and a description of the past and present conditions of the leper colony in Louisiana. It was illustrated with lantern slides, and the whole topic was discussed in a dramatic way. In concluding, a section of the lecture was devoted to the caption, "Is There Any Hope for the Leper?" Under this head I related the fact that within two years every case, not too far gone, at the Leper Home had been benefited; that in three cases the evidences of the disease had almost disappeared. I further stated that during ten years my assistants and myself had removed all evidences of the disease in nearly a dozen cases. I had made no statement as to the remedy employed as I did not feel that that was the place to discuss technic.

The notoriety which has attached to the report of my lecture I trust will entitle me to receive adequate consideration at your hands for the present communication. I wish to state that *I know no specific for leprosy; I have discovered no cure.* I propose reporting these cases in which the evidences have been removed. I shall do this in a proper medical periodical.

I wish to state that in twelve cases all evidences of the disease have been removed—in one case, for the past eight years; the others have been free of evidences of the disease for periods ranging up to two years since. None of these cases have been at the Leper Home.

The treatment employed has been various, but, in most instances, I have used maximum doses of chaulmoogra oil, and as crude as I can get it in the liquid state. Some patients have taken as much as two drachms at the dose. The patients know that they have no evidence of the disease, and some of them follow their occupations as if nothing were the matter with them. All of them have maintained treatment since the evidences of the disease disappeared.

I have made no claim for anything more than the removal of the evidences of the disease. I have not stated that I had discovered a cure for leprosy. I do not know, nor does any one know, whether the disease will recrudesce in any of these patients or not.

The bacteriological examination has been negative in several instances in which such examination has been repeatedly made in these cases referred to.

As the founder of the Louisiana Leper Home and personally cognizant of the fact that the disease is more extant in Louisiana and neighboring States than is usually allowed, I have lost no opportunity in making the purpose of the Home known and felt. I regret any misapprehension that may have arisen. Finally, let me say that Unna of Hamburg, Crocker and Hutchinson in London, have announced cases in which all evidences of the disease had been removed by treatment, and I trust that when my report is made it will only stimulate others to treat the disease persistently and attentively.

Isadore Dyer, M.D.

New Orleans, La., May 27, 1904.

Enuresis in Children.—Percy Lewis states that the variety of causes to which this condition has been attributed and the very diverse treatments which have been recommended for its cure, suggest that its pathology has not been accurately studied. The subjects of this complaint are mostly unhealthy in aspect. The treatment which has for some years been successfully carried out by the writer was suggested by the consideration of a similar condition which occurs in infants fed on starchy foods. Such children always pass a larger amount of urine than normal. When their starchy food is cut off this symptom disappears. It is the same with victims of enuresis. In most cases a rigid anti-diabetic diet removes the symptom in a few days. The cause, however, due to a general depression of health produced by an excessive starchy diet, requires general tonic treatment at the same time. During the cure, starchy food may usually be allowed for breakfast without "accidents" occurring at night. Without any other treatment, hospital cases are relieved often at once and finally cured by being taken as in-patients and fed on the ordinary hospital diet. In private cases even small quantities of bread or cake given at dinner or tea early in the treatment cause the bed-wettings to recur. In about three to four weeks, sometimes sooner if the tonic treatment is pushed as well, a normal diet may be given without enuresis happening. While not wishing to contend that enuresis is a condition of rickets, the writer is of the opinion that it is a weak bodily condition caused by an excessive starchy diet and associated with inability properly to digest that excess.—*The British Journal of Children's Diseases.*

Progress of Medical Science.

The Boston Medical and Surgical Journal, June 2, 1904.

Disinfection of the Clinical Thermometer.—Francis P. Denny calls attention to a method of disinfecting the clinical thermometer by putting a few drops of formalin into the thermometer case. Two or three drops of formalin (40 per cent. solution of formaldehyde) are put into the case and are absorbed by the cotton, which will remain moist a number of days. Formaldehyde gas is freely given off from the formalin, but is confined in the air-tight chamber of the case. The small size of the chamber, the high humidity, and the high temperature, if the case is carried in the vest pocket, furnish conditions very favorable for the disinfectant action of formaldehyde. Where the thermometer has been used for a patient known to have a contagious disease it is best to disinfect it outside the case, or at least fresh formalin should be added and the thermometer exposed to the gas several hours before being used again. By this method the thermometer is always disinfected after it is used with no loss of time to the physician, except the time it takes once in two weeks to add three drops of formalin to the case.

Journal of the American Medical Association, June 4, 1904.

Abdominal Pain and Pneumonia.—S. A. Foote relates the case of a young woman of twenty years. Its interesting features were the absence of all signs pointing to involvement of the lungs until the third day of the illness. The principal initial symptom was pain in the right iliac fossa with evidences of excessive tenderness on slight pressure. There was no swelling but some rigidity was noted in the muscles superimposed on the appendical area. Later the tenderness spread over the entire abdomen. Operation was prepared, but on account of amelioriation of symptoms deferred. On the fourth day of her illness a severe pain, preceded by chilliness, was felt about the right nipple. Examination of the chest now revealed consolidation of the right lower lobe: termination by crisis occurred on the seventh day from the first onset of the sickness.

Medical News, June 4, 1904.

Scurvy in Infants.—William Fitch Cheney declares that scurvy is a disease in which proper treatment works a miracle. It has no tendency to spontaneous recovery, but when recognized and given the proper care, improvement is immediate and cure is surprisingly rapid. No other disease affords the physician a better prospect for brilliant results. As to treatment, three measures are indicated: (1) Discontinue the proprietary food. Substitute a mixture of fresh milk diluted with water or with oatmeal water. (2) Give fresh orange juice, in dose of one or two teaspoonfuls three times a day. It is surprising how babies with scurvy take to this and seem to enjoy it. (3) Give freshly expressed beef juice, squeezed from rare steak, in dose of one or two teaspoonfuls three times a day. (4) Give no drugs at all.

Notes on the Epidemic of Cerebrospinal Meningitis.—Henry Dwight Chapin, in describing this disease, says that the onset is fairly abrupt, differing thus from all other forms of meningitis. The severity of the initial symptoms is apt to stand in some relation to the type of the attack. There is severe pain in the head and back of the neck. The typical retraction of the head is an early symptom, usually noted on the second or third day. The posture is characteristic. With the opisthotonos, the thighs and legs, and even the arms and hands, are apt to be in a condition of more or less extreme flexion. After this characteristic beginning, cerebrospinal meningitis is most irregular in its manifestations, particularly in the epidemic type. The general course and duration are most irregular. In some cases the brain is permanently injured by the ravages of the disease. The special senses may suffer loss or permanent disability. The cause of the epidemic form of this disease is the Diplococcus intracellularis, which is found in the fluid procured by lumbar puncture. It is usually turbid when drawn. The manner in which the germ gains access to the cerebrospinal meninges, as well as its port of entry, appears to be uncertain. The death rate is high. The disease does not seem to be limited to any one section of the city, but generally occurs in the poorer quarters. It seems to attack by preference those living in unfavorable hygienic surroundings, or those whose systems are exhausted, especially if they live in depressing environment. It does not behave like a contagious disease, but rather appears in comparatively isolated localities. Most of the epidemics have extended principally in winter.

New York Medical Journal, June 4, 1904.

A New Operation for Puerperal Sepsis.—Swithen Chandler gives the directions for the operation as follows: Make an incision posteriorly to the cervix in the posterior vaginal wall; then pass a pair of long blunt-pointed forceps, slightly curved, in the cervical canal, up into the cavity of the uterus; then puncture the posterior wall of the uterus in the center, near the top of the uterus. Then introduce with two fingers a piece or strip of iodoform gauze through the posterior vaginal opening previously made, clasp the gauze with the forceps, and drag the same through the uterine wall and out through the vagina. Repeat this by puncturing the uterus on each side, but posteriorly and just about the middle of the body of the same, drawing the gauze through the same as in the first attempt.

Atheroma and Aneurysm of the Abdominal Aorta at the Age of Twenty-one Years.—The patient of C. R. Andrews was a young white male. He had been sick for nine weeks before coming under observation and lived only seventeen hours after admission to hospital. He was probably syphilitic, though a denial was made of this infection. Before death a mitral regurgitant murmur was present, and the autopsy showed a large warty growth capped with calcareous deposits on the upper surface of the mitral valve. The aortic cusps were also sclerotic and thickened. The arch of the aorta was atheromatous and studded with several ulcers, which had extended through the intima. The arteries of the extremities were atheromatous, though not so markedly so as the arch of the aorta. Just above the location of the cœliac axis was a sacculated aneurysm 4.5 cm. in diameter. The thrombus within the aneurysmal sac was rather firm and laminated, the blood having coagulated in concentric layers at different periods of time. The patient complained of no pain, and gave no symptoms which would have led one to suspect the condition. In addition to the above lesions there were infarctions in the spleen and kidneys, together with interstitial nephritis, pleuritic adhesions, and adhesive pericarditis.

American Medicine, June 4, 1904.

The Conservative Treatment of Acute Appendicitis.—A. W. Morton believes that the leucocytes are of importance in conjunction with the other symptoms, in not only arriving at a diagnosis, but in differentiating appendicitis from other diseases. He believes that a count of 20,000 or more not only indicates that pus has formed but in conjunction with other symptoms, that it has passed beyond the confines of the appendix, and that there is an effusion into the peritoneal cavity, and that it is one of the symptoms that not only confirms the diagnosis, but should deter the surgeon from operation as long as the count remains above 20,000. The pulse remaining above 116, and the other symptoms exaggerated are special indications that operation should be postponed until the general condition is better. This is the hopeless class of patients which give the ever-ready surgeon his mortality. The writer believes that rest is especially indicated in the treatment of appendicitis. During the past two years he has treated forty-five patients with acute appendicitis, and twenty-seven of the patients were operated upon during the first to the fifth day, with one death. Two were treated through the attack, and refused operation. Sixteen of the patients were treated from four days to two weeks, and then operated upon, with one fatality.

The Leishman-Donovan 'Blood Parasites (a'Synopsis).—Joseph McFarland, in referring to the studies of Manson and Low, states that they confirm and supplement the descriptions of the earlier observers, and seem to disprove completely Laveran's statement that these bodies are parasites of the red blood-corpuscles, and a species of piroplasma. Although the parasites are often encountered superposed on or underlying a red blood-corpuscle nothing has been at any time seen to suggest that they are inside the corpuscle. The Romanowski stain gives the best results. These workers do not doubt that the frequency with which the body was found by Donovan and the frequent occurrence of chronic febrile splenomegaly, indicate that this parasite is important in tropical pathology. The writer tapped a patient's liver, and found in the small quantity of blood so obtained, numerous single or double parasites, but no zooglea masses. This fact seems to point to the biliary ducts as the channel through which the parasites escaped to gain subsequent freedom by passing out of the body with the fæces, but repeated examination of the fæces have been negative. Centrifuged urine has yielded no parasites. In the parasites obtained from the liver, in 90 per cent. of them the nucleus was either extended and swollen, or was in process of extension. Possibly due to the dilution of the blood with normal salt solution. The parasites could not be cultivated in blood agar.

Influence of Old Age, Diabetes, Arterial Sclerosis, and Gout on the Healing of Wounds.—Wells P. Eagleton declares that the essential consideration in operating on old people, aside from damaged kidneys, heart, etc., is

guard against shock. After eliminating this, quite as apid union as in younger patients may be anticipated. he writer believes that in considering a case for surgical peration in a diabetic subject, there should be less attention paid to the presence of sugar in the urine, and ore to the technique: (1) By remembering the special ability of the tissues to infection, and so practising absolute sepsis. Antiseptics have no place here. (2) By membering the extremely low vitality of the tissues, l trauma not absolutely necessary should be avoided.) By remembering the frequent association of arterial clerosis. Interfere as little as possible with the blood-pply. (4) By remembering the liability of nerve deneration, and preventing the possibility of even slight ressure over the site of operation. Any violation of ese rules in a case of diabetes would probably terminate isastrously. The danger of a complicating atheroma ordinary senile gangrene in a diabetic patient.

The Lancet, May 28, 1904.

Three Cases of Suprarenal Apoplexy in Children.—F. angmead reports the cases, and reviews the various heories of causation. Most of these cases are due to sphyxia and trauma, but there is a third class due probbly to some toxæmia This class is characterized by a irly definite train of symptoms. A child previously ell is suddenly seized with acute abdominal pain and omiting and rapidly becomes seriously ill. The temperature rises and an exanthem is often suspected. No haracteristic rash, however, appears, although sometimes here is purpura. In a few cases there are other hemorrhages resembling the "purpura fulminans" of Henoch, onvulsions generally supervene, the patient becomes moribund, and death occurs in a period which may be ounted by hours. The toxæmia theory is favored by the close resemblance between the clinical records of these cases, and those of acute specific diseases of a malignant type, and also there is no lack of experimental evidence suggesting a toxic origin. On the other hand, bacteriological evidence is negative, and in no case is there evidence of exposure to any source of infection, and furthermore, while profound toxæmia, the result of specific infection as in diphtheria and summer diarrhœa, is a common cause of death in children, cases of hemorrhage into the suprarenals are very rare. If it be an infection, presumably it is a special infection of unknown origin.

British Medical Journal, May 21, 1904.

A Case of Acute Tetanus.—Arthur Dobson reports this case, which is of interest for several reasons. The incubation period was only eight days. The period between the first symptoms and death was twenty-four hours. This was probably accelerated by the presence of a heart lesion —there was a well-marked mitral murmur, systolic in time. The abdominal muscles remained flaccid throughout. The patient was a man of twenty-three years, suffering from injury to the right foot. Lisfranc's operation was performed with the above results. The stump looked healthy and showed no signs of suppuration. It was dressed with hot boracic fomentations from the first.

The Relative Advantages of Suprapubic and Perineal Prostatectomy.—Edward Deanesly summarizes the principal advantages which prostatectomy by the perineal method possesses compared with the suprapubic method. It is anatomically more direct; it does not inflict a double wound in the bladder, and does not open the prevesical cellular tissue. The whole operation can be performed deliberately, under the direct guidance of sight as well as touch; it permits the operator to remove as much or as little of the prostatic overgrowth as is desirable or feasible. The drainage of the bladder and subsequent wound treatment are much facilitated by the dependent opening. The writer calls attention to the conspicuous merit of Proust's operation. By this method, the bladder and prostate can be easily and safely opened from the perineum either for exploration, for removal of calculi, or for removal of the whole or parts of the prostate.

British Medical Journal, May 28, 1904.

A Method of Arresting an Epileptic Fit.—J. C. McConaghey turns the patient on to the left side as soon as the fit begins, and holds him in this position, nearly all the recorded cases were treated in the "tonic spasm" of the fit, and in most cases the muscles all became flaccid, and the color of the face improved, and no "clonic spasm" supervened. The method is very simple. The writer then notes a case showing the efficacy of tying a ligature round the limb from which a "sensory aura" takes its origin.

Leishmania Donovani in the Soudan.—Sheffield Neave reports this case of a boy of about eight or nine years. He came to be treated for chronic diarrhœa, and had recovered from this, but had a daily rise of temperature, usually remitting to normal, and commonly rising to 101° at night. His spleen extended down to the level of the navel, but well to the left of it. A blood count showed erythrocytes, 4,200,000; leucocytes, 3,000; the large mononuclears were estimated at 67 per cent. The boy's spleen had begun to enlarge while he was being suckled, but never gave any trouble. The cerebrospinal fluid was sterile. The urine was negative. The individual units, when separate, appear somewhat oval in form, and contain a nucleus, and a small rod-like body. They vary, apparently, in size.

Note on the Occurrence of Leishman-Donovan Bodies in "Cachexial Fevers," Including Kala-azar.—Leonard Rogers has done very careful work in the investigation of these bodies. He has been trying to learn how to differentiate the cases with the new bodies from chronic malarial fevers. He gives a table of comparison between fevers showing Leishman-Donovan bodies, and those showing malarial parasites. There is no point of marked difference between the two series. On the whole, it appears to be more likely that these bodies are a new form of protozoa very closely allied to the malarial parasites, and producing a very similar train of symptoms, but with a greater tendency to bring about a cachexial state very rapidly, and a greater resistance to the action of quinine in small doses. These parasites are to be found in kala-azar, and should they prove to be the actual cause of the disease, the matter will be one of great practical importance.

Deutsche medisinische Wochenschrift, May 19, 1904.

The Relations between Leucoplakia and Syphilis.—W. Lublinski discusses the almost diametrically opposite views entertained in regard to these conditions, and believes that some light may be gained by a closer insight into the pathology of leucoplasia. From his personal experience he believes that the latter is not a disease *sui generis*, but the localized expression of the reaction of the mucous membrane to long-continued irritation, which finally assumes the form of a white mucous patch. The principal irritants are tobacco and alcohol, and this seems partially confirmed by the fact that the disease affects men almost exclusively, and particularly at that age when these substances are being used. He is inclined to agree with the French authors, and conclude that syphilis is a disease which predisposes to the production of a leucoplakia. It should be noted, however, that syphilis itself may produce a papule or a gumma on the mucous membrane, but never a patch of leucoplakia. The latter only appears after some form of long-continued irritation has produced a reaction and may be designated as a parasyphilitic infection. Antisyphilitic treatment will be found to have no effect whatever on the improvement of the lesions; moreover, the already irritated mucosa becomes the seat of fresh irruptions, which for reasons not yet known, not uncommonly undergo malignant changes.

Mode of Action of Antitoxins in the Living Organism.—Wassermann and Bruck have attempted to show in the living organism, what has already been demonstrated in test-tube experiments, that the antitoxin merely unites with the toxin, but does not destroy the latter. If this view is correct, then when the combination present in the animal's body is broken up, the toxic action should be restored even in the presence of the antitoxin, and the animal again made ill. This the authors were able to do with tetanus. It is known that the paths of absorption of the tetanus toxin and antitoxin differ—the toxin being taken up by the peripheral nerve-endings, the antitoxin by the blood and lymph channels. The absorption of the antitoxin may therefore be interfered with by cutting out these channels, and this was done by applying suprarenin at the seat of injection, and thus bringing about a contraction of the capillaries. Mixtures of toxin and antitoxin so adjusted that they failed to produce symptoms resulted in typical fatal tetanus in those animals in which the suprarenin had been applied. This also shows that the avidity of the toxin for the nervous system is greater than its avidity for antitoxin. If not less than two hours be allowed to elapse after the injection of the neutralized mixture of toxin and antitoxin before the suprarenin is applied, the union between the two has become fixed and a separation no longer takes place and the animal remains well. If there is an overabundance of antitoxin in the mixture, the fixed union comes about even sooner—fifteen minutes. The action between the two substances seems therefore to be a chemical one—the antitoxin unites with the toxin and prevents the latter from attacking and causing disease in living animal cells.

Is the Syphilitic Virus Capable of Being Filtered?—Klingmüller and Baermann have made some practical experiments on their own persons in order to arrive at a definite conclusion in this matter. Excised chancres or moist condylomata were rubbed up with salt solution and sand and then passed through a Berkefeld filter which

had been carefully tested and found to be impermeable to germs of chicken cholera. This material was prepared on four different occasions, and each of the experimenters received some by injection or inoculation in either arms or legs. A local inflammatory reaction followed which subsided in a short time, but nothing characteristic of either primary or secondary syphilitic lesions. The authors eliminated all sources of error and are convinced that they brought forward sufficient evidence that syphilitic virus does not admit of filtration.

Münchener medizinische Wochenschrift, May 17, 1904.

Intestinal Conditions Associated with Achylia Gastrica.—Tabora expresses some doubt of the truth of the explanation which has been advanced by Opler, Ewald, Boas, and others to account for the diarrhœal disturbances associated with insufficient gastric digestion. It has been generally assumed that the condition is due to incomplete preliminary digestion with lack of power to bring about peristalsis. The partially digested food materials undergo decomposition, and in addition are the cause of secondary catarrhal manifestations. From observations on a large number of cases in Riedel's clinic, the author found that the diarrhœal symptoms were only present in about 20 per cent. of the patients, and does not believe that they can be entirely attributed to secretory disturbances. He claims that increased intestinal decomposition is the primary factor, and that this form of diarrhœa may be classed as a fermentative dyspepsia, in which increased carbohydrate fermentation forms the basis of the irritation He arrived at this conclusion in the following manner: persons with an achylia gastrica, and also controls with a normal secretion, were fed increasing amounts of albuminous materials, and the quantity absorbed and that decomposed carefully measured, the latter by determining the ethereal sulphates, the indican in the urine and the indol in the fæces. It was regularly found that with achylia, the degree of indol decomposition became markedly increased with the increased amounts of albumin administered. After a few days of this, a diarrhœa came on. In the control cases, such changes were not observed. The maximum excretion of indican in the urine was present at the same time as the maximum excretion of nitrogen, and sometimes even before this, while in the controls the increased indican excretion was not found until a considerably later period. By way of treatment he recommends a restricted diet of albuminoids, and the very free administration of carbohydrates. An exclusive milk diet has also been found very efficient.

The Treatment of Menière's Disease.—O. Veraguth reports two cases of aggravated Menière's disease in which good results were obtained by the application of the galvanic current. In the one the condition was undoubtedly brought about by specific changes in the middle ear; in the other, a neurasthenic individual, by an old chronic otitis media. In both of these dietetic and symptomatic treatment was instituted, but the main effects were seen to follow the galvanization of the acoustic nerve, and consisted of an early amelioration of the attacks. The cathode was placed on the back of the neck, the anode over the ear, and a current varying from ½ to 1½ milliamperes was employed for three minutes daily. It was also used with the cathode applied over the other ear. It was found that the patients were very sensitive to changes in the current, either when reversed or increased.

The Production of Tuberculosis.—Volland claims that the infection with tuberculosis occurs most often as the result of a previous scrofula. This is brought about during the period of dentition when the epithelium of the mouth is softened by excessive salivation, and also when, as a result of free nasal secretion, the outer skin has become irritated and itches. The child proceeds to relieve the latter by rubbing the area with its hands which are liable to contain the tuberculous virus. Absorption readily takes place by the blood and lymph channels. The author thinks that in order to mitigate the tuberculosis evil, it is necessary to protect the child against the infection, Among the prophylactic measures recommended, the most important is to keep the child's hands as clean as possible. He suggests that certain precautions be taken with children, which include prohibiting the child or infant from crawling around on the floor, and when teaching them to walk to hold them up by the hands, or using a proper appliance. When the child has fallen the hands should immediately be cleansed of all dry dust. Toys should also be frequently cleaned. Drooling saliva and nasal secretions should be carefully wiped away. The training of nurses should not be limited to their care of small infants, but should be extended so as to include that of children after the second year, and the cleanliness of children's hands be especially insisted on. The youngsters should also be instructed as soon as possible to avoid having dirty hands.

Berliner klinische Wochenschrift, May 16, 1904.

The Union of Diphtheria Toxin and Antitoxin.—J. Morgenroth contributes a review of recent work which has been done to establish a knowledge of the processes which take place in the union between diphtheria toxin and its specific antitoxin. This has been done for the purpose of supporting Ehrlich's theory of the complex constitution of the diphtheria toxin and the existence of toxones as disputed by Arrhenius and Madsen. The details of the author's experiments are not suitable for abstracting. By injecting mixtures of toxin and antitoxin he obtained results which convinced him that the paralyses which followed the injections could not be explained by the action of the toxins present, but that it is necessary to attribute the effects in part to the toxones. It was also found that the free paralyzing element is not subjected to resorption without hindrance, as believed to be the case by Madsen, but that a well marked reaction takes place immediately. The results obtained from these experiments leads the writer to claim that the toxones as defined by Ehrlich, really exist, and that the phenomena observed cannot be explained unless their existence is acknowledged.

Hernia in Laparotomy Scars.—M. Sperling reports two cases which he believes may be of value in serving as a warning in calling renewed attention to the necessity of avoiding this condition. In both of these patients a supravaginal amputation of the uterus had been done. In one case suppuration took place in the abdominal wall, the other healed by primary union. Herniæ through the scar followed in both. Four years after the operation in one patient, and seven years after in the other, a carcinoma developed in the thin-walled hernial sac. It was tightly adherent to a large intestinal convolution and a portion of the greater omentum. Radical operation was found to be impossible. The author is inclined to believe that the production of the carcinoma may be attributed to the irritation caused by a belt which the patients had worn to retain the hernia. In addition to this he thinks that the buried peritoneal sutures did not result in accurate approximation of the edges and so produced irregularities in the hernial sac, with subsequent intestinal adhesions. He has therefore modified the method of closing the abdominal wall by omitting the suturing of the peritoneal edges, and passes several interrupted sutures through all the layers, about 2-3 cm. away from the wound margin. These are tied after the fascia has been carefully united with fine, interrupted silk sutures. Where the abdominal wall is thick, he lays a strip of iodoform gauze on the fascia and lets it project from both ends of the wound.

A Case of Fungoid Mycosis.—Ernesto Bozzi writes on this subject, illustrating it with a case observed by him. It is a grave disease, chronic in its course, and always fatal. There may be changes in the composition of the blood. Kaposi has grouped such cases under the name of sarcoid, a generic name, but which denotes its malignity and the characters which it presents. The diagnosis is not always easy. The blood changes may be absent or late in their occurrence. Alibert named it; Bazin gave its clinical course; Ranvier studied it histologically. The patient was a sea captain, fifty years of age. Eight years before the case was observed by the author, he began to suffer with articular rheumatism. About that time he began to notice a spot on the abdomen, which gave no pain and soon disappeared. Four years after, while taking a Turkish bath, he noticed a pronounced itching in a similar plaque in the upper right hypochondrium. Here the skin became thickened and fissured with increased itching. Similar patches formed and disappeared at times. Iodide of potassium and bichloride of mercury had no effect on the disease. The glands along the pectoral muscle now became enlarged. An operation was done to remove the ulcerated patch, which did not return. The blood examination now showed 4,750,000 red blood cells, and 5,850 white blood cells to the cubic millimeter. The general condition of the patient continued to be excellent and he kept at his work. The axillary glands next became enlarged, so much so as to interfere with the deep circulation of the arm. These were later removed and did not return. The pectoral glands enlarged on both sides, and were treated by injections of Fowler's solution, with decided reduction in size. A few months later he suddenly began to fail in health, lose strength and become cachectic. Stomach symptoms supervened, vomiting, diarrhœa and emaciation, ending in death from cardiac paralysis. Pain in the abdomen was found to be connected with a swelling the size of an orange, between the spleen and the kidney. The examination of the first part removed showed it to be of fibrous consistence, with many small, round, mononucleated cells, having a small amount of protoplasm, finely granular. Blood vessels were scarce and degenerated. The structure was characteristic of fungoid micosis. Had it been a sarcoma it would have been fatal more quickly.—*Il Policlinico*, March, 1904.

MANUEL DE PATHOLOGIE GÉNÉRALE ET DE DIAGNOSTIC. Par le Dr. LÉON MOYNAC (de Bayonne), Ancien Interne des Hôpitaux de Paris, Ancien Professeur libre de Pathologie et de Clinique. Sixième Edition, revue et considérablement augmentée par Constant Hillemand, Ancein Interne des Hôpitaux de Paris, Lauréat de la Faculté. Tome Premier, Paris. G. Steinheil, 1903.

THE text of these volumes is arranged in sections and the sections are subdivided into chapters. The writer gives first certain definitions and general preliminary remarks on the subject under consideration. The first section is devoted to etiology, the subdivisions of which are, extrinsic causes, and intrinsic causes. Under the first heading the writer discusses mechanical, physical, chemical, biological, and social causes.

Perhaps the most interesting part of this section is that devoted to biology. So much attention has lately been given to the effects of venom on the human organism that a further contribution to this subject by writers with the experience of Moynac and Hillemand will receive the attention of all those interested in this branch of medicine. The larger part of the section, however, is devoted to the consideration of the vegetable organisms, including those microorganisms pathogenic to man. Under pathogeny and pathological physiology, the subjects of the next section, the rôle of the nervous system is treated from these points of view.

Gangrene, wounds, dropsy, degenerations, hemorrhages, congestion, fever, abscesses, inflammation, the action of cold and heat on the human economy, all have a place under the section devoted to morbid processes. Tumors of various kinds, both malignant and benign, are considered from various standpoints.

The general subject of the second volume is semiology. There is no part of medicine that is of more timely interest than this, which among many other themes, includes the examination of the blood and cardiovascular apparatus, the examination of the urine and of the genitourinary organs. The concluding chapter considers disease from a general view-point, the evolution, prognosis, and treatment of disease, not the least interesting of which are the parts dealing with organotherapy and serotherapy. This manual considers such a variety of subjects that it can scarcely fail to be of interest to physicians in general.

DISINFECTION AND THE PRESERVATION OF FOOD, together with an Account of the Chemical Substances Used as Antiseptics and Preservatives. By SAMUEL RIDEAL, D.Sc. (London), Fellow of University College, London; Fellow of the Institute of Chemistry; of the Chemical Society and of the Sanitary Institute of Great Britain; formerly Examiner in Chemistry to the Royal College of Physicians; Lecturer on Chemistry in St. George's Hospital Medical School; and Public Analyst for the Lewisham District Board of Works, etc.; Author of "Water and Its Purification"; Sewage and the Bacterial Purification of Sewage"; London: The Sanitary Publishing Co., Limited; New York: John Wiley Sons, 1903.

THE subject of disinfection in its various aspects is of such general interest that a book, especially by one who is so well fitted to write on this subject as the author of this volume is, is heartily welcome, in its new edition. All of the more important historical parts of the older work have been retained in the new edition which has been entirely reprinted. Some of the earlier matter has been excised while other parts have been condensed. In the present volume the writer gives the results of many researches which he has conducted since the appearance of the last edition. The section of food preservation has been enlarged so that the manual cannot fail to be of practical value to those engaged in many trades and industries. The writer believes it impossible under the modern conditions of life to do without some methods of preserving perishable foods without great loss, and he even believes that in some instances, with proper safeguards, that chemical treatment may be desirable. The details of these methods are carefully considered.

LES MALADIES DE LA NUTRITION. LES MALADIES DE L'ESTOMAC. Par ALBERT ROBIN. Second edition. Paris: J. Ruff, 1904.

THE present work of this well-known French clinician is written in a remarkably clear style. The functions of the stomach are minutely discussed, and form the basis for recognition of diseases. Robin divides the diseases of the stomach into the three following groups which can be clinically recognized: (1) Dyspepsia with exaggerated functions, or hypersthenic dyspepsias; (2) Dyspepsia with diminished functions, or hyposthenic dyspepsias; (3) Dyspepsias with pervert functions, or "gastric fermentation." The therapeusis is thoroughly discussed and forms a preëminent part of the book. We do not hesitate to highly recommend this work on the stomach to our readers.

GOLDEN RULES OF DENTAL SURGERY. By CHAS. W. GLASSINGTON, M.R.C.S., L.D.S.Ed., Senior Dental Surgeon to the Westminster Hospital, Lecturer on Dental Materia Medica and Therapeutics (late Dental Surgeon) to the National Dental Hospital and College, etc. "Golden Rule" Series No. XIII. Bristol: John Wright & Co.; London: Simpkin, Marshall, Hamilton, Kent & Co., Ltd., 1904.

THE author of this tiny booklet has compressed many valuable suggestions into small space. The "Golden Rules" are given as the result of an experience of twenty-five years.

A TEXTBOOK OF PRACTICAL GYNECOLOGY FOR PRACTITIONERS AND STUDENTS. By D. TOD GILLIAM, M.D., Professor of Genecology in Starling Medical College, Columbus, Ohio; Gynecologist to St. Anthony and St. Francis Hospitals, Columbus, Ohio; Fellow of the American Association of Obstetricians and Gynecologists; Member of the American Medical Association, of the Ninth International Medical Congress, and of the Pan-American Medical Congress; Honorary Member of the Northwestern Medical Association; Consulting Gynecologist to Park View Sanitarium, etc. Illustrated with 350 Engravings, a Colored Frontispiece, and seven Full-Page, Half-Tone Plates. Philadelphia: F. A. Davis Company, 1903.

THIS volume contains over 600 pages, and is a very comprehensive treatise on the subject of gynecology with all that it includes. The book is divided into fifty chapters, as nearly uniform in length as possible, in order to correspond to the number of lectures and recitations generally devoted to the subject in a collegiate term. The writer considers first the general causes of diseases of women—the various social states and their effects; physics and physiology as applied to gynecology; dress; and muscular exercise. Then follow chapters on gynecological examination and technique, including case-book, preparation of the patient, methods of examination, postures, preparation for operation, the operating room, instruments, etc. Disorders of menstruation, malformations of the genital tract, and sterility are then discussed. Diseases of the vulva and vagina, injuries to the pelvic floor with their sequelæ, and genital fistulæ follow in order. The rest of the book is given up to the consideration of the genitourinary systems. Displacements of the uterus and its appendages, inflammations, malignant disease, with the treatment appropriate to these conditions form the subject matter of several chapters. Finally, the author devotes some space to the consideration of the urethra, bladder, kidneys, and rectum, with the various disorders and diseases to which they are liable, and a description of the operations for these affections. The volume is profusely illustrated with 350 engravings. There are besides seven full-page half-tone plates. An excellent index is appended. The book is a notable addition to gynecological literature.

THE MAN WHO PLEASES AND THE WOMAN WHO CHARMS. By JOHN A. CONE. New York: Hinds & Noble, 1904.

THE subjects treated in this clever little volume are of general interest. The writer emphasizes throughout the book what he mentions in the preface—"Courtesy is not the least of the Christian virtues and it should be studied as an art." The book teems with hints of how to be tact ful and agreeable in the various walks of life.

A SHORT PRACTICE OF GYNECOLOGY. By HENRY JELLETT, B.A., M.D., B.Ch., B.A.O. (Dublin University), F.R.C.P.I., L.M.; ex-Assistant Master, Rotunda Hospital; Extern Examiner in Midwifery and Gynecology, Royal University of Ireland. Second Edition, revised and enlarged, with 223 Illustrations. London: J. & A. Churchill, 1903.

THIS field of literature is already so overcrowded that it is only a noteworthy book like the one under consideration that can call forth any interest. The majority of physicians are so well acquainted with the first edition of this work, however, that they will welcome the appearance of the revised edition. This book is treated in such a masterly manner that a great amount of information has been compressed within its covers. Naturally in a book of this size, 398 pages, it is impossible to review the numerous theories concerning the modes of treatment, and operations in gynecology which are accepted at the present day. The author therefore has set forth only those which he believes to rest upon the surest foundation and to be accepted by the best recognized authorities. The teaching of the book represents essentially the methods in use ta the Rotunda Hospital. In this new edition not only has the text been enlarged, but a considerable number of new illustrations have been added. These contribute much to the clearness of the text and to the attractiveness of the book. The subheads placed at the beginning of each chapter make the book a most convenient one for reference.

Society Reports.

AMERICAN MEDICAL ASSOCIATION.

Fifty-fifth Annual Meeting, Held in Atlantic City, N. J., June 7, 8, 9, and 10, 1904.

(Special Report to the MEDICAL RECORD.)

HOUSE OF DELEGATES.

First Day—Monday, June 6.

PRESIDENT DR. FRANK BILLINGS OF CHICAGO.

The President's Address.—Dr. FRANK BILLINGS of Chicago said that he had not expected to preside again but was in the chair because of the resolution which had been passed to the effect that the retiring president should officiate until Tuesday noon, when the incoming president should assume the duties of his office. The last meeting of the House of Delegates had been marked by cordiality, by the amount of business that had been transacted and by the facility with which the work had been dispatched. Perhaps they had been too precipitous, though he would not alter anything they had done. It was sometimes very easy to legislate and very difficult to remove legislative work. They had been safeguarded by the business committee, but this committee had been overworked, and he suggested that in place of the business committee a number of reference committees be appointed. This suggestion was acted upon.

Report of Secretary.—Dr. GEORGE H. SIMMONS of Chicago reported that the membership in June, 1903, was 13,545, 2,413 new members had been added during the past year and 919 had been dropped on account of death, non-payment of dues, etc. The membership of May 1, 1904, was 15,039. The total membership of the State societies was about 44,360. There were about 232 physicians in the service of the Pension Department and the Indian Agencies who were eligible for membership but who were so situated that there were no organizations with which they could affiliate.

The Rush Monument Fund.—Dr. JAMES C. WILSON gave an itemized account of the finances of this committee, which showed that they had at present $15,969.

Report of Committee on Medical Education.—Dr. ARTHUR D. BEVAN of Chicago, in the course of his report, said that owing to the nature of our government we could expect no help from that source in raising the standard of medical education, but must depend entirely on the efforts of a well-organized association.

The Association and Senn Medals.—Dr. LEWIS S. MCMURTRY of Louisville, Ky., reported that after having printed in all the medical periodicals the conditions for competition for this prize, and after having given physicians the opportunity to choose their own subjects or to take a subject selected by the committee, only one paper had been received, and that was not of sufficient merit to permit of the award of the prize. After discussing this matter it was decided to abolish the prize and to discharge the committee. The committee on the Senn Medal had received no papers; the House decided to let the medal stand for competition, as it was costing the association nothing.

Revision of the Constitution and By-laws.—Dr. J. N. MCCORMACK of Bowling Green, Ky., submitted a revised constitution and by-laws of the American Medical Association to the House of Delegates for adoption. Final action was, however, deferred until a future meeting.

Medical Legislation.—Dr. C. A. L. REED of Cincinnati, Ohio, reported that they had arranged to have a correspondent in every county in the United States. They had succeeded in getting 1,940 such correspondents, and had issued commissions to each, urging them to use all means in their power, both political and personal, to secure such legislation as the association should desire. They had made an effort to secure the appointment of a physician on the Panama Canal Commission, and though they had failed to get the desired appointment the general response from the members of the association was most encouraging. They had secured the passage of the bill giving the Marine and Navy Hospitals nurses and dentists. Their request that a representative of the medical corps be detailed to serve on the General Staff of the Army had been granted. They urged that the entire profession make an effort to have physicians nominated and elected to Congress as the lack of such representation was the most serious obstacle encountered in their efforts in behalf of the public welfare and the profession itself.

The Report of Provisional Committee on the Establishment of a National Bureau of Medicines and Foods.—Dr. E. ELIOT HARRIS of New York reported that the five members of his committee had labored with five members appointed from the Pharmaceutical Association and had conferred with the Bureau of Agriculture of the United States. They could hope for nothing from the United States Government that the two national societies could best do the work. The drugs and foodstuffs could be referred to the Department of Agriculture for analysis or to a laboratory under the direction of the American Medical Association and the American Pharmaceutical Association. Such a bureau would be a separate entity, and while composed of members of both associations neither association would be responsible legally. The practicability of this plan could only be decided by actual trial. He recommended that five members should be elected to confer with five members from the Pharmaceutical Association, that they should act as a distinct body and that permanent directors should be appointed.

Report of Committee on National Incorporation.—Dr. JOSEPH D. BRYANT reported that they had been fortunate in securing the advice of the best legal talent, and as a result it appeared that no legal obstacle was interposed to securing actual incorporation under act of Congress of of the American Medical Association. The proposed special congressional charter was drawn up and presented to the House for approval.

The Committee on Organization.—Dr. J. N. MCCORMACK said in his report that great progress in organization had been made. Out of the 2,830 counties in the United States, 1,600 were more or less completely organized.

The Sections and Section Work.—Dr. L. S. MCMURTRY of Louisville, Ky., reported that the heads of the various sections had met and mapped out the work and systematized it so that the work of the sections no longer overlapped, and that every effort was being made to raise the standard of the scientific work.

Second Day—Tuesday, June 7.

Dr. J. B. ROBERTS of Pennsylvania called the meeting to order.

Committee on National Incorporation.—This committee presented the following resolutions: (1) That the Board of Trustees be empowered to make the present charter correspond with the changes in constitution and by-laws. (2) That the Board of Trustees should endeavor to secure from Congress a suitable and desirable national charter.

Adoption of the New Constitution and By-laws.—The new constitution and by-laws as presented at a former meeting were adopted after a few insignificant alterations and additions had been made.

Report of the Board of Trustees.—This report contained an extensive and detailed account of the finances of the association. It showed that the association owned real estate valued at over $100,000, and that they had other investments in more convertible securities, to the amount of $40,000, which almost provided for the Reserve Fund of $150,000, which the association desired should be set

aside for use in emergency before any change should be made in its fiscal policy. This fund, however, was not to be made up at the expense of the *Journal*, that was, by curtailing in any way that would effect its ideals. This report also showed that the average weekly circulation of the *Journal of the American Medical Association* was 28,615 copies weekly, which indicated an increase of 3 615 copies for the past year. The appropriation of $500 for the Rush Monument Fund was ready for the committee when needed. The treasurer, Henry P. Newman of Chicago, who had held this position for the past ten years, relinquished the funds in his possession and tendered his resignation. In February, 1903, Dr. J. N. McCormack was appointed national organizer. Nearly every State has accepted the plan of organization proposed and was complying with every requirement of the constitution and by-laws adopted at St. Paul in 1901. The work has been so completely done that it can now be left in the hands of the several State associations to complete by organizing a county society in every county in each State and territory in the Union.

Report of Committee on Branch Associations.—Dr. J. N. McCormack, to whom was assigned the duty of reporting on the advisability of dividing the country into branch associations, begged leave to recommend that permission be given for the creation of seven branches at the discretion of the governing authorities of the State associations composing them, and so arranged as to cover the entire country. A provisional division was made and a form of constitution and by-laws was submitted, under which the presidents of the respective State associations become vice-presidents of the branch associations, and the presidents of these larger bodies in turn become the vice-presidents of this association. It was also provided that membership in the branch associations should be voluntary. It was recommended that the branch associations hold their meetings at the same time with that of the State associations of the jurisdiction in which the meeting is held. Instructions were given at the last meeting to the Committee on Organization to confer with the governing authorities of the various State associations and to formulate some general plan for holding the annual meeting of these bodies in the fall, or at a time which would least conflict with the attendance of members at the sessions of the association, and in pursuance of this it was recommended that all State associations hold their annual meetings during the fall and during the winter months.

Third Day—Wednesday, June 8.

Committee on Organization.—Dr. J. N. McCormack's plan for the formation of seven branches with met considerable opposition and after much discussion was referred to the committee on organization with instructions to obtain an expression of opinion from the various state societies and to report next year.

Section and Section Work.—Dr. Elmacher recommended that a permanent committee for this work whose experience would be effective in maintaining reforms be appointed.

Prophylaxis of Venereal Diseases.—Dr. Henry D. Holden of Brattleboro, Vt., said that since the attention of the profession and the public had been drawn to the fact that effects of venereal disease upon public health and social and moral conditions was as far reaching as that of alcoholism or tuberculosis the National, State and Municipal authorities would be willing to co-operate in securing legislation for the prevention of the spread of this class of diseases. At present, thirty-three States had no laws whatever on this subject except municipal ones. All the large cities were deficient in hospital accomomdations for class of patients. The Main Society had agitated the question of reporting such cases to the Board of Health. Michigan had a law forbidding the marriage of persons affected with this class of diseases and fixing a fine of from $500 to $1,000 for its violation. In these cases a physician who had attended such parties was compelled to testify. The influence of the Association in assisting the study of venereal diseases and in securing legislation for the prevention of their dissemination was urged.

Scientific Work.—Dr. Alfred Stengel of Philadelphia reported that the Association was contributing funds to several members for the purpose of carrying on promising researches and that some satisfactory results had been obtained.

Dr. H. Woods of Baltimore recommended that recognizing the deleterious effects of wood alcohol and liquors containing it, the federal authorities be invoked to designate the substance a poison and to formulate regulations regarding its sale.

Dr. E. E. Harris of New York requested that as the New York Association and Society had affiliated, members be allowed to register as guests of the Association.

It was resolved that the Association endorse the action of the Postmaster-General in regard to the use of mails for the distribution of quack medicines and appliances, obscene lierature, etc.

GENERAL SESSION.

First Day—Tuesday, June 7.

Rev. Wm. Aikman of Atlantic City opened the meeting with prayer.

The Hon. Franklin P. Stoy, Mayor of Atlantic City, welcomed the American Medical Association to the city, and formally presented the assembly with the freedom of the city. He said that he had had the privilege of welcoming them four years ago and hoped that he might again have the privilege when they next returned, as the association was always welcome to Atlantic City.

Dr. Theodore N. Reed of Atlantic City welcomed the visiting association on behalf of the local profession.

Dr. G. C. Savage of Nashville, Tenn., the first vice-president, responded to the addresses of welcome on behalf of the association. He called special attention to the fact that the American Medical Association of to-day was a very different and a much more powerful body than that of four years ago, and took this occasion to give Dr. McCormack credit due him for this advance in organization.

The Major Walter Reed Monument.—Dr. W. W. Keen of Philadelphia informed the association that the committee of which he was chairman had been incorporated in the District of Columbia and was thoroughly equipped to take care of any funds that might be raised for the purpose of creating a memorial to Major Walter Reed. After referring to Major Reed's services to humanity, he asked that the association contribute $10,000 for the proposed memorial.

Dr. Wm. Welsh of Baltimore said that this was a matter which should awaken the enthusiasm of the association, as Major Reed's discovery was one of the first magnitude, greater than any other that has been made in this country. He had practically eliminated yellow fever from the Island of Cuba and from other sections of the West Indies and South America. The yellow fever epidemic of 1888 had cost over $1,000,000, so that aside from the saving of human life the commercial value of his work was untold. He hoped that the association would respond to the demands of the committee without further urging.

The California State Society subscribed $500 to the fund, and a number of physicians subscribed $1,000, so that at the close of the meeting Dr. Keen announced that $7,500 had been subscribed and he hoped to raise the remaining $2,500 before Friday.

The retiring president, Dr. Frank Billings, then introduced the president-elect, John H. Musser of Philadelphia.

Some Aspects of Medical Education.—This was the title of the President's Address by Dr. JOHN H. MUSSER of Philadelphia. He congratulated those present that they were on the eve of a union of all members of the profession in one harmonious organization. Thirty-four states had adopted the uniform plan of organization and membership in the reorganized states had increased 400 per cent. Reference was made to the deaths during the past year of Mac Lean, Hibbard, Johnson, Love, Engelmann, Gaston, de Schweinitz, Pearce, and others.

The past two years, he said, had shown that great responsibilities rest on the House of Delegates. The delegates had, however, nobly responded to the trust confided to them, as was shown in the more prompt transaction of business and a gain in time for purely scientific purposes.

In regard to the section work in the association the President recommended that the secretaries of the various sections should be continued in office for a term of years and that the work of the sections should be done in collaboration so that one topic might be exhaustively considered at the meetings of the association without repetition in other sections. The association should be divided into two main sections for work in the mornings, that of (*a*) *Medicine*, including pathology, diseases of children, nervous and mental diseases, materia medica, stomatology, cutaneous medicine, and sanitary science; and (*b*) *Surgery*, including obstetrics, gynecology, and the more closely related surgical specialties. The sections should take up and organize special international congresses when the time was ripe for such meetings, and finally each section should name to the President a list of its members, from which he could select, when asked, delegates to important national meetings of international congresses. Dr. Musser believed that the section on Sanitary science should receive greater support from the organization. Greater attention also should be paid to the scientific exhibit. When a section took up a subject not only should its clinical, pathological, and therapeutic aspects be discussed, but the bibliographical and historical features should be brought out. The fostering influence of the members of the association should also be given to the recently formed association of Librarians. Allusion was made to the dedication of the Rush monument. The association was to be congratulated on the completion of this tribute in perpetual bronze to one of the most distinguished of our countrymen.

Special attention was called to the subject of medical education. In fact the main object of the association, the arator said, was specified to be the elevation of the standard in this respect. In most respects it seemed now definitely settled as to the course of education a candidate for the degree of medicine shall take. Questions of pedagogy were still debatable, but the student who wished the quickest returns, the most lasting remuneration, perennial stimulation of the intellect, and continuous enjoyment in the pursuit of his labors should take a college course of three or four years, a four years course in medicine, and if possible a hospital interne-ship. The essential of success in any department of medicine was diagnostic ability which required powers of intellectual penetration and discrimination. Mathematics was reasoning and study of languages was interpretation; history was the interpretation of life. These three promoted scholarship and cultivated thought. To be a thinker was the salvation of the physician. There should be one educational requirement—the equivalent of that for which a first-class college degree stands, whether received at a high school or university.

The complaints of the public against half-educated physicians were due not alone to the medical school with its deficiencies, but partly to the public itself, particularly that portion of it acting on the boards of trustees of various hospitals which were unwilling to admit students to the wards for purposes of instruction. It was manifestly impossible for the medical schools to educate all their students properly. There must be a freer interchange of facilities between the colleges and hospitals. The latter gave every chance to a nurse to fit herself for the care of the sick under the doctor's direction, yet they refused to give corresponding facilities to those who were to command the nurse.

Finally the speaker urged that every doctor should take his sabbatical year. Money spent in well-earned recreation would prove a most valuable investment

A halt from time to time was necessary also to give opportunity for review, for sweeping out and refurnishing the mental storehouse, and for "jacking up" the mental and moral machinery. There were few who, on stopping to think, would not find in themselves an unconscious tendency to slight their work, so become slipshod, and hurry over matters. This was partly in evidence of overwork, but its cure lay in the post-graduate school; no obstacle could withstand the continuity of drill.

He then spoke of the very general neglect on the part of physicians to perform autopsies. A man who had met with unusual symptoms in a case, or who had been unable to arrive at a satisfactory diagnosis, was wrong not to secure a post-mortem examination if death occurred.

In conclusion, Dr. Musser said: "We rejoice together and cherish our history, by the warp and woof of which we are woven to the past. What heritage for us and our children! Dead must be the soul that wearies of communion with the spirits of the past; deep must be its slumber on which falls the thought of centuries; lethargic its actives that are aroused not by the deeds of heroic men! Honor and fortune exist to him who always recognizes the neighborhood of the great, always feels himself in the presence of high causes. We worship together our science, devotion to which brings forth character, smothers egotism, levels pretension, drives out solitude, develops such loftiness of thought which can see that against all appearances the nature of things works for truth and right forever.' Of our art, let us see to it that when the final summons comes it can be said of us 'Greater love hath no man than this, that a man lay down his life for his friends."'

Oration on Medicine.—Dr. GEO. DOCK of Ann Arbor, Mich., delivered this oration. (See page 949.)

Symposium.—"Institutions Doing Research Work for the Science of Medicine"

The Carnegie Institution.—Dr. JOHN S. BILLINGS of New York said that Andrew Carnegie had given $10,000,000 for the purpose of founding an institution for research, the general object of which should be to increase and diffuse knowledge. Part of the funds have been set aside for buildings, while $300,000 was allowed for annual expenses. The persons interested in the association had spent one year in studying what lines of work would be the most desirable. The two objects were to promote individual research and to find exceptional men. In biology the subject of evolution and heredity was being studied. In the physiological chemistry nutritive values of food were being investigated as well as the action of some drugs. About $10,000 had been contributed to the index medicus. It was not the object of the institution to undertake work that would likely be done by other institutions, or such work as promised to be of commercial value. They endeavored to find the exceptional man, and to that end amounts from $900 to $1,500 were allowed to some twenty-five men who might prove to be exceptional each year.

The Rockefeller Institute.—Dr. L. EMMET HOLT of New York said that the story of the discovery of the diphtheria antitoxin had interested Mr. Rockefeller, and he thought that such work could be done in this country, that the ability was here if the opportunity could be provided. The institute was incorporated in 1901, having as its object the study of the causes, prevention and treatment of disease. At first a number of fellowships were given

out in existing laboratories, but centralization seemed necessary, and a gift of $1,000,000 from Mr. Rockefeller made possible the purchase of a plot of ground in New York where a laboratory would so soon be constructed thoroughly equipped for work in bacteriology, pathology, physiological chemistry, and pharmacology. A small hospital would adjourn the laboratory in order that clinical advantages might be provided, and the work might be kept along the lines of practical medicine.

The Memorial Institute for Infectious Diseases.—Dr. FRANK BILLINGS of Chicago said that this institution had been founded by Mr. and Mrs. McCormack as a memorial to their son who had died of scarlet fever. While the study of scarlet fever was the chief object, all acute infectious diseases, with the exception of smallpox, would be investigated. A hospital had been incorporated and they had started with only ten beds. Last year they had received ground and money enough to build a pavilion which would contain fifty beds. The chief object of the work was to find the cause of scarlet fever and, if possible, a specific

The Harvard Research Work.—Dr. THOMPSON of Harvard reported for Dr. Ernst that there were in all fourteen departments and laboratories, ninety-one instructors and others intereseted in research work, 128 places in which such work could be carried on. The facilities and libraries of the department were extremely good, but only five departments had funds for such a purpose.

Appendicitis from the Standpoint of a Physician.—Dr. S. G. BONNEY of Denver, Col., said that the responsibility of the physician in appendicitis was far greater than that of the surgeon, because early diagnosis was a factor of supreme importance and afforded the solution of the problem as to the time of operation. There was no definite relation between symptoms or physical signs and the degree or nature of the actual pathological change within the abdomen; the latter was often a mere matter of conjecture. A report of selected illustrative cases from the author's personal experience was reported, and the paper itself was offered as a plea for greater definiteness of conviction among physicians as to the proper course of procedure in the various phases of the disease.

Suicides, with Some Illustrative Cases.—Dr. JOHN L. DAVIS of Cincinnati said that in twelve years there had been over 77,000 suicides recorded in the United States, and he believed the American strenuous life was having a disastrous effect upon the physical condition of our people, unbalancing them physically, causing feverish intensity and eagerness to excel to be responsible for such an alarmingly large number.

Dr. Wm. Pepper Laboratory of Clinical Medicine.—Dr. ALFRED STENGEL, of Philadelphia said that the object of William Pepper in founding this institution was to establish a bond between purely scientific and essentially practical work. The institution did not permit undergraduate work, but was open to any physician who might want to carry on research work and who had the necessary preliminary training. It had been in existence for about ten years, and was the first clinical laboratory founded in this country and as such had been the inspiration that had led to the establishment of a number of others.

Presentation of Presidents' Portraits.—Dr. J. R. PENNINGTON of Atlantic City stated that another portrait had been secured which Dr. Wyeth would present to the Association.

Dr. WYETH said that twenty-eight years ago the meeting had been presided over by Dr. Sims, whose portrait he now presented. Because of his friendship for Dr. Sims he preferred that another should speak of his noble character and should trace his wonderful career. The portrait was the gift of one of his children. If three men were named who had done most for humanity, their names would be William Jenner, George Washington and Marion Sims.

SURGICAL SECTION.

First Day—Tuesday, June 7, 2 p.m.

Chairman's Address.—Dr. CHARLES A. POWERS of Denver read an address in which he reviewed the history of the section, giving the names of the previous chairman and a résumé of their work. He referred to the progressive surgery in recent years and commented on the increase in the number of men who were devoting themselves exclusively to surgery. He detailed at some extent the history of surgery, and stated that he felt the younger men were inclined to overestimate the results to be gotten from surgical operations. He feared many operations were done without a due amount of previous study and considered that no one should perform an operation on any one else that he would not have allowed to be done on himself under the same circumstances. He urged that surgeons should have fine sensibilities, be courageous and hopeful, and of the highest character, with most delicate feeling.

The Danger of Allowing Warts and Moles to Remain Lest They Become Malignant, with Twenty-five Illustrative Cases.—W. W. KEEN of Philadelphia presented a communication with this title. The paper was chiefly a clinical one, intended to emphasize the danger of not removing warts and moles and sometimes nævi, because not uncommonly they became malignant. He pointed out that many of these moles and warts were congenital, or else, having arisen later, had persisted in apparent harmlessness for many years, and then, in consequence of injury, friction of the clothing, frequent scratching or other irritant, they began to increase in size, and were then already malignant. To wait until they began to grow would be waiting too long. He advocated that they should be removed with the skin in which they grow *before* any malignant change occurred—that is, during the period of quiescence. Twenty-five cases were reported, arising on almost all portions of the body. Of the twenty-five, eleven were known to have died, sometimes even in spite of multiple operations, or even amputation, and several others probably died.

Dr. WM. L. RODMAN of Philadelphia said he felt Dr. Keen had rendered a great service in calling attention to this matter, and that his experience had been very similar to the author's. He gave the details of three cases occurring in his own practice, the first making a good recovery after operation, the second doing fairly well for the present time, and the third dying within a year of the operation. The first was a case of a wart on the temple, the second a wart on the left hand, and the third an ulcer on the back of the hand following a wart.

Dr. GUSTAVE FUTTERER of Chicago referred at some length to the important part played by mechanical factors in producing malignant changes in cells. He commented on the close relation between metaplasia and carcinoma, and the fact that the former may occur in any part of the body. He had a number of specimens illustrating his points which he demonstrated to the members.

Dr. ROBERT F. WEIR of New York believed that every mole and wart had better be destroyed at once, but referred to the difficulty of getting the patient's permission to do so, largely on account of the resulting scar. He detailed his own method of dealing with these cases when an operation was refused, the principal point being the use of acetic acid.

Dr. ERNEST LAPLACE of Philadelphia considered that these cases usually occur in tissues of diminished resistance and believed old age to be a prominent predisposing factor. Warts proper, in his opinion, were of [a true epitheliomatous type, and a wart proper nothing more than a hypertrophy of the papillary layer of the skin. He made some remarks on tumors of an angiomatous

type where there was a great proliferation of the blood-vessels which were likely to take unto themselves what any other form of proliferation might do.

Dr. A. D. Bevan of Chicago feared the possibility of making a very rapid general involvement from the operation itself by apparently infecting the operative wound. He referred to cases of removal of melanotic sarcoma when the operation had been followed almost immediately by general involvement. To overcome this, he favored making the growth absolutely dry before operation by the use of the Paquelin cautery. Referring to cases in which a large number of moles were present, he showed how impossible it was to think of removing them all, but he favored early operation when any indication of irritation was present.

Dr. Keen, in closing, referred to a mole as a match which could set fire to a great conflagration. He agreed with Dr. Bevan as to the possibility of a general involvement following operation and urged the use of reason in these cases.

Operation for Malignancy in the External Carotid Area; Its Failures and Successes.—Dr. Robert H. M. Dawbarn of New York City read this paper, in which he gave a brief description of the technique of external carotid extirpation. He commented on the remarkable safety of the operation, and gave his deductions, which were drawn from an experience of more than fifty cases. He showed why there was such a short respite in carcinoma as compared with the much better record in sarcoma. He pointed out when and under what circumstances the operation was indicated and what was its probable future.

Dr. George N. Crile of Cleveland reported that he had never tried the operation, but was very anxious to learn more about it. He felt it was much better to close an artery temporarily to control hemorrhage rather than to use a permanent ligature. He feared the occurrence of embolism, which danger, although small, he considered avoidable.

Dr. Bristow claimed to have operated eleven times on six patients, five of which were epitheliomata and one sarcomata, the latter dying shortly after the second operation. He laid great stress on the fact that the patients were all very promptly relieved of their severe pain, so that their lives were made far more endurable. He reported never having lost a case on which he had operated for tuberculous glands, although in some cases sudden death followed almost immediately after the operation. In itself the operation could not cause death from hemorrhage, as it was practically a bloodless one, and he believed the cause of death to be due to nerve inhibition.

Dr. Dawbarn, in closing, agreed with Dr. Bristow on the sudden and complete cessation of pain following the operation and referred to one case in which a sufficient shrinkage took place to make an operation possible. He found it very difficult to make any estimate of mortality, but believed under ordinary circumstances that it would not be over 5 per cent. He called special attention to the fact that the operation was always done as a last resort, and it was simply a question between it and a coffin.

What Is the Proper Surgical Treatment of Suspicious Tumors of the Involuting Breast.—Dr. J. Clark Stewart, Minneapolis, urged the great necessity of acceptable procedure which would allow exposure and macroscopical as well as, if need be, microscopical examination of the suspected mass before deciding upon the extent and nature of the operative procedure to be carried out. He referred to the recorded cases, illustrating recurrences by grafting, which he said were too numerous to admit of any doubt of the practical value of this point. In referring to the technique of the exploratory operation, he commented on the several important details necessary, as follows: First, all tissues exposed to infection by the incision must subsequently be removed in case malignancy is not excluded. Second, the instruments used for the section of the tumor should be laid aside or resterilized before proceeding with the operation. Third, all lymphatic connections of the tumor should be cut or interrupted before making the tumor section. With these precautions he considered it difficult to see how grafting could occur. He discussed a paper on this subject by Dr. Abbe at considerable length and quoted from Dr. Abbe's paper, taking exception to several points contained therein. Reference was also made to the work of Dr. Bloodgood, at the Johns Hopkins Hospital, and attention was called to the difference in results obtained by Dr. Abbe and Dr. Bloodgood. Attention was called to an article on this same subject by Dr. A. G. Ellis of Philadelphia, and two illustrative cases were quoted in detail. In the author's opinion, these cases illustrated very well two conditions in which the surgeon may rightfully doubt of the diagnosis and proper operative procedure unless he was aided by properly performed exploratory procedure.

The author concluded his paper by stating: First, there was a lamentable and unnecessary difference of opinion among surgeons as to the treatment of doubtful tumors of the breast; second, all tumors of the breast in patients over forty must be considered malignant until proven benign; third, most of such tumors demanded amputation with exploration of the tumor, and a complete Halsted if there was then doubt as to benignancy; fourth, an exploratory procedure should be planned to avoid contact of cut lymphatics with any tissues left behind, and any chance of dissemination of cancer cells by pressure before the removal of the breast; fifth, *x*-ray treatment, aspiration, or any but radical treatment was objectionable as causing delay and dissemination.

Dr. Wm. Jepson of Iowa urged the free use of the microscope in these cases, owing to the symptomatology of the benign and malignant growths overlapping each other so much. He believed a large number of benign growths were really benign temporarily and that one-half of the sarcomas were cystic. He doubted if it was so essential to make a differential diagnosis simply to save a breast now and then from being removed on the supposition that it was malignant when it was benign. He considered that every growth in an involuted breast must be looked upon as being malignant in at least nine out of ten cases and ventured the belief that the day was not far distant when it would be considered good surgery to begin operative procedure by total extirpation at once in every breast that was the seat of a growth.

Dr. H. R. Wharton of Philadelphia agreed with the essayist on the question of malignant growths in the breast, and felt considerable difference should be made in the decision according to the age of the patient. In his opinion it did not matter so much after the menopause as it did before the age of thirty.

Dr. J. C. Bloodgood of Baltimore took the stand that the successful removal of tumors depended more upon an early diagnosis than upon operative technique. He gave some statistics of Dr. Halsted's work in Baltimore and claimed that the number of benign tumors of the breast was increasing because the public was seeking advice earlier. He stated that in young women under thirty with multiple tumors in one or both breasts there was no indication for operation, but in single tumors of the breast at any age an immediate investigation should be started. The danger of an exploratory incision followed by operation he did not think amounted to anything, and advised immediate exploration of a single tumor of the breast at any age.

Dr. R. H. Gibbons of Scranton agreed with Dr. Abbe's point of view as quoted by the author.

Dr. Morris of New York suggested a way of influencing patients to submit to operation by offering to remove a small part of the growth, make a frozen section diagnosis

on the spot, requiring but five minutes' time, and if benign, agreeing to simply remove the growth, while if malignant, total extirpation should be done at once. He believed that patients were usually as anxious to know definitely the nature of the neoplasm as the surgeon himself, and laid stress on the element of curiosity on the part of the patient.

Dr. WILLY MYER of New York gave a demonstration of his method of dealing with these cases.

Dr. STEWART, in closing, referred to the rule that at the Johns Hopkins Hospital only one person may examine a malignant tumor and stated that if there was so much danger from examination there certainly must be more from the use of the knife.

The Influence of the Adipose Tissue with Regard to the Pathology of the Knee-joint.—Prof. Dr. A. HOFFA of Berlin read this paper by invitation of the section and referred extensively to the work already done by surgeons in various parts of the world. He detailed the anatomical conditions found in a sound knee-joint with a special reference to the fat tissue, the character of which he dwelt upon quite fully. He reported having removed a number of growths larger than eggs, some of which showed clear evidence of hemorrhages. He advised the examination of all patients in a standing position so that both knees might be compared, and showed how different the crepitation elicited was from that of arthritis. He did not consider the diagnosis of these cases at all difficult, and while he admitted that some of his observations had been made by other surgeons they were mostly accidental, while operating for floating bodies or other disturbances of the knee-joint. He advised operation after massage, compression, etc., had been used without success, the incision preferably being on the medial side of the patella. The results of his experience had generally been very satisfactory as the disturbance caused by the growths was removed when they were extirpated and the operation was carried out with the necessary antiseptic precautions without danger.

Surgical Lesions of the Axillary Plexus.—JOHN A. WYETH, M.D., of New York reported in detail four cases of neuromata of the axillary nerve, all in women, and stated that temporary paralysis following a surgical operation was generally due to accident or inadvertence, which was largely his reason for calling the attention of the section to the subject.

Dr. JOHN B. MURPHY of Chicago, reported having known of a case of paralysis of the deltoid following an operation for appendicitis. He considered that cases of paralysis of the musculo-spiral were more rare than they used to be and regretted that some of them would not get well but would degenerate in spite of all one could do. He urged the avoidance of all extreme positions which produced pressure upon the nerves.

Dr. WALTER M. BRICKNER of New York felt that two things were to be avoided: the keeping of the arm in an extreme position for any length of time without change and the dangling of the arm at the side of the table. He believed that these paralyses were more often the fault of the anæsthetist than of the surgeon, and urged that the former's attention should frequently be called to the position of the arm.

Dr. E. W. HOLMES of Philadelphia related his experience while ligating the third part of the subclavian artery and common carotid for an aneurysm of the transverse part of the arch of the aorta. He explained anatomically how these conditions arise and how they may be overcome.

Dr. SOMMERS of Omaha referred to a surgical table in more or less general use at the present time which is provided with catches to hold the shoulders from the use of which paralysis has occasionally resulted, and urged that these supporters should be well padded before being used.

The Matas' Treatment of Aneurysm.—Dr. J. F. BINNIE of Kansas City, Mo., read this paper. He said that in 1892 Dr. Rudolph Matas presented to the American Surgical Association his classical paper on the radical cure of aneurysm. Matas' method of operating combined the advantages of ligation and excision, while at the same time it was easier, safer, and might be more conservative. The operation was suitable both to the fusiform and sacculated forms of the disease. After having applied a constrictor above the site of disease, if in the limb or temporarily ligating the proximal and distal trunks, if the carotid was the vessel at fault, one cut into the sac, thoroughly removed the contained clots, rubbed the serosa with gauze and proceeded to insert sutures. The sutures, preferably catgut, were first applied to the openings of all vessels entering or leaving the sac, then the deeper portions of the sac were closed by two rows of continuous Lembert sutures. The elastic constrictor was then removed, and if any blood escaped, one or two points of suture were inserted to control this. The next step consisted in folding the excess of sac wall on itself, and in so doing invert the edges of the skin wound. The operation, carried out as described, had been very successful, and in some cases, *e.g.* of sacculated aneurysm the circulation might be reëstablished through the repaired vessel. As Matas' operation had not yet been frequently performed, Dr. Binnie stated he deemed it the duty of those who had had even slight experience with it to publish their results; this was his excuse for the present short paper and report of a single case. J K., 52 years, laborer, fairly hard drinker, as evidenced by his statement and face; several attacks of gonorrhœa, syphilis at 37 with apparent cure under treatment, when 25 years old was confined to bed for six months with rheumatism; had had no recurrence of this, developed an inguinal hernia three years ago, and wore a truss. Two years ago he suffered from an acute pain shooting down the calf of the right leg; a tumor soon appeared in calf and had increased steadily in size; the affected calf measured 18 inches in circumference—the normal one having been 12 inches—upon examination was found expansile, pulsating tumor of the calf, reaching up into the popliteal space, which was well shown in an accompanying skiagram taken by Spaulding; there was a well-marked bruit over tumor; posterior tibial pulse was delayed; there was no tenderness and only a little pain, which was referred to the foot. Diagnosis—popliteal aneurysm.

November 10, 1903; Sisters' Hospital; chloroform; elastic constrictor applied to thigh; incision into the tumor, through the alternated gastroenemius, showed a cavity 6 x 3 inches in diameter, largely filled with a very dense lamellated fibrinous mass. This mass was removed. The aneurysm sac was thick walled and markedly atheramatous. Only one opening into the sac could be found and this was closed by catgut sutures. The whole sac was not obliterated by several layers of Lembert sutures and the superficial wound closed without being inverted. Dressings were applied and the patient returned to bed with his limb elevated before the elastic constrictor was removed. November 17—a slight elevation of temperature led me to change the dressings, when some bloody pus escaped from the wound. There was neither pain nor redness; drainage and cleanliness led to recovery; up to date there had been no recurrence. The above case was evidently one of sacculated aneurysm, efficient circulation was promptly reëstablished, but the posterior tibal in pulse can no longer be felt. The suppuration was undoubtedly due to some avoidable contamination acting on non-resistant tissues. The details of the operation were not exactly those of Matas. It seemed to me that complete closure of the sac by means of suture gave better assurance against recurrence than closure of a portion of it by two rows of sutures and obliteration of the rest by inverting the skin. The operation, in the case of popliteal aneurysm at least, was one of great ease, safety, and efficiency.

Dr. RUDOLPH MATAS of New Orleans expressed himself as much pleased with Dr. Binnie's paper and commented on the simplicity of the operation on poplitea

aneurysm. He did not believe that suppuration persisting in any case in any way conflicted with the final result and reported one similar case occurring in his own practice. The fundamental point at first was the free exposure of the sac with a minimum disturbance of the surrounding tissues, but he felt that as the cases multiplied modification would naturally arise. He believed that the restoration of the lumen was possible in many cases, as illustrated by those already reported, eight of which he was familiar with. Topographical distribution made certain modifications necessary, while aneurysm at the root of a limb required a different technique, according to his experience.

Dr. JOHN B. MURPHY of Chicago congratulated Dr. Binnie on his success and Dr. Matas on his operation. He believed that in trauma of the popliteal artery where aneurysm followed the mortality was very great. He gave a blackboard demonstration of his own modification of the operation in these cases.

Dr. H. O. PANTZER of Indianapolis reported a case of a patient who was shot through the thigh twelve years ago in whom a popliteal aneurysm developed and gave a blackboard demonstration of his methods of dealing with it.

Dr. BINNIE closed by criticising one or two of the points made by Dr. Murphy in his blackboard demonstration.

SECTION ON MEDICINE.

DR. ALEX. LAMBERT OF NEW YORK, CHAIRMAN.

First Day—Tuesday, June 7.

Chairman's Address: "The Adaptation of Pure Science to Medicine."—Dr. ALEXANDER LAMBERT of New York gave this address and said the most complete adaptation of scientific work to clinic medicine was that of Behring and others in the antitoxic sera for diphtheria and tetanus. The preventive inoculation against typhoid fever, plague and cholera was the practical application of our ideas of immunity, and the success so far obtained seemed to be that about fifty per cent. of those inoculated were protected against these diseases, and of those who acquire these diseases after being inoculated, the mortality was about fifty per cent. less than in the uninoculated. The practical value of the study of variations of blood pressure was just beginning to be recognized, and our therapeutic difficulties thereby increased; they promised a distinct gain in a more intelligent treatment of cardiac and renal diseases in particular. He asked for a closer co-operation between clinicians and laboratory workers.

Pernicious Anæmia and Its Relation to Gastric Digestion, Based on Twenty-five Cases.—Dr. CHAS. G. STOCKTON of Buffalo read this paper and gave the following summary: Of 24 cases reported, the youngest was 32, the oldest 70; average 45 years; there were 20 males; 13 had outdoor occupation; the longest duration of illness was five years, the shortest six months and fatal; 12 were known to be dead, five living, the others unknown. All had dyspnœa on exercise and suffered from faintness and weakness; 16 had gaseous pulse, a heart slightly enlarged, and a systolic apical bruit; 6 had bruit de diable; 8 had other bruit; 22 had a distinct lemon-colored tint of the skin; 15 had a tongue strikingly denuded of epithelium; 10 had good appetites, 7 capricious and 7 anorexia; 18 complained of symptoms of stomach trouble; 10 had constipation, 8 diarrhoea, and 6 irregularity of the bowels; in all the liver was enlarged; one had 4 periods of improvement, three 2 periods, eight 1 period, and eight no periods of improvement. After his attention was called to the subject by Billings' paper, he found signs of spinal-cord involvement in six out of nine cases. Nine cases showed slight dilatation of the stomach; in 13 the gastric digestion was absent, in 8 it was very low and in three it was fairly good. Five showed evidences of gastric catarrh. Six showed no acidity of the gastric contents, one (the highest) showed a total acidity of 46, one 26, and the average about 10. Four showed the presence of combined chlorides. One showed free hydrochloric acid .05 per cent., one .06 per cent., and one .022 per cent., in all the others it was absent. Six showed lactic acid present; four showed other organic acids. The acids salts were very low, 18 being the highest, five having none whatever; seven showed the Biuret reaction; six showed rennet present. The digestion of starch was poor in all except two cases.

Dr. R. C. CABOT of Boston said that, out of 150 cases of pernicious anæmia, five-sixths showed the absence of hydrochloric acid and yet digestion went on perfectly well. Hydrochloric acid appeared to be a luxury, but not a necessity.

Dr. ALLEN JONES of Buffalo emphasized the fact that achylia gastria was more often encountered without pernicious anæmia than with it.

Dr. WM. OSLER of Baltimore said that we were still much at sea in our efforts in finding an exact pathology of this disease.

Dr. G. N. HELL of Denver, Col., had seen striking improvement when hydrochloric acid was given in large doses.

Dr. GEO. DOCK of Ann Arbor, Mich., had met with success in the treatment of pernicious anæmia with large doses of dilute hydrochloric acid, given after meals, fresh air and diet.

Dr. CHAS. G. STOCKTON of Buffalo thought that a distinct line should be drawn between achylia gastria with atrophy of the mucosa and cases of pernicious anæmia.

The Diagnosis and Treatment of Perforation in Typhoid Fever, with a Report of Nineteen Cases, of which Sixteen Were Operated upon with Five Recoveries.—Dr. MORRIS MANGES of New York read this paper. An analysis of the clinical and diagnostic features of the cases were given with the conclusions which these warranted. The relations of perforations and perforation peritonitis were considered. He said that in drawing practical conclusions from this analysis of the varied clinical features of perforation, it would at once be seen that there was no pathognomonic symptom. In suspected perforation the condition of the abdomen should be routinely observed, especially as regards tenderness, rigidity, distension, respiratory excursions, and liver dulness. Physicians expected too many and too pronounced symptoms for an early diagnosis of perforation. The best results ever claimed for nature's method has been 5 per cent., whereas by operation there has been a recovery of 26 per cent. The only exception to the rule of early operaton was that moribund patients should not be operated upon. The indications for treatment were distinctly corroborative of the importance of early operation. Condensed histories of the perforation period of the cases were appended.

A Case of Typhoid Fever with an Unusual Complication.—Dr. WM. EDGAR DARNELL of Atlantic City reported a case in which the uterine flow occurred in the third week of the fever with fatal result.

Dr. WM. OSLER of Baltimore said that the most essential and important thing was intelligent watchfulness on the part of the physician, and, in hospitals, explicit directions to be laid down for the guidance of the house physician, who thus could be on the alert for unfavorable changes in the typhoid cases which pointed to the possibility of intestinal perforation.

Dr. J. C. WILSON of Philadelphia said that in his hospitals in Philadelphia, as a matter of routine, rigidity of the abdominal muscles was always looked for. If pain, especially when associated with rigidity, was present, the patient was immediately removed to the operating room. His experience had lead him to believe that perforation of the bowel was preceded in a considerable number of cases by hemorrhage, but seldom did they occur coincidentally.

The Mortality and Management of Pneumonia.—Dr. EDWARD F. WELLS of Chicago said that pneumonia was a very prevalent disease and its prevalence was increasing; that this increasing prevalence was probably due to the wider diffusion of the more vigorous strains of the pneumococcus, made possible by the increasing commingling of people; that the pneumococcus was to be found in the upper respiratory passages of a very large proportion of healthy persons, and it was the migration of these ever present germs into the pulmonary alveoli which caused pneumonia; that pneumonia was a very fatal disease and its mortality was increasing; that the increase in mortality was probably due to the greater average virulency of the pneumococcus. He advocated the following prophylactic measures: (1) Pneumococcic sputum should be destroyed before it became dry; (2) the nostrils, mouth, and throat should be kept as clean as possible; (3) the room occupied by a pneumonic patient should be afterward disinfected; (4) respiratory catarrh should be avoided and, if contracted, should be relieved; (5) physical and mental exhaustion, privation, undue exposure to cold and inclement weather should be avoided. Among other measures employed in the treatment of pneumonia. he gave during the first few hours only three to five drops of veratrum viride every two or three hours until nausea had been produced, or the initiatory surprise of the attack had passed To combat high fever he used the ice cap and fifteen to twenty drops of guaiacol externally. He treated pulmonary œdema by energetic stimulation of the nervous system, by strychnine, of the capillaries by adrenalin, and of the heart by small doses of morphine. He approved of oxygen inhalations

A Study of a Series of Cases of Pneumonia, with Special Reference to Diagnosis and Complications.—Dr. JOSEPH SAILER of Philadelphia read this paper, basing his study on 65 cases seen in the Philadelphia Hospital in the past winter. Nearly 40 per cent. were over sixty years of age and the mortality was correspondingly high. Thirty-five cases died and 30 survived. The distribution, as determined by physical signs and confirmed by autopsy when possible, was: left lower lobe alone, 16; left upper alone, 2; right lower lobe, 12; right lower lobe, 13. The entire left lung was involved in four cases and the entire right lung in three cases. It had been asserted that leucocytosis rendered the prognosis more favorable, but from the leucocytic count in his cases no definite conclusions could be drawn. From the quantity of chlorides in the urine it was not an indication of the subsequent course of the disease, but the comparison of the excretion of chlorides in pneumonia and in other febrile diseases had shown that in the latter states the reduction was comparatively insignificant and in pneumonia always considerable, so that we could place the highest value upon it in the diagnosis of pneumonia. Of late years the importance of Skoda's sign had almost been forgotten. Two forms of bronchial breathing could be distinguished the difference being one of degree. Wooden tympany was only observed in two cases, herpes in four, icterus in three. Feeble heart action and albuminuria were comparatively common. Profound synosis was present in two cases, and in one was temporarily relieved by venesection. If severe abdominal pain was present, it was associated with tenderness in the hyperchondrium on the same side as pneumonia. The complications were numerous. There were three deaths and seven recoveries among the cases treated with antipneumococcic serum. On the whole results of the serum treatment were regarded as distinctly favorable.

Dr. DELANCY ROCHESTER of Buffalo approved early bleeding in sthenic cases, but he disapproved the administration of opium in the beginning of the disease. The poison of the disease should be gotten rid of by the proper use of laxatives, particularly calomel. Sweating was of great benefit, and he approved of venesection in certain cases.

Dr. BABCOCK of Chicago referred to the work of an Italian experimenter who attempted to demonstrate that pulmonary œdema was not due to heart failure, but to the action of the pneumococcic infection upon the pulmonary alveoli. Viratrum viride was contraindicated as were all cardiac depressants, when the blood pressure was low. Digitalis was of the greatest possible utility in the form of fresh infusions injected hypodermatically.

Dr. S. SOLIS COHEN of Philadelphia said that venesection might be employed in the commencement of the attack when it reduced the toxæmia and toward the end of the attack when the right heart was overloaded. Th keynote of success in the treatment of this disea se we individualization.

SECTION ON OBSTETRICS AND DISEASES OF WOMEN.

First Day—Tuesday, June 7.

Chairman's Address: "Last Year's Progress in Gynecology —Senile Endometritis."—Dr. L. H. DUNNING of Indianapolis briefly stated the tendencies which this branch had assumed during the past year, and said that he believed that every man should devote himself to the working out of some particular problem, and in accordance with this idea he had devoted himself to the question as announced in the title of his paper. He claimed that senile endometritis was not as uncommon as ordinarily supposed, and found that about 3 per cent. of the cases in his general practice were thus afflicted. The condition was either acute or chronic; the former he observed in a woman of fifty-four, in whom the infection was of a mixed type, one of the elements having been gonorrhœa. He also described the pathology of two chronic cases, which might have been difficult to differentiate from carcinoma or adenoma. He believed that some of the severe cases required complete extirpation of both uterus and appendages to produce a cure. His usual treatment of the ordinary cases is by gentle dilatation with a tent, followed if necessary by curettage. It was always necessary to first cure the vaginitis.

Invasion of Carcinoma of the Cervix into the Surrounding Tissues.—Dr. J. A. SAMPSON of Baltimore referred to the high percentage of recurrences following the operative treatment of carcinoma of the uterine cervix and claimed that it showed that the growth had already invaded the surrounding tissues at the time of operation and that hysterectomy alone could therefore cure the disease in but a very small percentage of the cases. A study of the anatomic relations between the cervix and the neighboring parts showed that this relation is varied by the position of the uterus in the pelvis and that the growth does not have to extend far anteriorly in order to involve the bladder, or laterally to reach or extend beyond the ureters. A study of the specimens obtained from the more radical operations demonstrated how the above took place and emphasized the importance of a wide excision of the primary growth. The reader believed that the only hope in bettering the results from the operation lay in an early diagnosis and then doing the most radical operation possible in such early cases, in which there is the best chance for a cure. A microscopical examination was always necessary to determine to what extent the lymphatics were intact. He found that where the lower ends of the ureters were involved, it was advisable to resect them and implant them through the medium of the ureteral sheath directly into the bladder. The danger of an ascending renal infection could, to some extent, also be avoided by producing a vesicovaginal fistula, artificially.

Electrothermic Clamps in the Treatment of Cancer of the Uterus.—Dr. C. P. NOBLE of Philadelphia presented a critical analysis of the results secured by the use of this instrument, together with detailed statements of the various accidents which are liable to take place in employing the method. Up to the present time he had

treated nine cases, all unfavorable and unsuited to other operative procedures, with but one death as the direct result of the operation and that from secondary hemorrhage. The main objection to the use of the method was the danger of creating fistulous communications between the vagina and the ureters or bladder. This took place in five of his cases, two of which healed, one probably will and the other two remained open. The most unfavorable cases were the ones which thus far had shown no recurrences. Concluded that early diagnosis was most important, but that in those cases which were advanced, the electrothermic clamps offered a good chance for successfully treating the disease.

Primary Chorioe-epithelioma Malignum Outside the Placental Site.—Dr. PALMER FINDLEY of Chicago after a review of published cases, reported two cases, in one of which the growth was primary in the uterine wall, in the other, in the cervix. Both presented metastatic deposits in the vagina. He found, however, that further observation on the second case proved that it was carcinoma. The case which he reported was the 21st thus far reported. The woman had had amenorrhoea for three years, followed by a return of the menses, and then intermenstrual flow, accompanied by pain and vaginal discharge. Operation was followed by cure and no recurrences were noted four months after operation. He advocated a radical operation but the prognosis should always be guarded, as there was much uncertainty regarding the appearance of metastases in distant parts.

careful pathological examination should also be made to determine the true nature of the growth, for in his second case, the collections of giant cells in the carcinamatous tumor closely resembled syncytial masses.

Dr. WATHEN of Louisville said that although he recognized the value of hysterectomy, he was entirely opposed to the removal of the chain of glands and lymphatics, on account of the time it took, the consequent danger to the patient and the fact that it was impossible to reach or to distinguish every infected lymphatic structure. He considered that the high attendant mortality rendered such a procedure unjustifiable.

Dr. CLARK of Philadelphia referred to the commendable spirit which animated Dr. Sampson's work. He considered that the removal of the glands was of prognostic value only, as their examination would reveal to what extent the disease had advanced. He believed that the cautery was usually superior to the knife, as it was possible to cook certain cells beyond the line of actual application of the cautery which would escape the dividing line of the knife.

Dr. MASSEY of Philadelphia called attention to the danger of auto-infection from metastatic deposits when employing the knife, by opening up new lymph channels. This was avoided by cauterization and he claimed that a patient could endure a current of 300 milliamperes on the cervix without anæsthesia. He considered that regular applications of the local cautery were an advantage to doing the entire procedure at one sitting.

Dr. SMITH of Montreal stated that he did not always find it advisable to wait for a pathological report but to operate on the basis of clinical symptoms of a suspicious character. He spoke of a case in which the examination of scrapings had proved negative and yet after hysterectomy the suspected disease was plainly demonstrated.

Dr. LAWRENCE of Columbus also referred to the uncertainty of the information to be derived from curettings. In selected cases he considered high amputation and thorough cauterization better than hysterectomy.

Dr. SANDBERG of Chicago stated that he believed that many cases diagnosed as cancer were in reality chorioepithelioma, but that the latter were of a lesser degree of malignancy.

Dr. CORDIER of Kansas City thought that the Pacquelin cautery afforded the casual operator a very good chance of getting good results. Cauterization also does away with the chances of infection and that had considerable to do with the liability of recurrence. After converting the elevated mass into a conical ulcer, he found the application of calcium carbide of value as a cleansing and detergent agent.

Dr. CARSTENS of Detroit insisted that our knowledge of the anatomy of the lymphatics of this region was too imperfect to warrant our being certain of the more or less complete removal of these glands. He referred to Schauta's work, who showed that the lymphatic system of the uterus was more extensive than formerly supposed. In many autopsies it was found that the recurrences took place in the cellular tissue around the lymph channels, and this could not be removed. He thought that where the diagnosis had not been made sufficiently early to permit of a vaginal hysterectomy, the case had better be left alone.

Dr. GOLDSPOHN of Chicago believed that the recurrences were so often found in the upper part of the vagina, that should be resected in great part in preference to the extensive dissection of the glands. He also recommended removing the uterus through the vagina after it had been freed from above and the abdominal wall closed.

Dr. DOWNES of Philadelphia reported on two cases of his own in which the clamp had been used, with the formation of fistulæ. He considered, however, that this was not the fault of the clamp, but of the fact that the neighboring tissues were too much infiltrated.

Drs. CAREY, CHANDLER, HUMISTON, and THEINHAUS also discussed this paper.

Technique of Wounds Incident to Laparotomy.—Dr. H. O. MARCY of Boston referred to the modifications which resulted from the introduction of the antiseptic and aseptic methods in surgery. He called particular attention to the importance of closing as far as possible all peritoneal rents and tears, or abrasions, leaving no wounded surfaces within the abdominal cavity uncovered by healthy peritoneum. The fascial layers must be most carefully approximated and the skin be united with subcuticular catgut stitch. The wound is then covered with a solution of iodoform in collodion. The skin suture should be in the deeper layers and sufficiently thin to avoid the contamination of the sweat glands. Drainage should be reserved for septic cases. Strapping or bandaging he thought was only necessary where it was expected much nausea or vomiting would take place.

Drs. GOLDSPOHN, ORTON, LONGYEAR, DORSETT, and the CHAIRMAN participated in the discussion.

Clinical Experience with the Appendiculo-Ovarian Ligament.—Dr. D. H. CRAIG of Boston after describing the anatomy of this structure, called attention to the mechanical effect on the pelvic organs of the female which resulted when the ligament was in a state of pathologic thickening and contraction. He believed that contraction probably rarely, if ever, produced pure retroversion. Six cases were reported, in one of which the diagnosis had been made before operation. In about one-third of the cases examined the structure can be demonstrated, in the remainder it is present in a varying degree. The most marked symptom which he observed was a line of continuous tenderness from the ovarian region up to McBurney's point, with pain radiating up into the hypochondrium.

SECTION ON DISEASES OF CHILDREN.

First Day—Tuesday, June 7.

CHAIRMAN, Dr. CHARLES G. KERLEY of New York.

Chairman's Address: "The Demands of the Child by Virtue of Right."—By Dr. CHARLES GILMORE KERLEY of New York City The speaker stated that so far as its physical characteristics were concerned, the child was a young animal In order that a vigorous adult might be produced, suitable nutrition, plenty of fresh air and cleanliness were absolutely necessary. In his daily life,

ere must be an absence of worry and anxiety; an sence, to a great degree, of responsibility; an absence of ork of an exhausting nature until the adult period was ached. The child should make its first year's growth id development during the first year; its second year's owth and development during the second, and so on. order to make the best adult, both physically and entally, every year of the growing period must supply its ota of physical and mental development. The child ould never do its first or second year's growing satisctorily during the fifth or sixth year, nor its fifth or xth year's growing during its tenth or twelfth year. rotracted, faulty nutrition, overwork at school, emloyment of an arduous nature in mines, stores or factories uring the developmental period left their indelible stamp n the adult, as evidenced by stunted growth, lack of idurance, lack of resistance to disease and lack of apacity for work, together with an absence of a high order f mental capacity. Those of the rising generation who ould do the nation's work, fight the nation's battles, do he nation's thinking, were those who were now receiving hat we all admitted the child had a right to demand. hey were getting food suited to the development of their odies: they received the benefit of fresh air and cleanliess, and their life was devoid of care. They were getting he benefit of secular and religious instruction. Those who were treated otherwise would form a large proportion f the future dependants, criminals and degenerates.

Erythema Nodosum in Children.—Dr. ISAAC A. ABT of Chicago read this paper. He stated that erythema nodosum was a disease of childhood which was of interest to the dermatologist as well as to the practitioner who treated children. Modern dermatologists differed among themselves as to the relation of erythema multiforme and erythema nodosum. The disease undoubtedly belonged to or was to be classified as one of the exanthematous fevers. In spite of the typical course of the prodromata and complications—among them conjunctivitis, pharyngitis, joint lesions, and, more rarely, endo -or pericarditis —Lewin was inclined to believe that the disease occurred on an angioneurotic basis. The eruption might occur after one of the infectious diseases, like rheumatism or malaria, or might arise in the midst of perfect health. The patients were for the most part children, ranging in age from two to fourteen years. The disease usually began with vague pains, gastrointestinal disturbance and fever. The temperature was usually continuous, and the disease rarely ran its course without some fever. The eruption generally occurred in the form of node-like swellings, most frequently located on the shin bones, though in some cases on the forearms and thighs, rarely on the tongue and face. The lesions were round or oval in shape, and varied in size from that of a walnut to a hen's egg. They were at first painful and tender to the touch, and tense and firm in consistence. They did not produce itching nor tend to suppurate. They were of a bright red color, and the overlying skin was tense and glossy, as though it had been polished. These nodules remained for a day or two, when the brilliant redness disappeared and was replaced by a dusky red or bluish color. In their involution, the lesions resembled those observed in a bruise, and it might take a week or ten days for a single nodule to go through its cycle.

Dr. DAVID LIEBERTHAL of Chicago said that these cases of erythema nodosum were observed more frequently by the pediatrist than by the dermatologist. The differentiation between the two affections, erythema nodosum and erythema multiforme, was very important, and it was surprising that there were some who still regarded them as identical.

Whooping-cough: a Study of Eighteen Cases Treated with the Elastic Abdominal Belt.—Dr. THERON W. KILMER of New York City read this paper. The method consisted in the application of a slightly constricted silk elastic abdominal belt to all children having pertussis. The method of applying the belt was as follows: A stockinette band was placed upon a baby with whooping-cough in the same manner as was done by orthopedists before applying the plaster-of-Paris jacket. This band extended from the axillæ to the pubes, and fitted snugly. Two muslin shoulder-straps were used to prevent the band from slipping down. Upon this stockinette a single width of silk elastic bandage was sewn, extending entirely around the body, and covering the abdomen. In a child under a year old it would be found necessary to use but one width (5 inches) of this elastic bandage; in an older child, two widths would often be found necessary to entirely cover the abdomen. This silk elastic bandage was pinned in place while very slightly on the stretch. After it had been pinned in place, it should be sewn to the stockinette band underlying it, all around its entire edge. The lower projecting portion of the stockinette band should be pinned down to the outside of the diaper or other clothing thus keeping the elastic belt smooth over the abdomen. Dr. Kilmer said he had used this belt with great success to control the obstinate vomiting of pertussis. Should the vomiting continue after the belt had been applied, the latter should be tightened slightly. In some of the most aggravated cases the vomiting had been seen to stop at once with the application of the belt.

The Chairman, Dr. KERLEY, thought the method was especially valuable in the treatment of whooping-cough in very young children, because on account of the tender age of those patients the usual strong remedies in this disease were apt to injure the stomach.

Dr. LOUIS FISCHER of New York City said that in three cases in which he had employed a modification of the method, which consisted in putting a stout binder around the chest, marked benefit resulted. In one case it was beneficial after bromoform, belladonna and morphine, in good-sized doses, had failed to control the paroxysms.

Dr. GILBERT of Louisville, Ky., said that the method, which was entirely new to him, was apparently based on a mechanical theory. He asked if there was any danger of a hernia as a result of the tight pressure?

Dr. KILMER, in closing, said he thought the *rationale* of the method was entirely mechanical, so far as he could explain it. He had never seen a hernia result from the application of the belt.

Prophylaxis of Tuberculosis in Children.—Dr. LOUIS FISCHER of New York read this paper, which was based upon a study of 5,000 cases from the children's service of a large outdoor dispensary in New York City. These children had been brought to the dispensary for the treatment of various infantile disorders, and were examined for the presence or absence or pulmonary lesions, with special reference to tuberculosis. Of these 5,000 cases, 1,700 suffered from adenoids, pharyngeal disease and catarrh of the nasopharyngeal tract. Fifty-nine showed distinct evidence of pulmonary tuberculosis, and in 9 cases tubercle bacilli were found in the sputum. Of the 59 cases that showed evidences of pulmonary tuberculosis, 43 had bone or joint tuberculous disease and 5 had Pott's disease in addition to the pulmonary manifestations. Of the 59 tuberculous cases, 2 were breast fed. Their mothers were very anæmic and dyspeptic, and showed evidences of malnutrition. Thirty-seven were bottle fed, the food consisting of grocer's milk. Eighteen were fed exclusively on condensed milk, and 2 were fed on modified cow's milk. The writer emphasized the necessity of removing mechanical impediments, such as adenoids and enlarged tonsils in the upper respiratory tract of children, and stated that such deformities as pigeon breast were the result of imperfect oxygenation of the lungs. Breast milk and fresh air he regarded as the most important factors in the prevention of infantile tuberculosis.

Dr. D. JACOBI of New York said that if the mother was tubercular, she should not be allowed to nurse her baby. In such a case, while he did not exclude the possibility of

even the probability of the milk being directly injurious to the child, the chief danger of infection was by transmission through the sputum and general environment. Numerous examples of this had been reported. Children of tubercular parents had been placed in institutions, where they had remained well, while healthy children who were brought up in tubercular families had contracted the disease simply from their surroundings.

Dr. B. ULRICH of Pennsylvaina said that he was a great believer in the hereditary transmission of disease, and yet he agreed with Dr. Jacobi that tuberculosis, *per se*, was not transmitted from parcnt to child, but the tendency, the weakness or the diathesis was transmitted, and under comparatively slight provocation, the disease developed. The best prophylactic treatment was to control the marriages of the world. At least as much care should be shown in breeding children as was shown in breeding horses.

Dr. CHARLES C. BROWNING of Highland, Cal., said that the idea of separating an infant from its tuberculous mother was impracticable, at least among the poorer classes. Those people were not able to put their children out, nor were they willing to do so, nor could they be compelled to do so, and he was not sure that it would be right if they were compelled to do so.

Dr. C. F. WAHRER of Fort Madison, Iowa, stated the case in this way: Given, the birth of a healthy child by two healthy parents. Given, the birth of a diseased child by one or two diseased parents. Let us then trade children Let the unhealthy parents take tare of the healthy child and let the healthy parents take care of the child born of unhealthy parents. Query; which of these two children would have the best chance of life? The speaker expressed the opinion that the child that was reared by the healthy parents, in spite of its inheritance, would have a far better chance than the child born of healthy parents, but brought up by the unhealthy parents.

Dr. PAULUS A. IRVING of Richmond, Va., cited the following instance as an example of the possible transmission of bovine tuberculosis to the human family: In an infant asylum in the South, the children were fed upon the milk of a single cow that had been presented to the institution. Within a year twenty-nine out of the thirty inmates gradually drooped and died. The milk was finally suspected as the cause of the high mortality, and upon slaughtering the animal, it was found to be suffering from tuberculosis.

GENERAL MEETINGS.

Second Day—Wednesday, June 8.

Oration on Surgery.—Dr. W. J. MAYO, Rochester, Minn. (See page 945.)

Symposium.—"Mutual Relations and Duties of the Government Medical Service and the Profession."

What Can the Medical Departments of the Army, of the Navy and of the Public Health and Marine Hospital Service do for Medical Science?—Dr. VICTOR C VAUGHAN of Ann Arbor, Mich. spoke for the profession. He said that the history of what the Medical Corps of the Army had given the profession in the past would serve as an indication of what might be expected from them in the future. He gave a résume of the contributions to medical knowledge that had been the result of the work of surgeons n the United States Army. He likewise reviewed the history of medicine and surgery in the Navy and Marine Hospital service. He referred to the valuable aid that the extensive library of the Surgeon-General gave to the members of the profession. He said that no greater services could have been rendered to the profession than that of the Reed commission, the application of the discovery to, by Gorgas and Ross and Carval by which Havana was tranformed from one of the dirtiest cities to a condition better than that of Philadelphia or New York, and the administrative work that had been carried on under Dr. Woods He said that we might expect good work from the consumption hospitals established by the government. Scientific research should be encouraged among men in the army by giving them facilities for carrying on original work and by breveting them for meritorious achievements in scientific work. Men should be detailed to study in the best laboratories in this country and in Europe. Special commissions for the Army or mixed commissions for both the Army and the outside profession should be appointed to study tropical diseases. The Public Health and Marine Hospital should be equipped with the best apparatus and the best men. A research laboratory should be established in the south which could be thrown open to competent men in civil life. The Naval Service should have a complete clinical laboratory. The medical profession acknowledged and was grateful for the work of the past and expected these government services to be the birth of knowledge in the future.

What Can the Medical Profession Do for the Army?—Major Surgeon WILLIAM C. BORDIN said that the fact that this subject had been brought up showed that the profession was disposed to shoulder its duties and responsibilities to the nation. To be successful in war we must be prepared beforehand, and this was as true of the medical corps as of any other department of the army. A medical corps that was insufficient to do the work of the army in peace could not be expected to do it in times of war. Victory or defeat might depend on the health of the army so the necessity for an increase in the number of surgeons in the army could not be questioned. The medical profession should be the teacher and leader of the people and should show them why this increase in the corps of surgeons was important, not only that we might have efficient services in times of war but that many difficult sanitary problems were to be solved in times of peace. A properly trained reserve corps should be established to take the place of the contract surgeons, as aside from fitness a surgeon could not perform his duties effectively unless he had rank. This question was before Congress and the American Medical Association could lend its influence in furthering this reform.

What Can the Medical Profession Do for the Navy?—Surgeon C. F. STOKES of the United States Navy said that an increase in the navy had been provided for, and the medical profession could best serve the navy by acquainting its promising young men with the inducements that the navy held out to them and by sending some of these young men to the examining board. The work on the Naval Hospital was superb and the impression that a surgeon hibernated while on board ship was very erroneous, in illustration of which he gave an idea of the scope of his work, showing that it was as broad as that of the busiest practitioner. The surgeons of the navy contributed but little to literature because of their onerous duties and their isolation, being, as they were, out of touch with all medical bodies.

What Can the Medical Profession Do for the Public Health and the Marine Hospital Service?—Surgeon General WALTER WYMAN, U. S. P. H. and M. H. S., said that the Marine Hospital Service had been founded in 1798 and had grown until it now had 300 medical officers, 22 government hospitals and 125 relief stations and 37 quarantine stations in the United States. It made visual examinations of pilots and physical examinations of life savers and immigrants. It established detention camps in times of epidemics, delved into the causes of disease in its laboratories, settled local disputes in diagnosis and passed opinion on the purity of vaccine and serums. It prevented the side entrance of immigrants and had stations all over the world where emigrants were inspected and quarantine administered. They considered themselves a product of the medical profession of the United States and the medical profession could assist them by considering them a part of itself. The service

should be in contact with the rest of the profession. The profession could assist them by maintaining a high standard of professional excellence and by raising the standard of medical education in the colleges. Coöperation with State Boards of Health officers associated with the Marine Hospital corps would be of advantage to general sanitation. They could assist the Marine Hospital service in its aspirations for a slumless country by aiding in education in sanitation and hygiene. They could give support in legislation and sympathy in aspiration.

SECTION ON MEDICINE.

Second Day—June 8.

Pathology of Arteriosclerosis.—Dr. WM. WELCH of Baltimore made a historical review of the subject. He said that in the cicatricial form of arteriosclerosis there seemed to be a peculiar localization chiefly affecting the thoracic arch in its ascending portion, and had but little tendency to extend. It was characterized by changes in the adventitia and media, and also by scar-like depressions seen especially in the intima, and associated with this were elevated plaques. At present three anatomical distinct affections, which might occur separately but more often combined, were as follows: (1) That form with inflammatory thickening of the intima resembling scar tissue; (2) That form called by some atrue arteriosclerosis, and which applied naturally to a thickening of the inner coat and a splitting of the internal elastic membrane, or the elastic muscular coat, and associated with necrotic, fatty, and hyaline degenerations; (3) That form due to syphilis or, as called by Keller and his students, syphilitic aortitis. He believed the most important underlying cause was the functional strain upon the arteries, and it was a matter of the greatest importance to learn what were the conditions associated with arteriosclerosis which were responsible for the rise of arterial pressure and cardiac hypertrophy.

Arteriosclerosis from Acute Infectious Diseases.—Dr. WM. S. THAYER of Baltimore referred to sixty-two autopsies in cases of typhoid fever in nineteen of which definite sclerotic changes were made out and in thirteen early and fresh sclerotic changes were noted, and this led him to believe that typhoid fever played some causal part in the thickening of the radial arteries. The histories of a large number of cases in Dr. Osler's wards, gone over consecutively, numbering 3,894, were examined regarding the general presence of palpable radials in cases with histories of certain diseases. The results obtained and which were shown by charts showed where no causal factor existed a general percentage of 18.9 was shown, in cases of diphtheria a slightly lower percentage, pneumonia with 19.6, malaria, 22.6, syphilis 23, scarlet fever 24, rheumatism 41, alcoholism 53.3, and heavy work 62.2. The part played by physical labor in the production of arteriosclerosis appeared to be far greater than that played by alcohol.

Arteriosclerosis of Syphilitic Origin.—Dr. C. TRAVIS DRENNEN of Hot Springs said that the connection between arteriosclerosis and syphilis, if any, was obscure. The routine treatment adopted by the profession at large in the treatment of syphilis be believed was responsible for the production of arteriorsclerosis, and the tendency of the disease itself was to produce sclerosis in various organs. He pleaded for a more rational treatment of syphilis that would lessen the danger from mercury and iodides, and possibly might eliminate the agents used in the treatment of syphilis as causative factors in the production of arteriosclerosis.

Arteriosclerosis of Nephritic Origin.—Dr. GEORGE DOCK of Ann Arbor, Mich., said that it was doubtless true that in many cases the arterial disease caused the renal disease and that it was of great clinical importance that the kidney lesion be very severe, yet latent. We often saw how under the influence of an acute intoxication, as in acute infectious diseases, severe symptoms might suddenly develop and quickly cause death, when advanced renal degeneration was discovered. It was generally accepted that a chronic nephritis in a person with previously healthy blood-vessels might cause arteriosclerosis by retention of injurious substances. The importance of hypertension in causing vascular disease was now well recognized. If there was hypertension in acute nephritis, we must admit that it might lead to disease of the intima, followed by compensatory, and later by degenerative, changes. Many cases of acute nephritis apparently severe, recovered, and he thought we must believe that when this occurred vascular sclerosis might follow. He wished to assert the possiblity of renal diseases of all kinds assisting in the production of arterial disease, and to plead for more extensive clinical investigation in order to show the extent and if possible the explanation.

Arteriosclerosis Due to Lead.—Dr. FRANK BILLINGS of Chicago said that lead readily gained an entrance into the body, and probably directly affected the blood and other tissues. It might act directly upon the cells of the vessel wall and produce a proliferative endarteritis. This was associated with degenerative processes and thickening of the media, and especially a degeneration with proliferation and thickening of the muscular coat. There was caused a chronic degeneration of the kidney substance, with well-known fibroid changes and hypertrophy of the muscular coat of the arteries. In a large number of cases brought to autopsy with nephritis a great proportion of them was associated with lead. Lead predisposed to gout, and it was a well known fact that arteriosclerosis was common in gout.

The Significance of Alcohol in Relation to Arteriosclerosis.—Dr. RICHARD CABOT of Boston said that in reviewing the literature on this subject he had found that the textbooks all asserted the importance of the excessive use of alcoholic liquors as a causative agent in the production of arteriosclerosis. In his investigation of 283 cases at the Massachusetts General Hospital, only eighteen or 6 per cent. showed arterial sclerosis so far as could be ascertained by an examination of the heart and peripheral vessels. This investigation excluded syphilitics and those over fifty years of age; if those over forty years of age were excluded the percentage would fall to less than 1½ per cent. Investigations carried on at the Massachusetts Hospital for Inebriates and at the Long Island Hospital showed very definitely that alcoholism exerted very little influence as one of the causative factors of this condition. All the post-mortem evidence that could be obtained gave that same result. He said that we must conclude that alcoholism was of slight importance as a causative factor in arteriosclerosis.

Arteriosclerosis and Angina Pectoris.—Dr. WM. OSLER of Baltimore said that there was no question about the association of angina pectoris and arterioslerosis in a very considerable number of cases. He said that arteriosclerosis presented many phases of interest; when the blood-vessels of the head were affected severe pain was produced associated with migraine. In arteriosclerosis of the abdominal blood-vessels, severe pain was rarely met with, and yet there were cases of angina pectoris in which the pain was almost entirely abdominal. The numbness and tingling of the lower extremities met with in old people, in diabetes, and in Bright's disease, was due to senile arteriosclerosis. Dr. Osler divided the cases into four groups: (1) Those in which the angina attacks were definite, distinct, and severe in young persons, in neurotic conditions recurring over long periods of years, terminating fatally, and in which the arteries showed no sclerosis whatever. (2) Cases in which the angina pectoris was associated with syphilitic arteriosclerois; these were

amenable to treatment, occurred in young men with signs of cardiac lesions, but with evidences of syphilis definite and distinct. (3) A large group of cases occurring in the presenile. (4) A group of cases occurring between the ages of fifty, sixty, and eighty.

Treatment of Arteriosclerosis.—Dr. JAMES M. ANDERS of Philadelphia divided the cases into: (1) Those due to toxic agencies in the blood, (2) those caused by the constant ingestion of either carbohydrates or nitrogenous food, and (3) those dependent upon constant hypertension, due to muscular over-exercise. The maintenance of a complete nutritive equilibrium was a potent means of preventing pathological processes which lead to arterial changes. A suitable and considerable restriction of the amount of food was the prime requisite. Massage was a useful means of prophylaxis and exercised a beneficial influence upon glandular secretions on the nervous as well as upon the vascular systems. Warm baths were serviceable in lowering the tension of both the arteries and veins. The remedies employed to restore the normal rapidity of the blood and lower the blood pressure, by dilating the arterioles, were nitroglycerin, the nitrites and potassum iodide. He believed the nitrites were strongly indicated and most effective in that category of cases in which there was an early and marked increase in arterial pressure and the heart was hypertrophied.

Dr. ALFRED STENGEL of Philadelphia emphasized the importance of the early treatment of the disease.

Dr. FREDERICK SHATTUCK of Boston referred to the multiplicity of causes of arteriosclerosis and referred particularly to the high arterial tension in men who were under very great strain.

Dr. WM. KRAUS of Memphis, Tenn., said that the etological features of the disease seemed to be associated with the circulation of toxins.

Dr. CHAS. G. STOCKTON of Buffalo thought better results were obtained from short, hot, or vapor baths. He did not believe that such favorable results could be had in the treatment of arteriosclerosis without the use of the iodides.

Dr. BABCOCK of Chicago did not think that we should attribute any special etiological influence to any one factor in the production of arteriosclerosis. The form of the alcohol should be considered as well as the excessive amounts of fluid consumed and nutritive materials.

Dr. F. R. WEBER of Milwaukee referred to certain salts which had effect upon the blood pressure, and he said he was experimenting at present with barium chloride which, like adrenalin, markedly increased the blood pressure.

Dr. BOARDMAN REED of Philadelphia said that toxins that are formed in the alimentary tract might produce arteriosclerosis, and these toxins might be formed as a sult of alcohol upon the gastrointestinal tract.

Dr. A. M. PHEDREN of Toronto, Canada, referred to an epidemic of peripheral neuritis at Birmingham and called attention to the fact that it was not due to alcohol but to arsenic. which contaminated the alcohol. He thought that other factors might be present in causation of arteriosclerosis than alcohol.

Dr. A. JACOBI of New York said that we should expect to be successful in the treatment of arteriosclerosis dependent upon syphilis by the use of mercury and the iodides. He referred to cases of congenital smallness of large and small arteries, and also to a peculiar form of congenital sclerosis that gave rise to obstruction in the peripheral circulation and which was attended by cardiac hypertrophy.

A Study of One Hundred and Eighty-Six Cases of Mitral and Tricuspid Stenosis.—Dr. JUDSON DALAND and Dr. E. L. MCDANIEL of Philadelphia made a report on a heart showing mitral and tricuspid stenosis, and gave an analytical and statistical study of 186 cases of this affection that had appeared in literature from 1809 to 1904.

Pleural Effusions in Heart Disease.—Dr. J. DUTTON STEELE of Philadelphia presented this paper and said that pleural effusions were more often unilateral with a preference for the right side. It was the general opinion that hydrothorax was apt to occur before general œdema, though many observers had reported isolated cases of right-sided cardiac hydrothorax. The theory that appeared to explain most satisfactorily the preference of these pleura effusions for the right supposed that enlargement of the heart, and especially the right auricle, could press upon the root of the right lung and obstruct the vena azygos major. However, the pressure of a dilated auricle upon the root of the left lung would not obstruct any large venous trunk analogous of the vena azygos major.

Prolonged Delirium in Pericarditis and Endocarditis, with a Report of a Case.—Dr E. M. GREENE of Easton, Pa., reported a case of acute rheumatism followed by endocarditis and pleurisy with effusion, which was marked by delirium lasting for five weeks and in which the fever was not sufficient to account for it A subsequent physical examination revealed no marked lesion.

The Limitations of Digitalis in Mitral and Aortic Regurgitation.—Dr. FRANK JONES of Memphis, Tenn., read this paper and stated that in compensatory mitral regurgitation, digitalis was indicated, and was contraindicated in aortic regurgitation. He said that there was no justification for the use of digitalis in aortic regurgitation, no matter what the condition of the heart muscle might be.

Some Points in the Acoustics of Respiration.—Dr. CHAS. E. QUIMBY of New York demonstrated the following propositions: (1) The trachial note represented the interference of pitch limit, of respiratory sounds, and that limit might be defined by a letter of the musical scale, as might every other respiratory pitch. (2) In vesicular respiration, the inspiratory sound represented the superior pitch limit of respiratory sound. (3) The passage from vesicular respiration to bronchial breathing was attended, at first, by a lowering in pitch of the inspiratory note, and later by lowering of both inspiration and expiration. (4) In vesicular breathing the inspiration was of higher pitch than expiration; in rude, bronchial and tracheal breathing, the inspiration was of a higher pitch than, or the same pitch as, expiration. There was no respiration resulting from consolidation in which expiration was of higher pitch than inspiration.

SECTION ON OBSTETRICS AND DISEASES OF WOMEN.

Second day—Wednesday, June 8.

Diagnosis and Treatment of Pelvic Deformity.—Dr. GEO. BOYD of Philadelphia directed attention to the frequency of pelvic deformity in America at the present day. To avoid unnecessary complications, it was essential that a careful study of the size and position of the fetal ovoid be made, and in addition to this the relative disproportion between the latter and the pelvic canal. The induction of premature labor would be the ideal treatment for this condition were it possible to accurately estimate the length of gestation. His experiences had not been satisfactory and he felt inclined to allow most of these cases go to term. Each case must be studied by itself. He believed that the fetal head was the most trustworthy pelvimeter and that in cases of moderate deformity, the test of previous labors should be taken as the guide. In multiparae where there was a history of previously born dead children, cesarian section should be performed.

Dr. BACON, of Chicago, said that it was not so difficult to estimate the exact length of gestation, if the time when the morning sickness first appeared and also the fetal movements. The former came on from 3 to 4 weeks after conception and the latter during the 18th week, in the majority of cases. He believed it advisable to induce

labor at about the third week and considered that the high infant mortality was entirely due to insufficient preparations having been made for the case.

Dr. CAREY, of Chicago, claimed that the prognosis depended on the size of the head as well as on the dimensions of the pelvis, and moreover on the degree of ossification to which the skull had advanced.

Heart Disease as an Obstetric Complication.—Dr. C. S. BACON, of Chicago, read this paper. He said that heart disease might be due to pregnancy or to labor, *e. g.*, myocarditis, due to toxemia of eclampsia, endocarditis due to puerperal infection. As pre-existing heart disease did not interfere with pregnancy, its frequency corresponded to the frequency of the disease. Abortion was the usual effect of heart disease on pregnancy, while dyspnœa, bronchitis, edema, palpitation, indigestion, etc. were the effects of pregnancy on heart disease. Labor itself might cause sudden death. During the puerperium one of the principal dangers in addition to the weak heart was the liability to infection, especially of the air passages. In the management of these early cases the question of inducing abortion depends to a large extent on the patient's knowledge of her condition and her circumstances. It is not advisable, however, in most cases to await spontaneous abortion. Where it has been decided to carry pregnancy to term, on the slightest indication of uterine contractions, quiet in the horizontal position should be insisted on. Corsets are dangerious on account of the pelvic congestion induced. To avoid the effects of inactivity, bed exercises should be employed. Opium might be necessary for considerable periods where abortion was imminent. The immediate indications for abortion were increased pulse and heart action and cyanosis. The administration of oxygen was most important, as it was found to be soothing and anaesthetic. Ether was the best anaesthetic for operations. Treatment should be kept up during the puerperium, no nursing permitted and the patient under observation for at least three months.

Dr. HOLMES, of Chicago, said that morphine should be stopped as soon as labor begins, as in his experience he had often found babies completely under its influence. In the third stage he believed that much relief to the woman was secured by letting her bleed, and that this could be readily accomplished by removing the placenta manually. For dilatation a small bag only should be used, as the larger sizes materially increase the intrauterine pressure. He favored the methods advocated for inducing labor in the following order: (1) bougie, (2) Vorhees bag, (3) incision of cervix, manual dilatation, Bossi dilator.

Dr. HOTCHKISS claimed that in mitral disease, the earlier the induction of labor, the safer for the patient. Such cases lost less blood than normally, and venesection might prove of advantage to relieve the condition.

Dr. CAREY, of Chicago, protested against the immediate taking away of the placenta, as the control of the hemorrhage was incomplete and the possibilities of infection great.

Dr. HASTINGS, of Toronto, also advised slow resort to the early manual separation of the placenta and was rather inclined to rely on venesection. He had no bad experiences with morphine and considered it invaluable for the dyspnoea. The symptoms were often more alarming at the seventh month, than later, and he believed that we should proceed slowly in the matter of inducing labor.

Dr. BACON, in closing the discussion, said among other things, that he believed that the patient needed stimuants and tonics after labor, rather than blood letting. Oxygen was of particular value in his estimation. The danger of the child seemed to him to be due rather to imperfect placental circulation than to the morphine administered.

The Difficulties and Dangers of Accouchement Forcé.—Dr. H. G. WETHERILL of Denver claimed that the present manual methods were dangerous, slow, and tiresome, and that the instrumental methods were likewise so, and in addition required expensive special instruments, which were often unavailable when most needed. In place of these he proposed a new method of securing dilatation of the cervix by means of a tenaculum forceps and the Sym's duck bill speculum. After dilatation of the cervix by uterine dilatators, the successive sizes of specula were introduced, while the cervix was held by the tenacula. Two specula were thus held above and below, and the stretching was secured by what was described as a rocking motion. Two cases were reported of general toxæmia, with albuminuric retinitis, but no convulsions in which the method was successfully employed.

Dr. CARSTENS of Detroit considered that the method was too slow for such cases and preferred vaginal cæsarean section.

Dr. HOLMES of Chicago thought that the method was inapplicable when the cervix was high, as it could not be reached by the blades of the instruments, and the tenacula were apt to be pulled out. The hand, in his experience, was the most available means.

Dr. BACON of Chicago thought that contamination from the anus was readily possible by the inferior speculum and doubted any advantages which the method might present.

Dr. HASTINGS of Toronto believed that the Harris was the ideal method, and that instrumental interference was only indicated in cases in which there was concealed accidental hemorrhage. Digital dilatation should, moreover, never be done without gloves.

Dr. FRY of Washington announced that Dr. Harris himself had lately realized the necessities of instrumental dilatation and had advised an instrument which was described. The speaker thought that the general adverse criticism directed against Dr. Wetherill was unfair and insufficient. It might be employed in selected cases and would seem of value in multiparæ.

Is Cæsarean Section a Rational Method of Treatment in Placenta Prævia?—Dr. J. F. MORAN of Washington, brought up this important question. He found that among twenty-four operations by twenty-one operators, the maternal mortality was 20.5 per cent. and the infant mortality 24 per cent. These were all emergency cases, but statistics of cases treated by other methods give only a slightly lower maternal mortality and a decidedly greater infant mortality. He considered that statistics were altogether insufficient to allow the formulation of rules for guidance in treating this condition. There was only a limited field for the operation.

Dr. HARRISON of New York stated that in his experience he had never seen a case of placenta prævia which he would have considered suitable for operation, and believed that surgical intevention was unsuitable, and opposed the method for thus relieving the condition.

Dr. DUDLEY of New York claimed that indications were undoubtedly present which would indicate this operation in placenta prævia and believed that every obstetrician should be fully prepared to undertake this procedure.

Dr. LAWRENCE of Columbus favored cæsarean section, because it gave absolute control of the bleeding, which could not be gained by tamponing with the foot pulled down after a version, for in these cases uterine inertia is always present.

Dr. HOLMES of Chicago believed that the operation was only applicable in rare cases. Such would be rigid os, or a contracted pelvis. The statistics have been furnished by gynecologists rather than by obstetricians, and he claimed that the cases should be turned over to the latter for the exercise of their own methods.

Dr. DORSEY considered that the presence of a placenta prævia was serious enough to warrant the induction of premature labor. The time when the patient was seen, however, dictated what operation was to be done.

Primary, Intermediate and Secondary Repair of the Anterior Vaginal Wall After Labor.—Dr. B. C. HIRST of Philadelphia called attention to the importance of examining all women after delivery to detect injuries of the urogenital diaphragm in the anterior wall of the vagina, the urogenital muscle, and its fascia. This should be done by digital examination, and it was feasible to repair even submucous injuries primarily. He advocated under certain circumstances an intermediate repair for the correction of a cystocele about the fifth day.

Dr. HOLMES of Chicago claimed that a cystocele present during the first week of the puerperium was physiological and that more time should, therefore, be allowed to elapse before undertaking operation.

Etiology and Pathology of Cystocele with a New Operation for Its Relief.—Dr. J. R. GOFFE of New York read this paper in which he stated that cystocele in virgins and nulliparæ was usually due to supravaginal elongation of the cervix, and was accompanied by a general descensus of the upper support of the vagina and the anterior vaginal wall, and a falling of the bladder. In multiparæ, cystocele was a frequent accompaniment of retroposition of the uterus, sometimes decensus and prolapse of that organ. Cystocele partook of the character of a true hernia when these conditions did not exist. The reasons for the inefficiency of previous operations was commented on, and the reader thought that the suggestions which he presented would overcome the objections. In this operation the bladder is freed in all directions through a T-shaped incision in the anterior wall of the vagina, and stitched to the uterus and the broad ligament at three points. It was claimed that by this procedure, folding of the base of the bladder was avoided and no shortening of the anterior wall resulted. Eight cases were reported in which the operation had been successfully done.

Dr. PRICE of Philadelphia said he was distinctly opposed to any operation done during the puerperium on the vagina. It was bad surgery to operate in a septic canal, and unsafe.

Repair of Pelvic Floor Lacerations.—Dr. J. H. BURTENSHAW of New York, in calling attention to the advantages of immediate repair of lacerations of the pelvic floor, claimed that the failure to obtain good results was usually due to failure to appreciate the pathology of the condition. Moreover few modern operations of secondary perineorrhapy accomplished what was alleged for them. Vaginal sulci might frequently be demonstrated without laceration of the levator ani, and their presence was not pathognomonic. To close muscular rents, the edges of the muscles must not be raw and held in close approximation until united. He believed that nothing more was gained by Emmet's operation than by Hegar's, because the deundation in each was superficial. He thought that the introduction of sutures into the sulci in the Emmet operation had a marked tendency to draw the vaginal wall downward, and to increase the traction on an already retrodisplaced womb.

Treatment of Complete Vaginal and Uterine Prolapse.—Dr. F. H. WIGGIN of New York described this condition as a reducible hernia through the pelvic floor, due primarily to the separation of the tendons of the muscles formlng this floor and the formation of a rectocele as result. He summed up the indications for treatment as, the reduction of the hernia, the obliberation of the sac (which in his experience could best be accomplished by intra-abdominal support obtained by means of purse strings sutures passed through the body of the uterus and the broad ligaments on either side), the repair of the pelvic floor, and the removal of the redundant tissue on the anterior vaginal wall.

Mutiple Abscesses of the Omentu Following Grave Septic Peritonitis.—Dr. H. O. PANTZER of Indianapolis, read this paper and reported two cases.

MYELOPATHIC ALBUMOSURIA.*

(KAHLER'S DISEASE; MULTIPLE MYELOMA).

By S. J. MELTZER, M.D.,
NEW YORK.

THE disease I am going to discuss, has, as far as I know, never yet been the subject of a paper or a discussion in this city. Although the first case was described over fifty years ago, there are at present not many more than thirty cases on record. There are reasons for the belief that the disease occurs more frequently, but is not recognized. It surely was often confounded with nephritis and probably also with rheumatism.

The essential clinical points of the disease, to state them briefly at the outset, are: pain of the bones, especially those of the trunk, the presence of Bence Jones' albumose in the urine, and a more or less rapid decline leading invariably to a fatal termination. The occurrence of the albumose in the urine is pathognomonic for this disease. With this knowledge in mind such cases will not escape recognition by the careful physician.

The underlying basis for my communication is the report of a case of this disease which occurred in my private practice about a year ago. As far as I know it is the first case to be recorded in this city.

A. B. R. was a tall, well-built man, forty-five years of age, of a dark, sallow complexion. He had a chronic pharyngitis due to excessive smoking and frequently suffered from spasmodic laryngeal coughs. During the five years I knew him he had one mild attack of bronchitis lasting about a week. His lungs were sound as were all his other organs.

In the first week of May, 1902, he consulted me for a pain on the left side in about the sixth intercostal space, one or two finger breadths to the left of the mamillary line. As he was then troubled with laryngeal coughs this pain annoyed him greatly. The application of a local sedative relieved him completely within two days. A few weeks later he again consulted me for a pain which was now located further back, extending about between the fifth and seventh intercostal spaces. This time the pain was severer than before and there was also an elevation of temperature to nearly 102° F. Physical examination revealed the presence of a pleuritic effusion of moderate extension. I considered it of rheumatic origin and treated it with salicylate of sodium. Pain, fever, and effusion disappeared completely at the end of a week. For about five months I heard no more of him. Then at the end of October I was called to see him for a very severe pain in his thigh at about the juncture of the middle and upper thirds. He told me that for the last few months he had often had pains in various parts of his trunk, but two or three of the salicylate powders had relieved him each time. The present pain, however, exceeded in severity all previous attacks. He had already tried local applications of heat, and of various liniments, and he had taken a number of the salicylate powders with no relief whatever. The soft tissues were not even tender, the pain was apparently located within the bone. I thought of osteomyelitis; there was, however, no fever nor any other sign of an infection. I tried aspirin, and again he was completely relieved. He was a traveling salesman and soon after went on the road. The next time I saw him was on the 11th of January, 1903. He told me he had never felt entirely well again. The pain in his thigh had not returned, but now his back troubled him. The pain was dull but continuous and was not relieved by aspirin. He located his pain in the lumbar region. He looked paler than usual and said that he felt tired. Examination of the lungs, heart, etc., was perfectly negative. But examination of the urine revealed the presence of a large quantity of albumin. I have no record, but am fairly sure that the urine was examined during his attack in May, and that it did not contain any albumin. The examination of the urine was made in the office by the routine method of heat and nitric acid. On subsequent examination of the test-tubes the albumin seemed to have increased in bulk. Nevertheless the microscopical examination revealed nothing indicative of a disease of the kidneys; there were neither casts nor renal epithelia nor any other formed elements. Within a short period, however, the problem was answered, the "albumin" was essentially Bence Jones' albumose. Now the diagnosis became clear, the poor man had what is termed by the majority of writers multiple myeloma, and with it the prognosis also became frightfully clear: there were no hopes for him.

The pains which the man variously had in his ribs, in other bones of his trunk and in his thigh were not rheumatic, and the relief which the various drugs had apparently afforded him was not due to these drugs. They were the pains which were observed in nearly all the cases of myeloma, and which appeared and disappeared regardless of any treatment.

Within a week after I saw the patient he took to his bed, where he remained till his death, which occurred about five weeks later. The pains in the back became very severe, they were confined, at first at least, to the left side of the upper two lumbar vertebræ. The eleventh rib also soon became very painful. The patient could not move, and even each breath gave him pain. His chronic pharyngitis now became a source of great suffering. He could not clear his throat from the accumulated mucus, which led to a continual sense of suffocation and to a laryngeal cough with agonizing pains. Opiates made matters still worse. Salicylates had not the slightest effect. For nearly two weeks the pains did not let up and the patient had no sleep and no rest. Finally, however, I found a reliable remedy for his pains in the continual application of ice on all the tender spots. As time passed many circumscript spots on the various bony parts of the thorax became very tender, especially the fifth and sixth dorsal vertebræ; but the application of ice afforded an infallible relief in all cases. Strong pressure or rough handling of any part of the chest caused prolonged pains. An energetic percussion by a phy-

*Read at the meeting of the Harlem Medical Association.

sician over the upper part of the sternum caused such an intense pain that the place had to be kept covered with ice for about ten days. No swelling nor palpable roughness could be discovered on the ribs or other bones of the body, and no spontaneous fractures occurred. When the patient occasionally sat up he carried himself as erect as ever. But he had no strength to sit up longer than five minutes at a time.

The patient frequently had diarrhœa accompanied by colic, both independent of any medication. And even when free from diarrhœa and colic, he continually complained of a sense of a heavy weight in his stomach. He also had occasional attacks of nausea and vomiting. At no period of the disease was the temperature above 99° F. There was no œdema. The lungs remained free. There was no enlargement of the lymphatic glands, the spleen, or the liver. The heart sounds were at first perfectly clear. Then a systolic murmur developed which gradually became louder and extended over the entire cardiac region. His natural pallor increased, but by no means to any striking degree. The pulse rose gradually to 120, the respirations became rapid and shallow. The patient became sleepless and very restless, and died apparently in an attack of pulmonary œdema on the 24th of February, 1903. While I was from the start quite sure of the fatal end, the final decline set in and terminated with unexpected rapidity. It is possible that an intense excitement which prevailed among the family at that time might have hastened the unavoidable end.

I regret that no blood examinations were made, and that no *x*-ray picture was taken. Especially the latter I consider a great loss, since no autopsy was obtainable, and there is nothing to support the diagnosis of myeloma in this case except the clinical evidence.

To recapitulate briefly, we have here a case with no other symptoms except pains occurring at intervals, especially in the ribs and vertebræ, the presence of Bence Jones' albumose in the urine, a rapid course and fatal termination. The essential diagnostic point is, as stated above, the presence of the albumose in large quantities in the urine. Before giving some details about the behavior of the urine in this case, we might say a few words regarding albumoses and their reactions in general.

The end product of a gastric digestion of albumin is, as you know, peptone, But in the gradual transition from albumin to peptone a number of intermediary products make their appearance; they are all termed albumoses. There are primary albumoses: proto- and heteroalbumoses, and secondary albumoses: the various deuteroalbumoses. We are not interested here in the particulars of these chemical bodies. It will suffice to state that in general they have some characteristics in common with albumin, and others in common with peptone. Thus, for instance, like albumin they coagulate, or are precipitated by mineral acids, and like peptone they remain fluid at the boiling temperature.

The following procedures will bring out rapidly and easily the essential characteristics of the albumose in the urine. Addition of nitric acid to some of the urine in a test-tube will cause a bulky precipitate, more bulky than a precipitate of albumin. This precipitate redissolves on being heated to the boiling temperature—coagulated albumin is not redissolved again by heat; on the contrary it becomes more compact. When urine containing the Bence Jones' albumose is heated up slowly it will be noticed that at a comparatively low temperature of about 130° F. the urine becomes turbid, and coagulates when heated only a little more. However, when the temperature approaches the boiling point the coagulum dissolves again to a great extent, the urine remaining only slightly turbid. When cooled, a heavy precipitate reappears, to disappear again on reheating the urine to the boiling point. It is characteristic for albumose to coagulate at a comparatively low temperature, redissolve at the boiling point, to precipitate when cooled, and dissolve again on heating. As in our routine work we never gauge the temperature, it is practical never to be satisfied with the appearance of a coagulum but to wait until the urine starts to boil; we will thus never overlook the presence of an albumose. For the differential diagnosis between the Bence Jones' albumose and the other albumose bodies we may bear in mind the following points: It differs from the secondary albumoses (deuteroalbumoses) by being precipitated by copper sulphate or copper acetate. It differs from protoalbumose by being precipitated by sodium chloride even in a neutral solution, which it has in common with heteroalbumose, with which it was, indeed, thought to be identical by many writers. Bence Jones' albumose, however, differs from the heteroalbumose by not becoming precipitated by dialysis, or still simpler by remaining in solution even when considerably diluted with water. However, for practical purposes, it is sufficient to establish by the simple heat-tests that we have to deal with an albumose. The presence of a large quantity of albumose in the urine is, according to the present state of our experience, indicative of a malignant disease of the bone-marrow or of multiple myeloma. We shall return to this point later.

The quantities of urine which my patient voided varied between 1500 and 2500 c.c. in twenty-four hours, and depended upon the quantity of fluid he had taken. He was from the start very thirsty. The urine had an acid reaction, the specific gravity varied between 1015 and 1023. The urine seemed to resist the usual decomposition; even after weeks it did not become ammoniacal. But a urine which was kept for a year without the addition of an antiseptic was now found to contain hardly a trace of albumose. The urine to which crystals of thymol were added is still in good condition in every respect. The albumose which it still contains amounts to 12 p. mille. In a note on a specimen of the urine which was examined on the 14th of January, 1903, it is stated that the albumose amounted to about 5 p. mille. The quantity of albumose was estimated by the Esbach solution, which is reliable, since picric acid coagulates albumose as well as albumin. The few reactions we are going to demonstrate to you to-night will be made on the urine preserved by thymol. The laboratory of physiological chemistry of the College of Physicians and Surgeons is still in possession of a considerable quantity of this rare urine. A further report on certain chemical details will be rendered some time later by Dr. John Auer.

The albumose under discussion was first described by Bence Jones[1] in 1847, who found it in a urine sent to him by a Dr. Watson from a patient of his. The clinical history of the case was described later, in 1850, by Dr. MacIntire.[2] A man of forty-five years suffered at intervals for more than a year excruciating pains in the chest, back, and loins. At the post mortem it was found that the ribs were soft and brittle. The anatomical diagnosis was osteomalacia.

The next case was described in 1883 by W. Kühne.[8] The historical background of this case is not without interest. Virchow di cove ed in the bone-marrow of a case of osteomalacia a substance which he considered similar to the albuminous body found by Bence Jones in the urine of a patient suffering presumably from the same disease. Kühne, who became chemical assistant to Virchow in 1861, grew greatly interested in that subject, and was continually on the lookout for a urine in os'eomalacia. When he was called to the University of Amsterdam he unearthed there by the aid of Stokvis a case under the care of Merkus Doornik, the urine of which contained the Bence Jones' albuminous body. When Kühne later went to Heidelberg the urine was collected and sent to him by Stokvis. The albuminous body was precipitated by alcohol, and preserved for fourteen years. Kühne's studies of that substance were not made known until his classical and celebrated studies on albumoses were completed. His article on the albumose of the urine of that case followed immediately after the publication by him and Chittenden of their studies of the albumoses of gastric digestion.

The patient, whose urine Kühne investigated, was a man of forty who suffered from pains, increasing weakness, and a gradually developing deformity of the bones of the trunk. There was no autopsy, but the diagnosis was osteomalacia.

The third case on record was described by Kahler[4] in 1889. It was that of a physician (Dr. Loos), with a sad history of suffering for about e ght years—the longest period on record. The essential symptoms were again intermittent agonizing pains, increasing deformity of the spine, increasing weakness, and the presence of the albumose in the urine. The chemistry of this urine was studied by Huppert,[6] the clinical symptoms were scrutinized by Kahler, and the post mortem was made by Chiari, all three celebrated men in their lines. It was found that in this case the seat of the disease was in the marrow of the sternum, ribs, and vertebræ. There was extreme osteoporosis, caused by tissue containing large round cells. The diagnosis during life was osteomalacia. However, in 1873, a malignant disease of the bone-marrow was described by v. Rustitzky,[9] which he termed multiple myeloma, and which was apparsently similar to the condition found in this case. Similar cases were described by Zahn[7] in 1885. The disease consists in a more or less diffuse neoplasm, sarcomatous in character, appearing simultaneously in several bones of the trunk without forming any metastases. The tumor consists of round cells which do not differ greatly from the normal cells of the bone-marrow. It replaces the bony structure in the cavity of the bone, erodes also the cortex, causes sometimes external swellings of the bone, and also spontaneous fractures. Kahler now changed the diagnosis of the case to that of multiple myeloma. Analyzing further the cases of Bence Jones and Kühne, Kahler came to the conclusion that these also were multiple myeloma and not osteomalacia. Furthermore, in no case of osteomalacia was the urine found to contain albumose. Led by all these considerations, Kahler put forward the statement that the presence of Bence Jones' albumose in the urine is pathognomonic for multiple myeloma. Subsequent experience has, so far at least, justified this assumption. Most of the Italian writers and some Germans designate the pathological condition under discussion as Kahler's Disease.

Since Kahler's publication the number of reports of such cases is rapidly growing. I need not enter upon an enumeration and analysis of these cases, since this was done recently in publications in this country by Charles E. S mon[5] and by F. Parkes Weber.[6] The latter author has enumerated in his article of last June, twenty-eight reliable cases. In these were not included one of Milroy,[10] three cases of Anders and Boston,[11] one of Boston[12] alone, and one of Vickery.[13] Counting also my present case there would then be about thirty-five cases on record. There are cases on record of multiple myeloma, with "albumin" in the urine, while at the post mortem the kidneys were found to be normal. Again pathological cases were reported recently of characteristic multiple myeloma without any clinical notes whatsoever There is one fact in the history of these cases which indicates that the disease is probably more frequent than the number of publications might show. Of these cases two occurred in the clinic of Lichtheim in Königsberg, three came from Amsterdam, three from Boston, four from Philadelphia, two were reported by Hamburger,[14] two by Bradshaw, and two by Weber. It is instructive that Weber, even in his second case, d'd not discover until a ter two months that the albumin in the urine was really albumose. Jochmann and Schumm[17] have, as late as 1901, described their typical case even after the post mortem as one of the osteomalacia, and only after a remonstrance by Bradshaw have they published it again under the head of multiple myeloma.

Most of the reports came from Germany. From this country nine cases were reported. Not a single report of an unquestionable case seems to exist in the French literature. The sad case of Dr. Calrat,[15] a prominent physician in Lyon, was only briefly described by Bradshaw in the *British Medical Journal*. It is not probable that the disease exists more frequently in those places from which more frequent reports come.

As to the diagnosis of these cases, we may, for the present, state that, in general, myeloma and the presence of albumose in the urine belong together. Although there are cases of myeloma in which no albumose was found in the urine, the latter it seems was not examined continually and long enough to make sure that there was no albumose at any time of the disease. In some of the reported cases of myelopathic albumosuria the albumose set in late or disappeared again. There is one case on record in which the urine contained the Bence Jones' albumose while the bones contained no myeloma; it is the one reported by Askanazy,[20] it was a case of lymphatic leukæmia. A few cases have had complications. Ellinger's[21] patient had a febrile disease with jaundice; Fitz's[22] first case had myxœdema; Vickery's[23] case had pernicious anæmia. In most of the uncomplicated cases in which a blood examination was made the conditions were found to be not much altered. Except for a reduction in the hæmoglobin, there were nearly the normal number of reds, no poikilocytosis, only few nucleated reds, the normal proportion between white and red cells and also a normal proportion between the polymorphonuclear leucocytes and mononuclear lymphocytes.

In some cases there were swellings of the bones, spontaneous fractures and considerable deformity. It seems that these complications occurred more frequently in cases in which the disease was protracted.

Nervous symptoms like paralysis and anæsthesia of circumscribed parts have been mentioned by many observers. Some ascribe it to anæmia and others (Coriat,[24] for instance) attach to it a prime importance. However it does not seem that these

nervous phenomena are essential symptoms in this disease.

The kidneys were found affected in only a few cases. In quite a number of cases there were intraocular hemorrhages. Pains in the bones of the trunk have been present in nearly all the cases. I may therefore state again that for the present intermittent pains of the bones, the presence of albumose in the urine in considerable quantity and a steady decline in health warrant the diagnosis of multiple myeloma or myelopathic albumosuria. The last mentioned term has been given to the disease by Bradshaw,[25] and I prefer it to multiple myeloma since it comprises the anatomical as well as the clinical findings of the disease.

The course of the disease is variable. The longest was that of Dr. Loos; it lasted eight years. In some cases it lasted less than a year Death is caused by exhaustion or by an intercurrent disease.

One word with regard to treatment. We know for the present of no remedy for it. I have tried bone-marrow with some perseverance; it had apparently no favorable effect whatsoever.

It is worth recalling that in this case ice relieved the pain, and t was the only remedy which did relieve it.

THE PRESENT STATUS OF THE SURGICAL TREATMENT OF CHRONIC BRIGHT'S DISEASE.*

By A. A. BERG, M.D.,
NEW YORK.
ADJUNCT SURGEON TO MT. SINAI HOSPITAL.

Newer methods of investigations have materially aided the study of chronic diseases of the kidneys. The separate collection of the urines, with the ureteral catheters, enables us to determine with absolute certainty whether one or both kidneys are diseased; the chemical, microscopical, and bacteriological examinations of the separated urines collected by the ureteral catheters throw light upon the character of the kidney inflammation; whilst the determination of the freezing point of the combined and separated urines and of the blood gives us accurate information of the function of both organs and of each individually.

The intimate knowledge it is thus possible to obtain of the condition of the kidney and its function, enables us to apply our therapeutic procedures much more rationally than has heretofore been possible. Of late the surgical treatment of chronic nephritis has come prominently before the profession.

It is to the indications for such surgical therapy, and to the operative procedures that are employed, that this paper is devoted.

At the very outset the writer desires to clear the atmosphere of the inaccurate terms which are commonly associated with the chronic diseases of the kidneys.

It is our custom to apply the generic term of chronic Bright's disease to the chronic parenchymatous nephritis (large or small white kidney) and the chronic interstitial nephritis (contracted kidney). These chronic parenchymatous and interstitial forms of nephritis have been erroneously called medical nephritis, "Nephritis Médicales" by the French and American writers, in contradistinction to those chronic affections of the kidneys, in which the formation of pus, or the retention of urinary and inflammatory products within the pelvis or substance of the organ demand operative treatment viz., in incision and drainage. To these latter the name of surgical nephritis has been given.

Chronic Bright's disease is, however, a generic term, and by it we understand definite pathological conditions of the kidneys. It cannot be used synonomously with the term medical nephritis, because hitherto we have employed only medical treatment in the cases of chronic Bright's disease. In the last decade operative therapy has been used with success in some of the cases of chronic Bright's disease.

This proven value of surgical measures in *some cases* of this disease has led Edehohls to advise operative treatment for *all cases* that are fit surgical risks. He would make chronic Bright's disease of the kidney "a surgical nephritis."

It will be shown, in the further course of this paper, that chronic parenchymatous and chronic interstitial nephritis, follow a variety of causes; and that it is impossible either by pathological anatomy, or by the chemical examination of the urine, or by the clinical symptoms, to determine to which cause the chronic nephritis is due. It will be also shown that the chronic Bright's which is due to some of these etiological factors is improved—yes, even cured—by operation, whereas the chronic Bright's due to other of these causes is not only not improved but is even made worse by such therapy.

Because of the favorable effect of operation upon some cases of this disease, we are not entitled to

*Read before the Eastern Medical Society.

accept Edebohls' suggestion that all the cases of chronic Bright's disease should be treated by operation. Our experience does not permit of the entertainment of such a proposition. Chronic Bright's disease is neither exclusively a medical nor a surgical nephritis. As we learn more of the kidneys in health and disease, we will apply our therapeutic procedures more intelligently and more rationally. Both the medical and surgical therapy have their value, and the indications for the employment of the one or the other will be the duty of the clinician and scientist to ascertain.

Method of selection of cases which are to be treated medically or surgically.—Since Edebohls first proposed the operation of renal decapsulation for the cure of chronic Bright's disease, some of his followers have tried to determine, both from their own experience and from that of other workers, the value of this operation in the different pathological varieties of this affection.

However good a division of the cases of chronic nephritis from a pathological standpoint may be, in order to differentiate those in which the parenchyma is chiefly involved from those in which the interstitial tissue is the main site of disease, such a classification is absolutely worthless as a basis and guide for the rational employment of our therapeutic measures. For, in the first place, it is not always possible to state from the clinical symptoms and the urinary examination the exact pathological changes in the diseased kidneys, and in the second place, and much more important, is the fact that in their pathological anatomy, both macroscopically and microscopically, two kidneys may present exactly the same lesions; and yet in the one case operation would be followed by an excellent result, and in the other it would not. Thus it has been shown by Rovsing* that bacteria may occasion in the kidney to a chronic parenchymatous or interstitial nephritis that resembles in every detail the chronic nephritis due to disturbances in metabolism. Yet the former are often curable by operation whilst the latter are not.

It is thus evident that a pathological division of the cases does not afford a basis for fixing the indications for the employment of the medical or surgical treatment.

To aid us toward this end, the writer begs to suggest an arrangement of the cases according to their etiology: Thus:

(*a*) Those due to malposition, either congenital or acquired.

(*b*) Those due to the irritation of a foreign body, as a stone.

(*c*) Those due to the toxins of bacterial life, *e.g.* scarlatinal nephritis, nephritis of measles, rheumatism, etc.

(*d*) Those due to bacterial action, exclusive of the tubercle bacillus, *e.g.* coli group, staphylococcus, streptococcus, etc.

(*e*) Those due to general metabolic disturbances resulting in sclerosis of the internal organs, and blood-vessels. (Dr. Alfred Meyer has suggested the name of organo-sclerosis for this condition.)

(*f*) Those due to new growths.

(*g*) Those due to disturbances in the general circulatory system.

(*h*) Those due to chronic suppuration and chronic exhaustive diseases.

Such a classification helps us to appreciate the fact that the chronic disease may affect one kidney or both, depending upon whether one or both organs are subjected to the factors which produce the disease. It is to be especially noted that the same cause does not always occasion the same lesions in the two fellow organs; thus in one kidney there may be a chronic parenchymatous nephritis, while in the fellow organ there is a chronic interstitial nephritis, or a chronic degeneration or minute multiple abscesses. (See case of Edebohls quoted below.)

Let us consider a little more in detail these various etiological factors in the production of chronic Bright's disease.

An acquired or congenital displacement of a kidney usually causes a chronic nephritis in the malposed organ alone; the fellow organ may later on also become the seat of a chronic inflammation.

If a stone occupy the pelvis of one kidney the irritation and congestion it causes will excite in that organ alone a chronic nephritis.

The chronic nephritis, secondary to the toxins of the acute and chronic infectious diseases, is usually bilateral, though one organ may be more markedly affected than the other.

Thus a case reported by Rovsing,† page 298, Case 5: Young male, thirty-four years old, had typhoid fever eight years before he came under observation, otherwise his previous history was entirely negative. Four weeks after his convalescence from typhoid fever, he was suddenly taken with severe pain in the right lumbar region, and noticed at the same time that his urine was cloudy as though it contained sand. He consulted a physician, who diagnosed nephritis, and put him to bed. Urination at the time was somewhat painful, and the urine continued to be highly colored and contained a sediment. After a week's rest in bed, he got about but continued to suffer from pain in his right lumbar and right pelvic regions. He never had any hæmaturia macroscopically, though on one occasion red blood cells were found in the urine. He had been on internal and dietary and hydrotherapeutic treatment without deriving any beneficial result therefrom. Physical examination revealed a pale, thin, but otherwise healthy man. Kidneys not enlarged. The urine, taken separately from each kidney by sterile ureteral catheter, was acid clear, contained slight amount of albumin in both. Microscopical examination of the centrifugalized specimens showed in both, few uric acid crystals, numerous epithelia and few lencocytes and few granular casts. No bacteria, either in spreads or culture.

The constant pain in the right kidney region gave the indication for surgical exploration. The kidney was found enlarged; its lower pole appeared to be normal; the upper pole embedded in dense fibrous perinephritic adhesions. The kidney tissue corresponding to upper pole was cyanotic and somewhat friable. No calculi present. A section was excised for examination. Acupuncture and nephrolysis were carried out.

Microscopical examination of the excised section showed it to be the seat of a glomerulo-nephritis and proliferation of the interstitial tissue. The result of the operation was entire disappearance of the pain. The albuminuria disappeared after the operation, but when the patient resumed his usual work, the albuminuria returned and has persisted ever since. This will be referred to again under the consideration of treatment.

In this case, the post typhoidal toxic nephritis was a bilateral one, but the right seemed to give the more marked clinical evidences of disease.

When bacteria, exclusive of the tubercle bacillus, themselves attack the kidneys they may cause in them a variety of lesions; *e.g.* an acute degeneration, single or multiple abscesses, and chronic nephritis. As far as recent searches would go to

*"Operationen bei chronischer Nephritiden," *Mitteilungen aus der Grenzgebieten der Medizin und Chirurgie.*

†Already cited.

show, the pyocyaneus produces a contracted kidney; the coli bacteria may remain a long time without inducing any alteration of the kidneys; but certain virulent members of the coli and typhoid groups produce disseminated chronic abscesses. The staphylococcus produces a large white kidney; likewise the proteus group. The streptococcus a contracted kidney. Rovsing attributes the chronic nephritis not to the bacteria themselves, but to the decomposition of the urine they cause, and the consequent irritation of the kidney these products of decomposition give rise to.

Both organs may be similarly affected or the lesions may differ in the two kidneys. Further, the disease may be unilateral or bilateral.

As evidence of a unilateral bacterial disease of the kidney, the following history is cited:

Walter B., six weeks before he came under observation had a small wound of the foot from the pressure of a tight shoe. The wound became infected and healed slowly. During the course of its healing he commenced to have fever, pain in the left lumbar region, sweating, and gradual emaciation. Urine was clear and contained some albumin.

Suspicion of acute miliary tuberculosis was entertained. Two weeks before he came under our treatment an abscess, presumably of the prostate, was incised and much pus evacuated; no gonococci or tubercle bacilli were found in the pus.

At the time of his admission to the hospital he was emaciated, pale; temperature between 103°-105°; internal organs normal. In left hypochondrium and left lumber region was a large tender mass, fluctuating, corresponding to the left kidney; urine acid, clear, trace of albumin; microscopically many bacteria; only once hyaline casts. Rectally, the prostate felt of normal size and consistency. Just above it was the scar of the incision which had been made to evacuate a purulent collection. The induration which remained surrounded the lower end of the left ureter.

Diagnosis.—Left pyonephrosis, occluded left ureter, periureteral abscess. Cystoscopy revealed a normal bladder. *Right ureteral orifice* normal, clear urine discharged from it. Easily catheterized. *Left ureteral orifice* congested and swollen. Discharges nothing. A catheter could not be passed further than one-half inch into the left ureter, on account of some obstruction. Urine from right kidney was amber, cloudy, acid, faint trace of albumin, no sugar, 2 per cent. urea; microscopically urates. Operation was advised. Left kidney region exposed by a lumbar incision; a high perinephritic abscess was evacuated. Pus was thick, white creamy, no odor; culture, sterile.

The kidney was felt to be enlarged, and soft and friable; aspiration yielded thick pus. It was decided to drain the perinephritic abscess for a few days before the kidney was exposed, lest the manipuations attendant upon a satisfactory delivery of the organ spread the infection to the surrounding cellular and peritoneal tissues. The perinephritic tissues under frequent change of dressings and with good drainage, cast off the sloughing parts. The patient had a number of chills and very high temperatures during the next few days, and a week later the kidney was attacked. The perinephritic abscess cavity was thoroughly curetted and irrigated; and the previous incision was enlarged forward. Kidney was high *in situ;* it was much enlarged and friable; considerable adhesions at the upper pole. It was delivered on to the back. It was found to be riddled with small abscesses, between which the cut surface had a pale, waxy, jelly-like appearance. Nephrectomy was decided upon. Function of the other kidney good. The pedicle of the left kidney was secured with a mass rubber ligature and the organ ablated. Open treatment of the wound. The temperature abated at once—no further chills. The amount and character of urine secreted by right kidney were entirely normal. Uninterrupted convalescence.

Discharged, cured.

Specimen.—Kidney enlarged, pale gray in color; fibrous capsule adherent; contained two large infarcts, located one in the middle and the other in lower pole—each holding about 2 ℥ of thick pus.

Pathological report: Purulent inflammation.

As evidence of unilateral chronic kidney disease from bacterial infection, resembling in every way the kidney of chronic Bright's disease, the following history of Rovsing is quoted: A male, thirty-five years old, with negative previous history, suffered for one-half year with constant pain in the left kidney region, hæmaturia, and frequent, burning urination. He was, when he came under observation, pale, anæmic, and emaciated. The left kidney was enlarged and tender to palpation. The urine was ammoniacal, contained blood, epithetial and granular casts; white and red blood cells, and staphylococci. *Cystoscopy* showed cystitis, hemorrhage from left kidney, clear urine from right. Diagnosis of renal calculus was made. Exposure of left kidney showed it to be large and white; on section it was of jelly consistency, just as in the diffuse parenchymatous nephritis. Kidney was drained; a sudden severe hemorrhage from an anoded artery, two weeks after the operation, necessitated nephrectomy. Right kidney proved itself normal. Left kidney, diffuse parenchymatous *nephritis*, and in the tubules and interstitial tissue numerous *staphylococci*.

As evidence of the bacterial infection producing different lesions in the kidneys of the same patient, the following history is quoted from Edebohls: In the one kidney are all the evidences of chronic Bright's disease, in the other multiple *abscesses*.

Case No. 18—In abstract: Mrs. C. B.; thirty-nine years old, during puerperium developed septic symptoms, from a sloughing uterine fibroid. Abdominal hysterectomy was performed; during the convalescence, from which she passed through a severe pneumonia. Two weeks after defervescence from pneumonia an acute infection of right kidney developed, characterized by painful swelling with pyuria and increased amount of albumin and casts. Her severe sepsis forbade immediate operation, which, however, had to be undertaken several months later on account of the continuance of the sepsis. The right kidney was found riddled with innumerable abscesses and its pelvis filled with pus. Nephrectomy was done. Professor Brooks reported on the microscopical examination of the kidney. Sections showed typical histological characteristics of multiple abscesses. In the abscess area was found a thick bacillus corresponding morphologically to a species of the Proteus.

After the operation the patient's condition improved, and she gained flesh and strength, but her urine contained albumin and casts. *Gradual evidences of chronic Bright's disease developed and Edebohls performed decapsulation on the remaining kidney.* A bit of kidney tissue came along with the capsule and it was examined by Dr. Brooks, who reported as follows: Sections show decided histologic evidences of multiple foci of nephritis of infectious septic type. As far as was possible to determine, these foci were confined to the areas corresponding to terminal arteries, and consequently had a wedge-shaped outline. In the diseased areas the tubules presented granular and partially disintegrated epithelia often detached from the mem-

brana propria; and the lumena were frequently filled with polynuclear leucocytes, fragments of epithelial and blood cells and detritus. In some were hyaline casts.

It is to be regretted that in this case Edebohls gives no description of the gross macroscopical appearance of the second kidney, but this is certainly an example of a bacterial infection of both kidneys (although the incomplete examination of the urines for bacteria does not permit us to state this *absolutely*, for the second kidney) producing multiple abscesses in the one organ, which necessitated its removal, and the lesions of chronic Bright's disease in the other, which led Edebohls to decapsulate it. He was under the impression that he was dealing with an ordinary form of Bright's disease, instead of a chronic bacterial nephritis.

These three histories have been detailed in order to show that the action of bacteria upon the kidneys causes lesions that may be in the nature of multiple abscesses, or of a chronic Bright's disease (parenchymatous or interstitial nephritis). The clinical symptoms in the last two cases were exactly the same as those given by chronic Bright's disease, and the urine showed changes of a similar kind, Even Edebohls diagnosed his case as one of chronic Bright's disease, and was led to perform decapsulation in the hope of curing the patient. What the writer wishes to impress is that bacteria, and the toxins of bacterial life can cause a chronic nephritis, that pathologically and clinically resembles the cases of chronic parenchymatous and chronic interstitial nephritis, which are classed as chronic Bright's disease; and that the lesion may be unilateral or bilateral.

We now come to a group of cases of chronic nephritis, in which the disease from its very incipiency, seems to be of a bilateral character. There is no clinical evidence afforded by separation or segregation of the urines which permits us to conclude that the affection is at its very beginning unilateral, though we cannot deny the possibility of such an occurrence. Of the real cause of the disease in this group of cases we know practically nothing. For some reason or other, usually ascribed to metabolic disturbances, there sets in a gradual sclerosis of the connective tissue structures of the various organs; of the heart, blood-vessels, lungs, liver, kidneys, etc. The sclerosis may develop in all these organs simultaneously, or commence in one and gradually affect the others. Thus it is quite frequent for the sclerosis to develop first in the kidneys, which become, as a consequence, the seat of a chronic interstitial inflammation.

The *disease* seems to be a *general constitutional one*, with *local lesions* in the *connective tissue membranes* of the *various organs*. It occurs in the young or old, it may originate and develop in a number of organs at the same time or start in one organ, *e.g.* the kidneys, and gradually become manifest in the others. In the kidneys the affection seems to be always bilateral. The writer need give no concrete examples of this form of chronic nephritis. Numerous cases are familiar to you all, for here are grouped those cases of chronic Bright's disease with emphysema, arteriosclerosis, myocarditis, cirrhosis of the liver, etc.

New growths affecting one or both kidneys may induce in the affected organs a chronic nephritis. Such a chronic nephritis may for a time entirely obscure the symptoms of the neoplasm.

The chronic nephritis due to disturbances in the general circulation, *e.g.* from heart disease, is well known. It is always bilateral, and the pathological lesions of both organs are of a similar type. Likewise the chronic nephritis due to prolonged suppuration and other chronic exhaustive diseases (the waxy and fatty nephritis) is of a bilateral character, from the very outset.

That chronic nephritis may affect one or both kidneys, that the lesions in the two organs may or may not be similar though produced by the same cause, is very evident when the disease is considered in the light of its etiology.

Indications for medical and surgical treatment.——The greatest advantage of a classification of the cases of chronic nephritis, according to their etiology, lies in the aid it affords us in determining the proper therapeutic procedure to employ. Thus: The chronic nephritis due to malposition or ectopy will be certainly cured if the faulty position is corrected. This is clearly shown in Edebohls' cases of nephroptosis with associated chronic nephritis. Nephropexy in these cases brought about a cure of the chronic kidney disease. Likewise the removal of an irrtiating foreign body, *e.g.* stone from the pelvis or substance of the kidney, will result in a cure of the chronic nephritis it has given rise to. The following history is an instance of such an occurrence:

Left renal calculus. Left chronic parenchymatous nephritis; nephrolithotomy; secondary ureterolysoorthosis for persistent kidney fistula. Cure. Schalom B., thirty-four years old, was admitted to Mt. Sinai Hospital, June 24, 1899.

For twenty months he had suffered with pain in the left lumbar region radiating to testicle; these pains came on two or three times a week, and continued for several hours. During attacks of pain, urination was frequent and painful. He had no chills or sweats, occasionally fever. No hæmaturia. Lost some weight in past twenty months. Examination revealed a well-nourished man; conjunctival icterus. Internal organs normal. Kidneys not to be felt.

Urine, alkaline, 1,014, cloudy, contained albumin. Microscopic examination: pus cells, epithelial cells, granular matter, few hyaline casts. Urea 5 grains to ounce. Cystoscopic examination revealed pus descending from left ureter.

August 18, 1899, *nephrolithotomy*. Kidney exposed and delivered on external surface of back.

It was enlarged to one-half again the normal size; surface smooth; a calculus was felt in the pelvis. Kidney was bisected. The cut surface pale, whitish color, very soft consistency, markings indefinite. (Parenchymatous nephritis.) Oxalate of lime stone removed from pelvis; latter contained a few drachms of cloudy urine. Drainage of kidney; closure of rest of section by deep sutures.

Patient reacted well from the operation. Passed sufficient urine; October 3, 1899; *Casts have disappeared from urine;* but pus and epithelia are still present. The kidney fistula persists.

October 12: Cystoscopy revealed clear urine coming from right ureter; from left ureter some pus. Left kidney discharges all its secretion through the fistula in the loin.

October 23: As kidney sinus still persisted, it was decided to again expose the organ, on the supposition that an obstruction in the ureter was the cause of the persistent patency of the fistula. Incision was made in the old scar. *The kidney* was buried in scar tissue; *it was of normal size and appearance. No evidence of disease within it was found.* The ureter was embedded in adhesions and kinked at one point. These adhesions were separated and the kink straightened out. Anchoring of kidney, drainage and closure of abdominal extraperitoneal wound.

November 3: Urine acid, faint trace of albumin, no casts, considerable number of pus cells. Kidney fistula discharges very little.

January 8: Urine normal—acid, no albumin or pus, no casts—kidney sinus closed.

It is to be regretted in this case, that the writer, under whose care the patient was, did not in 1899 possess the skill necessary for ureteral catheterization, and that a bacteriological examination of the urine from the left kidney was consequently not made.

The change in the appearance of the kidney at the two operations separated by a period of about two months, was especially noted; the total disappearance of casts and albumin from the urine at the time of his discharge, further substantiated the cure of chronic nephritis. The patient reported for observation four years later. He has maintained perfect health; his urine is *normal*—the cure of the chronic nephritis was therefore a lasting *one*.

The chronic nephritis due to the toxins of the infectious diseases, is sometimes favorably influenced by operation. Especially favorable are those cases for operation in which the chronic nephritis has not existed too long a time. Thus Harrison was enabled to effect a cure in his three cases of subacute nephritis, following scarlet fever. In the history cited above, in which the chronic nephritis was of eight years' standing and followed an attack of typhoid fever, the albumin and casts disappeared after operation, but reappeared as soon as the patient resumed his customary work. The temporary improvement might, as Rovsing declares, be attributed to his rest in bed. Of the three cases of toxic nephritis reported by Rovsing two were unimproved by operation and one died, from a bilateral hemorrhagic nephritis.

The bacterial nephritides of chronic character are at times favorably affected by operation. Of Rovsing's eight cases, two, in which the disease was unilateral were cured by nephrectomy, one (unilateral disease) by nephrotomy,* two (unilateral disease) by nephrolysis, two (unilateral partial disease) by resection of the diseased portion; and one (bilateral disease) was improved by unilateral nephrolysis.

Edebohls' case (cited above) of bilateral bacterial nephritis in which one kidney was removed and decapsulation performed upon the remaining one, was only temporarily improved, the patient finally succumbing to the disease. The promise of a successful result depends on the character of the infecting organism, its virulence and the type of operation which is employed. Further reference will be made to this latter point.

The chronic nephritides which result from a sclerosis of the interstitial tissue, due to some disturbance in metabolism, have not shown any improvement from operative therapy. The writer knows of no case reported in the literature in which the kidney lesion was associated with arteriosclerosis, myocarditis, emphysema, and cirrhosis of the liver that has been improved by decapsulation or nephrotomy. It seems to be immaterial whether the sclerotic changes are present only in the kidney, or also in other organs. As stated elsewhere, the disease appears to be a *general, constitutional one*, with *local lesions in the kidneys, liver, lungs, heart, arteries*, etc., and could evidently not be influenced by any surgical procedure upon one of these local organs. In the case of the liver an anastomotic circulation may be established to relieve portal congestion and consequent ascites. Were there any indication for an anastomotic circulation in the diseased kidney, this might be established by renal decapsulation; but such an indication never exists. The only condition that could arise, demanding capsule splitting, would be an increased tension within the kidney from shrinkage of the capsule, and consequent anuria.

Rarely, however, in these forms of nephritis, is the shrinkage of the capsule sufficient to call for its splitting; the anuria in these cases is due to degeneration of the parenchyma, which, in turn, is due to the constitutional cause, and which is neither improved nor relieved nor modified nor cured by capsule splitting.

The nephritides, which are secondary to disturbances of the general circulation, *e.g.* myocarditis, valvular and endocardial disease, need no surgical interference—in fact, are made worse by it. If our efforts at regulation and the reëstablishment of the compensation of the circulation by rest, diet, and internal remedies fail, we can expect no good results from decapsulation of the kidneys.

The anæsthetic, the traumatism to the kidneys, and the shock of the operation increase the difficulties of the circulatory organs, and so render the patient's condition worse than before. Likewise the fatty and waxy nephritides that follow upon chronic suppuration, and exhaustive diseases will not be benefited by operation. As long as the primary cause exists, the nephritis will not be improved by any method of treatment. If we remove the cause, and sufficient healthy substance remains, we may expect sufficient hypertrophy of these cells to satisfactorily perform the work of the organ. The chronic nephritis that is associated with new growths of this organ will evidently not be relieved by decapsulation or nephrotomy.

We find, then, that operative interference has been found of value only in those forms of chronic nephritis due to (*a*) malposition of the organ or (*b*) to the irritation of foreign bodies, *e.g.* stones, or (*c*) to the irritation of toxins, or (*d*) to the action of bacteria. It is to be especially noted that even those cases which are not cured by operation are, as a rule, relieved of the severe pain and hæmaturia, which often are the only symptoms that cause these patients to seek the physician's aid.

It is at once evident, from the above facts, that it is our duty not only to establish the existence of a chronic nephritis, but also to ascertain its cause. And, further, to ascertain whether one or both kidneys are involved in the diseased process.

This is possible by careful elicitation of the anamnesis; by thorough physical examination of the patient, and by repeated examinations of the urines. In each case the urine from each kidney should be collected by ureteral catheterization, under strict aseptic precautions, and submitted to a careful bacteriological and chemical examination. Segregation of the urines by any one of the various instruments, besides its uncertainty, is unavailable in these cases, for the segregated urines must pass through the bladder, where they may be infected or contaminated with the bacteria resident therein.

The importance of a careful bacteriological examination of the urine collected by the ureteral catheter is very great. For in the bacterial nephritides the operation that is to be done depends very much on the organism present in the kidney. In some renal decapsulation is practised, in others nephrotomy.

One other fact our examination must elicit, and that is, the combined and separated renal function. Of all the methods, the best is undoubtedly that of cryoscopy. The determination of the freezing point of the blood will indicate whether it is advisable to

*In the latter case Rovsing notes, that the splitting of a kidney, the seat of hemorrhagic inflammation, is a dangerous operation.

undertake any operative interference. With a marked lowering below the normal—say to .60 or lower—the advisability of any surgical attack may be strongly questioned. The kidneys in such cases are already functionating insufficiently, and would very likely be still further impaired in their work, by an operation upon them; an impairment that would probably decide a fatal issue. The determination of the freezing point of the urines gathered separately by the ureteral catheters, would help us to determine the unilateral or bilateral character of the disease and the extent of the involvement of each organ.

The careful investigation into the anamnesis, the thorough physical examination of the patient, and the examination of the separated urines, in all the respects outlined above, is necessary in every case of chronic nephritis that presents itself for treatment. Only in this way can we scientifically and rationally apply the proper therapeutic procedures. And yet in looking over the literature we find only one author who has proceeded in this fashion, and that one, Rovsing of Copenhagen. All the others, Edebohls, Pousson, Bassan, Lenonene, etc., have operated their cases indiscriminately, and their results are of little account in testing the value of surgical interference in chronic nephritis. They have made no distinction, in their cases, between the different causative factors in the production of the disease. They have not collected the separated urines by ureteral catheters, have not made any bacteriological examinations of such separated urines, and have not examined into renal function, either combined or separated. So that we have no data as to the value of surgical therapy in improving the functional power of the diseased organs.

A few words only as to symptomatology. As stated above, neither clinically nor anatomically, nor by examination of the urines chemically, can we differentiate the groups of nephritis from one another. The well-known symptoms of chronic nephritis may be all of them present. Very often the only indications of the disease are severe nephralgia and hæmaturia.

Surgical treatment.—As regards the surgical treatment, we will consider (*a*) The objects of surgical therapy. (*b*) The time at which it is best to advise operation to be done. (*c*) The nature of the operation to be performed.

The aim of all therapy is either to cure radically or to relieve symptoms. As already stated, it is possible in some cases to bring about an entire lasting cure of the chronic Bright's disease by operation. There are certain cases, however, in which the surgical therapy serves only to relieve some of the symptoms of the disease; and especially the pain and hæmaturia. Severe nephralgia and hæmaturia are often the only clinical evidences of the chronic nephritis; they are usually relieved by capsulectomy, though this operation may not in any way influence the diseased process in the kidney.

As to the time at which it is best to advise operation.—Those cases in which the chronic nephritis is secondary to a malposition, or to the irritation of a foreign body, the sooner the position is corrected or the foreign body removed the better. The nephritis in these instances will not be improved by medical treatment, until its cause is removed. In the chronic nephritis of toxic and bacterial origin, internal medication, diet, and good hygiene may bring about a cure. As to its permanency we have as yet no data. Those cases, however, that resist this method of treatment should not be denied the possibility of cure by early operation. If this be too long deferred, the kidney changes become so marked that it is not likely they will be favorably influenced by it. Furthermore, the bad effect of a chronic nephritis upon the heart and body tissues generally makes the resisting power worse, and the patients are much more likely to succumb to the immediate effects of the operation. In the late stages of the disease the patients have become exhausted, the circulation is bad, and the general condition poor, and death is likely to occur from shock or suspension of kidney function.

The following case affords an instance of the inadvisability of late surgical therapy in chronic nephritis: Sarah F., twenty-nine years old, housewife, Austrian by birth, was admitted to Mt. Sinai Hospital, in the service of Dr. Gerster on October 27, 1903. She had been in the hospital for three months about ten years before, suffering with headaches, shortness of breath, œdema of face and hands and feet, and ascites. She had one child five years ago. One other pregnancy in 1901, in which she aborted at second month. When she was five months pregnant with her first child the symptoms of her former illness returned. Three months before her admission in October, 1903, she commenced to suffer with an exacerbation of her disease, marked by dizziness, headaches, poor eyesight, dyspnœa, palpitation; swelling of feet and hands and abdomen.

On admission, physical examination showed her to be pale, anæmic, face swollen, markedly dyspnœic. No uræmic odor to breath or perspiration. There was fluid in both pleural cavities up to level of angle of scapula.

The heart was hypertrophied, especially left ventricle. Soft systolic murmur at apex, transmitted to axilla. Pulse, good quality; regular; increased tension.

Abdomen.—Circumferance 102.5 cm. Contained large amount of fluid.

Liver and *Spleen* normal. Extremities, markedly œdematous.

Vulva œdematous; marked by enlarged hemorrhoidal veins.

Eyes.—Albuminuric retinitis,

Urine.—Acid, albumin, hyalogranular casts.

Kidneys.—Not palpable.

Hæmoglobin, 26 per cent.

The patient came to the hospital to be operated upon for chronic Bright's disease.

Her condition was so poor, however, that it was decided to wait and try to improve the circulation by medical means.

Paracentesis abdominis was at once done: ℥ 155 were withdrawn.

The usual remedies were resorted to, but little improvement followed. The low hæmoglobin count, poor heart's action, and general poor condition, caused us to further postpone operative interference. Dr. Alfred Meyer was asked in consultation to see the patient. He agreed as to the advisability of further medical treatment, with the hope of bettering the general condition and circulation.

December 11: Hæmoglobin 29 per cent. Heart's action better; dyspnœa not so marked; arterial tension not so high. It was thought that as much had been accomplished by internal therapy as could be, and that if ever the patient was to be operated upon, now was the time to do it. We all of us had our grave misgivings, as to her ability to stand the shock of a decapsulation, but the patient and her family earnestly begged that the operation be done.

December 11, 1903: Preliminary paracentesis abdominis. With careful administration of gas and ether the right kidney was first exposed by a lumbar incision. The organ was rapidly delivered. It was of medium size, surface irregular and congested. Consistency moderately hard. Its capsule was

split and stripped off and excised, without difficulty. The operation had taken just five minutes. The patient suddenly collapsed and died of cardiac paralysis. No post-mortem permitted.

Patients in such condition as this one was in, are not fit surgical risks. In them operation is attended with gravest risks to life without hopes of effecting much good.

The following rule seems to the writer to be a fair one:

Establish, first of all, the causation of the nephritis, and so ascertain whether or not the case is at all fit for operation.

Secondly, put the patient for a reasonable time upon internal treatment, with restricted dietary and good hygiene. If improvement is noticed, continue with this treatment; but as soon as the patient reaches a stationary stage or gets worse, then resort to operative treatment without delay.

The Nature of the Operation.—We practise four types of operation for the relief and cure of chronic nephritis, each of which has its indications. These operations are: Nephrolysis, decapsulation, nephrotomy, and nephrectomy.

Nephrolysis, or the breaking down of adhesions between the kidney capsule and the surrounding soft parts, relieves the pain that often attends chronic Bright's disease. This nephralgia, due to a stretching of the kidney capsule, which alone contains the sensitive nerves of the organ, is, as was heretofore stated, frequently the only clinical manifestation of the disease. It is constant in character, deep-seated in the lumbar region, and does not radiate. It is not identical with a true kidney colic. The perinephritic adhesions, by stretching and pulling upon the sensitive capsule, excite the pain. It is doubtful whether one should content himself with the division of the adhesions; as it is not more dangerous to strip off the kidney capsule and excise it, capsulectomy is to be preferred to nephrolysis.

Renal decapsulation, or capsulectomy, was first proposed by Edebohls for the cure of chronic Bright's disease. It consists in stripping off and excising the fibrous capsule of the kidney. The explanation of the good effects of decapsulation is to be found, according to Edebohls, in the formation of new blood-vessels running from the perinephritic tissues toward the kidney cortex. An increased blood supply (hyperhæmatization) is thus produced, in virtue of which the "degenerated parenchyma cells are regenerated, and the inflammatory connective tissue removed by absorption."

As regards the regeneration of kidney parenchyma cells,* Wolff has shown that this never occurs. Healthy kidney parenchyma cells may hypertrophy so as functionally to replace the cells that have become degenerated or been destroyed. But kidney cells once destroyed are never replaced by new ones.

The formation of new blood-vessels which decapsulation is supposed to bring about, must still be regarded as unproven. In a recent discussion before the Genito-urinary Section of the New York Academy of Medicine, Edebohls gave the gross post-mortem findings in a patient that had died four months after capsulectomy, for chronic nephritis. The arteries had been well injected. Numerous newly formed vessels were found passing from the fatty capsule toward the kidney cortex. If this finding is substantiated by others, then these newly formed vessels must be only temporary; for the writer has not found them in a patient upon whom decapsulation and nephrorrhaphy had been done two and one-half years before. The patient's history was:

S. S., twenty-five years old, had been operated upon by the writer two and one-half years before for floating kidney. The capsule was stripped according to Edebohls' method, and the flaps sutured to the lumbar muscles. The wound healed per primam. For two years the patient felt relieved; then owing to emaciation, the kidney again became loose. Kinking of the ureter with intermittent hydronephrosis demanded a second interference. At this second operation especial care was taken to note, firstly, whether the capsule had regenerated over those parts of the kidney from which it had been stripped. And, secondly, the vascular connections between the lumbar perinephritic tissues and the kidney capsule and cortex.

It was found that the kidney was completely enclosed in a fibrous capsule, showing that regeneration had taken place. Secondly, my assistants and I noted that the delivery of the kidney from its remaining fatty capsule was practically devoid of bleeding, and that the stripping off of the fibrous capsule was not attended with the free bloody oozing that usually occurs with this procedure.

This experience would go to show that even though an increased vascularization of the kidney is brought about by capsulectomy, such hyperhæmatization is only a temporary affair. Consequently if the cure depends entirely upon it, then this must be also transient, and recurrences should follow.

The writer does not think that this hypothesis is the correct one. New blood-vessels take time to form—several weeks or even months. Yet the improvement in the symptoms follows very soon upon the operation—from a few days to a week—a period much too soon for new vascular channels to have been established. A more plausible hypothesis for the good effects of decapsulation is the following:

It permits of a freer circulation of blood within the kidney; the arteries bring more blood, the veins carry it away quicker. This increased rapidity of circulation within the organ favors drainage and resorption of inflammatory products; it brings renewed vitality to the degenerated parenchyma cells, and carries off those cellular parts that are dead. The remaining healthy and revitalized cells undergo hypertrophy and so take up the function of those that have been lost. This freer circulation, brought about by decapsulation is not dependent upon a relief of tension within the organ. It may be compared to the better circulation in the thickened edges of a varicose ulcer brought about by multiple incisions.

If we accept the views of Edebohls, that the cure is due to a hyperhæmatization of the kidneys, then we must expect that there should be with the disappearance of the new blood-vessels (as was shown in the writer's case just cited) a return of the chronic nephritis. If, however, we recognize that only the toxic and bacterial chronic nephritides are benefited by renal decapsulation, and that in these cases the good results are owing to a freer circulation within the organ and the opportunity the latter affords for the resorption of degenerated and inflammatory material, and the elimination of the toxic and bacterial material, then we should expect the cure to be a *lasting one*.

The operation of Edebohls has been compared to the Thalma operation for the relief of ascites due to hepatic cirrhosis. This is again a fallacy. The Thalma operation seeks merely to establish a collateral portal circulation. It makes no claim to cure the hepatic cirrhosis.

Nephrotomy acts in about the same way as capsulectomy; it relieves stagnation of the circulation, favors recuperation and hypertrophy of the paren-

* "Über Nierenresectionen und ihre Erfolgen."

chyma cells, resorption of inflammatory and degenerated cells, and drainage, externally of the toxic or bacterial causes of the diseases. Nephrotomy does this even better than decapsulation; but it has its disadvantages. Thus, it damages and renders functionless a portion of secreting tissue, thereby favoring the uræmic state; it is especially to be avoided then in bilateral chronic nephritis.

Again, nephrotomy opens up a large raw surface in the kidney, which may become infected either from the bacteria already resident within the kidney or through other channels, and so favors destruction of the organ. Nephrotomy therefore is only practised for exploratory purposes, or for drainage of disseminated abscesses.

Nephrectomy is, of course, only applicable to unilateral disease, and that only when the affected organ is so far destroyed that its removal is demanded.

The writer has broadly attempted to fix the indications for the rational surgical or medical treatment of chronic nephritis. As more material conducted with exhaustive methods of examinations is accumulated, we may, from its study and analysis, be able to narrow down or widen out our indications for the employment of the one or other of these methods of treatment.

923 Madison Avenue.

A FEW WORDS CONCERNING RADIUM.*

By HENRY G. PIFFARD, M.D., LL.D.,
NEW YORK.

Emeritus Professor of Dermatology, New York University; Consulting Surgeon, City Hospital; Fellow of the New York Academy of Sciences, etc.

In view of the vast amount of misinformation concerning radium that has been circulated not only by the lay press, but also by the medical, it seems to the writer that a plain statement should be made of the few facts that appear to be positively determined; that some erroneous and misleading assertions should be controverted; and that the lines of research to be undertaken with special reference to the utilization of radium as a therapeutic agent should be indicated.

According to the researches of Rutherford, Crookes, Ramsay, Mme. Curie, and others, radium emits both "Radiations" and "Emanations." The radiations or so-called rays are not simple and uniform in character, but are a mixture of rays exhibiting widely different physical phenomena, and by Rutherford have been called *alpha*, *beta*, and *gamma* rays. The *alpha* rays appear to be electrons, carrying a charge of positive electricity slightly deviable by the magnet. They constitute the largest proportion of the total, but possess but little penetrative power. Glass presents an almost insurmountable barrier to their passage.

The *beta* rays are electrons carrying a negative charge and are strongly deviable by the magnet, but in a direction opposite to that of the *alpha* rays. They exist in a comparatively smaller proportion than the *alpha* rays, but possess a greater penetrative power. They appear to be similar to, if not identical with, the "rays" projected from the cathode of a Crookes' tube when excited by a suitable electric current.

The *gamma* rays exist in a much smaller proportion than the others, are non-deviable and possess penetrating power to a high degree. They exhibit phenomena similar to, if not identical with, the Röntgen, or *x*-rays.

The so-called radio-activity of radium is due to the combined influence of the *alpha*, *beta*, and *gamma* rays. The first two are undoubtedly material particles projected with great velocity. The *gamma* rays, on the other hand, are not material particles, but undulations of exceeding small wave-length, and correspondingly high frequency.

The *emanations* of radium differ wholly in character from the radiations above mentioned. The emanation is a gas continually given off by radium, and may be collected in a separate receptacle and its properties examined. After it has been separated for a few days from the original radium it exhibits properties that heretofore had been associated with element helium (Ramsay). This emanation is not only of itself radio-active, but possesses the power of exciting radio-activity in other bodies in its immediate neighborhood—that is, it confers on them the ability to emit Becquerel rays similar in character to those of radium. This induced or secondary activity is not permanent, but rapidly decays and in a few days leaves but hardly appreciable traces. These emanations of radium will not pass through glass.

Radium, as is well known, is obtained from pitchblende, the mineral that for many years has been the commercial source of uranium. While experimenting with a preparation of uranium, M. Henri Becquerel† made the accidental discovery that the substance emitted radiations capable of affecting the silver compounds contained in the photographic film. An examination of pitchblende revealed the fact that it was also radio-active and even to a higher degree than uranium. Mme. Curie then took up the search for the original source of the radiations, and operating on Bohemian pitchblende finally succeeded in producing compounds of varying degrees of activity, which are assumed to be more or less pure preparations of the hypothetical element to which the provisional name of *Radium* has been given.‡ For more than a year these preparations have been placed on a commerical basis, and can be obtained at prices varying with their supposed purity or radio-activity. A preparation rated at "7000 activity" was that many more times as active as uranium, and so on for the asserted degrees of higher activity. The *fact* of radio-activity is readily ascertained by the aid of a photographic plate, but the *degree* is not so readily determined. The process in vogue is an electrical one, depending on the ionization of air, and is assumed to be reasonably accurate so far as the lower activities up to possibly 100,000 are concerned; beyond that its readings are somewhat doubtful, and cannot be depended on at all in connection with the activities rated at one million or more. These later being more or less accurate determinations deduced from entirely different data.

The various preparations of radium in general circulation are self-luminous—that is, they shine in the dark. The intensity of this luminescence, however, bears no ascertained ratio to the radio-activity of the specimen under examination. Whether absolutely pure radium (not yet produced) or pure radium bromide are self luminous I have not been able to satisfy myself. On theoretical grounds it seems to me that pure radium, emitting only the *alpha*, *beta*, and *gamma* rays, should not be luminous, as neither of these forms of radiation or undulation are singly visible to the eye. Until we have more certain information on the subject it is a fair presumption that the observed luminescence is due to

*Read at a meeting of the New York Academy of Medicine May 19, 1904.

†Born 1852, son of Edward Becquerel, whose treatise, "*La Lumière, ses causes et ses effets*," Paris, 1867, was studied, and many of the experiments detailed therein, repeated by the present writer, more than thirty years ago.

‡Mme. Curie first discovered "polonium," and later, in collaboration with M. Bemont, discovered radium.

the action of the radium on some of the impurities present, notably barium, with which the radium preparations, except those of the very highest purity, are constantly associated.* Possibly it is due to the fluorescence of nitrogen in the tube.

The luminescence of a radium preparation of medium or low activity can be notably increased by mixing with it certain substances in which it excites fluorescence. This in no way increases the activity of the preparation—in fact, it tends to debase it.

Among the interesting phenomena associated with radium, is its ability to excite fluorescence and even phosphorescence, in certain other bodies, notably zinc sulphide, strontium sulphide, barium platinocyanide, willemite, diamond, kunzite, etc. If a tube, of say 20 M. activity, be brought into immediate proximity to any of these, in a dark room, a faint glow will be perceived (fluorescence), and in some cases this will persist after the withdrawal of the radium (phosphorescence). The effect, however, is far inferior to the fluorescence or phosphorescence developed in the same bodies by the ultraviolet rays as neither the green of willemite or the red of calcite are appreciable. A tube of 300 M. activity brings out the green, and a faint pink in the calcite.

A large crystal of kunsite 8 mm. thick, and a block of rock salt 15 mm. thick, are both transparent to ordinary light but both are opaque to *x*-rays, while the kunsite is also opaque to ultraviolet rays. Both specimens, however, are transparent to the luminescence of radium (20 M. activity).

During the past few months a few gentlemen have given the profession and the public to understand that they could render water, salt solutions, and other media radio-active, by simply immersing therein a glass tube containing radium, and which solution then became a potent agent for good in the treatment of various maladies. The importance of this discovery(?) if true, would be inconceivable, but, so far as I can learn, the gentlemen referred to are the only ones who have succeeded in accomplishing this feat. Personally I experimented in the manner indicated with radium of 7 M. and 20 M. activity with negative results. Dr. Robt Abbe, with a tube containing 100 mg. of 300 M. activity, also failed to find any evidence of induced radio-activity in the solutions in which the tube was immersed. Dr. Geo. B. Pegram of the Department of Physics of Columbia University has stated to me that his efforts to produce radio-active water by the means referred to were unproductive of results; and so far as I am aware no physicist or other competent observer has succeeded in bringing about this marvelous phenomenon.

Mme. Curie in her "*Recherches sur les substances radio-actives*" (Paris, 1903), states that if a receptacle containing radium, *open at the top*, be placed in a confined space together with other substances, plates of metal, etc., these will all, in a day or so, become radio-active. If, however, the experiment is repeated with the vessel containing the radium *closely stopped*, the results will be negative.†

In view of the foregoing, it seems to me that the gentlemen referred to owe it to themselves and to the profession to demonstrate publicly their ability to perform the feat they have described or else admit that the statements were made on insufficient evidences or were perhaps evolved from their inner consciousness. Until this is done I confess I prefer to accept the negative evidence of competent physicists. A recent experience bearing on this point was for a short time somewhat disconcerting. I took a piece of pitchblende, laid it on a protected plate, covered it with a watch glass, and on the same plate laid a tube of 20 M. activity also covered with a watch glass. The radium tube was removed after two hours, but the pitchblende was left in position for thirty-five and one half hours. The plate was then developed. In this experiment I hoped to demonstrate the fact that the pitchblende, being free, would endow the inner surface of the glass with induced radio-activity, which in turn would affect the photographic plate; while the other wine glass would be free from induced radio-activity. On developing the plate, however, it was manifest that both wine-glasses were well coated with radio-active matter. This for a moment seemed to prove that the emanations could go through the original glass tube in which the radium was confined. An examination of the tube, however, with a good lens, revealed a minute perforation in the tube, the result of an air bubble in the glass. Since then I have heard of several other gentlemen who have met with a similar experience.*

If one really desires to prepare radio-active water, it can be readily accomplished by simply dissolving radium in the water. What the physiological effect of such a preparation taken internally or applied externally would be, no one, so far as I am aware, has as yet ascertained. Radio-active water may also be obtained by exposing the water or any other fluid to the emanations of radium contained in an open vessel. In a few days the water will have acquired all the induced radio-activity of which it is capable, but the radium preparation will in equal measure have lost its own radio-active properties. These, however, may be regained if the radium be thoroughly dried, then heated, and finally replaced in a tight glass tube. In a month or so it will have recovered its former activity. If the radio-active water be placed in a vial and hermetically sealed the radio-activity will slowly decay, and at the end of a month or so it will virtually have disappeared.

Unfortunately, imperfect or ruptured tubes have been used much more frequently than is generally known, and this has been ascertained to arise from two quite different causes:

(1) The emanation that is constantly form-

*As early as 1603 Vincenzo Casciorolo of Bologna (Italy) discovered the phosphorescence of sulphide of barium, and in 1663 Robt. Boyle discovered the fact that certain diamonds would shine in the dark after exposure to a strong light. (E. Becquerel, *op. cit.*)

†"Si l'on repète l'expérience précédente avec l'ampoule fermée on obtient aucune activité induite." Recherches, etc., p.106.

*Since the foregoing was written, Dr. M. Metzenbaum has published the following in the *Cleveland Medical Journal*, May, 1904:

"It has been stated that if a sealed tube containing radium of high activity be suspended in a normal salt solution, and solutions containing various drugs, that these solutions become radio-active and are capable of affecting photographic plates.

"It has further been intimated that if radium has a therapeutic value, then these solutions which have been rendered radio-active might likewise have a therapeutic action, and since solutions can be taken internally, the possibilities of these radio-active solutions might be of considerable value.

"In view of this fact, I conducted a very large series of experiments, from which the following negative results have been obtained:

"Two tubes of radium of 1,000,000 activity, each containing 5 milligrams, and two other tubes of lesser activity, each containing 50 milligrams, were placed in a normal salt solution and remained there for ten days.

"This solution was placed in test-tubes of very thin glass and in the small vials in which hypodermic tablets are contained. These were then strapped with adhesive plaster on to the film side of photographic plates. Some of the plates had first been covered with black paper.

"These tubes remained from a period of twenty-four hours up to twenty-one days, and in no case was there the faintest sign that the photographic plates had been affected."

ing being (so to speak) one of the catabolic or disintegration products of radium, is a gas, and as it forms it exerts pressure on the walls of the tube. This pressure increases with time and may finally burst some specially weak portion of the glass (location of an air bubble, etc.) and thus escape. Accompanying this escape there will be a deterioration of the activity of the radium, which will not regain its former power until the perforation has been closed. This accident appears to be unavoidable, and there is no means, so far as I know, by which it can be guarded against.

A remedy for this will, of course, immediately suggest itself; namely, the transfer of the radium to a sound tube. Glass utterly absorbs the alpha radiations, and in a great measure also absorbs both the beta and the gamma. In consequence of this, the efficiency of the preparation is very greatly impaired; that is, from a tube of given activity one is able to utilize only a portion of the activity. A number of substitutes for glass have been tried, and among them aluminum appears to have found most favor. An aluminum tube devised by Mr. Hugo Lieber appears to fulfil the required conditions more fully than any I have seen. The metal is .004 inch in thickness, and radium in such a tube displays a higher activity than it did in the original glass tube from which it was transferred. Furthermore such a tube will not rupture from the pressure of the gaseous emanation. This is due to the fact that when the pressure becomes sufficiently high, a portion of the emanation is forced through the pores of the metal. The loss of emanation is to be regretted, but it can be remedied in a measure by having another safety tube of silver into which the aluminum tube is fitted, with a closed joint, and in which it should be kept except when in actual use.

(2) The second cause for the perforation of a glass tube is the increase of electric potential within the tube. Just as soon as this becomes sufficiently high the electricity sparks through, as not infrequently happens in x-ray and other vacuum tubes.

To guard against this accident I would propose what appears to me a very simple and effective remedy, namely sealing a small piece of platinum wire into the glass tube. It need only project a very short distance into the tube, and externally may be flush with the glass.*

In view of the foregoing, it would certainly seem wise for the operator from time to time to test his tubes for punctures. This can be readily done with the aid of a photographic plate. To do this: take a plate protected from the light by the customary non-actinic envelopes and lay the tube on it for an hour or more, then move the tube to another part of the plate and cover it with a large watch glass or Petri dish and expose for an equal length of time. The plate is then developed and the evidence of induced radio-activity, if present, will be readily perceived.

Radio-activity, using the term in a broad sense, is a phenomenon that in a minor degree is recognizable in connection with a large number of substances and conditions. The air is feebly radio-active, as also a tea-kettle of boiling water, as Captain Abney has photographed one (in a dark room) by its own infra-red radiations.

In a more restricted sense, however, it is a property produced by a few elementary substances which, without apparent access of energy from without continually throw out radiations, and display manifestations that constitute one of the most interesting scientific problems of the present day. The substances specially endowed with these qualities are, uranium, thorium, actinium, polonium (?) and radium, and the ores and minerals with which they are associated†

The radio-activity of these substances manifests itself by its chemical or actinic effects on a photographic plate, by its ability to ionize gases, including ordinary air, and by its power of producing fluorescence and phosphorescence in certain minerals and other substances. These several manifestations of activity do not pertain alone to radium and the other substances named, but some of them are in evidence under divers other circumstances. I, therefore, think it well to here compare the radio-activities of radium with some of the phenomena dependent on other sources of radiant energy:

(1) SUN-LIGHT.		
Affects a naked photographic plate, but not one protected by an opaque shield.	Excites phosphorescence in polysulphide of calcium and a few other substances.	Does not ionize the air or other gases, and, consequently, will not discharge an electroscope when either positively or negatively electrified.
(2) 50 CANDLE-POWER INCANDESCENT.		
Same as above.	Causes slight phosphorescence of polysulphide of calcium—no effect on willemite or calcite.	Does not discharge the electroscope.
(3) 50 CANDLE-POWER INCANDESCENT WITH BLUE BULB (MININ LAMP)		
Same as above.	Same as above.	Same as above.
(4) ARC-LIGHT WITH CARBON ELECTRODES.		
Same as above.	Causes fluorescence and phosphorescence in many substances.	Ionizes the air slightly, and discharges electroscope slowly when charged negatively, but not when charged positively.
(5) ARC-LIGHT WITH IRON ELECTRODES.		
Same as above.	Fluorescence and phosphorescence more intense than the above.	Ionizes the air more rapidly and discharges a negatively-charged electroscope more promptly, but does not affect one positively charged.
(6) ULTRAVIOLET RAYS FROM HIGH TENSION CONDENSER SPARK.		
Same as above.	All fluorescence and phosphorescent phenomena greatly intensified, certain calcites fluoresce bright red.	Discharges negatively-charged electroscope instantly, but does not affect one positively charged. The high tension condenser spark contains rays other than ultraviolet that will discharge electroscope bearing a positive charge. These rays are largely absorbed by quartz.
(7) X-RAYS.		
Affects photographic plate, although protected by opaque screens.	Fluorescent and phosphorescent phenomena much less pronounced and does not affect all of the radio-responsive substances in the same manner as the ultraviolet rays.	Discharges electroscope, whether charged negatively or positively.
(8) RADIUM.		
Same as above.	Phenomena much less noticeable, perhaps due to the inability to procure a mass of radium that will give a sufficient volume of radiations.	Instantly discharges electroscope, whether charged negatively or positively.

When we compare the manifestations of radium with those of the x-ray we are immediately struck by the similarity between them.

In the first place they are both capable of penetrating many substances that are opaque to the

*Since this was written Prof. Chas. Baskerville has informed me that he had already adopted this expedient. This is such a simple remedy that probably others also have made use of it.

†It is more than possible that polonium is not an element, or gifted with potential continuous activity. It may be simply bismuth which has acquired temporary activity from its close association with radium. By some it is thought to be radio-active tellurium, or it may simply be one of the disintegration products of radium (Rutherford). Quite recently Professor Baskerville has determined the presence of two new elementary substances in commercial thorium, and has ascertained that they are radioactive, while the purified thorium is not. He has given the names carolinium and berzelium to these elements.

luminous rays of either natural or artificial sources. They both induce fluorescence and phosphorescence In practically the same class of radio-responsive bodies, though the manifestations of this property differ widely in degree rather than kind. Their behavior to the electroscope is relatively the same. When we study the characteristics of the two more intently, and from the standpoint of the physicist rather than that of the casual observer, a still closer resemblance will be noticed. In the ordinary *x*-ray tube we have a positive and a negative electrode and also a target, which at the same time may be the positive electrode or it may be wholly independent of it. The radiations (negative electrons) from the cathode, which is usually curved and focussed on the target (anti-cathode), are hurled against it with astounding velocity. These electrons (cathode rays) are material bodies (not undulations), or rather, perhaps, material substances charged with negative electricity. When they encounter the target three things happen: (1) a portion of the energy is transformed into heat; (2) another portion of energy gives rise to radiations or probably undulations—the true *x*-rays—which leave the target in straight lines and pass outward without swerving or capability of being swerved, until they encounter bodies capable of wholly absorbing them. (3) What is left of the cathode rays are reflected outward, where in great, perhaps in greater, part they are absorbed by the glass of the tube, rendering it fluorescent. A part of them, however, pass out (Sir Oliver Lodge) and dissipate their energy on bodies they encounter in their path. These radiations can be swerved or deflected from their course by means of a magnet. The radiations from the anode of the tube, being negligible from the practical standpoint, and, so far as known, unable to escape from the tube, have not been so fully studied.

An examination of radium develops the fact that here also we have three kinds of radiation, the so-called *alpha*, *beta*, and *gamma* rays. The first are positive electrons, the second negative electrons, and the third probably undulations of exceeding short wave length, and with almost unmeasurable frequency. The *alpha* rays are masses of matter of about twice the size of the hydrogen atom; the *beta* rays are also masses of matter of sub-atomic size and having a bulk of about one-thousandth that of the *alpha* rays. The *gamma* rays are presumably not masses of matter but etheric undulations.

The *alpha* and *beta* rays are in continual motion, but the first are sluggish in their movement, their velocity not exceeding sixteen thousand miles per second. The *beta* rays are pretty active and lively particles with a velocity ten times that of the *alpha*. The penetrating power of these several rays is likewise not the same. The *alpha* rays possess this power to but a limited degree, being almost wholly absorbed by the glass walls of the ordinary radium tube. The *beta* rays will traverse a limited thickness of glass or aluminum, one-half millimeter of the latter absorbing about 50 per cent. of the activity; while the *gamma* rays will traverse one hundred times that thickness with no more loss. The velocity of the *beta* rays exceeds that of the cathode rays, as does also their penetrating power. The frequency of the *gamma* rays exceeds that of the *x*-rays and they also surpass them in penetrating power.

The lesions of the skin that follow a too strenuous application of radium are similar in character to those that are encountered after an excessive application of the rays from a Crookes' tube. Williams has shown that the lesions are in the main due to the *beta* rays of radium, while the reactionary effects of the *x*-ray tube are due, I believe, chiefly, if not wholly, to the cathode and not to the *x*-rays.

If we were to draw an analogy between these two sources of energy we might compare the *x*-ray tube to a good road-horse, radium to a thoroughbred, or we might say that radium is a transcendentalized pocket edition of the *x*-ray.

In buying radium certain precautions should be taken. In the first place I would advise that the purchase be made (when possible) direct from the manufacturers' accredited agent.*

And second, that the tube be tested as to its ability to produce induced radio-activity. If it should do so, examine it carefully for some defect, and if found, have the salt transferred to another tube, as any escape of the emanation temporarily degrades the activity, which, however, becomes fully restored in three or four weeks if again enclosed in a perfect tube. The actual radio-activity of any given specimen—that is, the activity on which the sales price is based—can be determined only by opening the tube and testing the naked radium by means of an electrometer, but a rough estimate of the efficient activity of an unopened tube can be made with the aid of an electroscope. A suitable electrometer with the necessary accessories is a complicated and expensive piece of apparatus and requires the skill of a trained

*Radium coming from the laboratories of the Curies of Paris or Sthamer of Hamburg can be relied on as possessing the activity that is claimed for it. This, however, is distinctly not true of radium coming from at least one other source. Some months since, the writer purchased a tube of radium, stated by its maker to be of 40 M. activity and labelled "höchst concentrirt" (highest concentration). On testing the tube with the electroscope I found it to be of very low activity, discharging the electroscope much more slowly than a tube of Curie 7 M. I then tested it photographically in comparison with a tube of 1 M. Curie and found it slightly inferior to it. On reporting my findings to the importer, he sent a tube from the same lot to Paris to be tested, and it was then reported to be of less than 1 M. activity, thus confirming my earlier determinations.

The detection of radio-activity with a suitable electroscope takes but a moment's time, and will enable one to form a rough estimate of the degree of activity, especially within the range of the lower activities. It also enables one to test the various lamps for ultraviolet radiations.

Not finding on the market, either here or abroad, an electroscope that conveniently met my requirements, I designed the one here shown (Fig. 1).

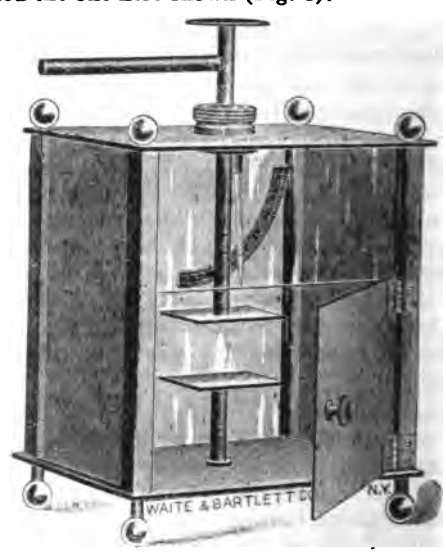

FIG. 1. The author's electroscope.

With the aid of an electroscope the writer recently discovered some radiations (possibly of therapeutic value), of which I find no previous account (see *Journal of Cutaneous Diseases*, June, 1904).

It should be distinctly understood that it is not possible accurately to determine with an *electroscope* the higher grades of activity in uranium units; for this purpose an *electro-meter* must be employed.

physicist to manipulate it properly and arrive at an accurate determination. I possess neither the instrument nor the skill. A little practice with an electroscope, however, will enable anyone to note any marked discrepancy between the assigned activity and the performance of the tube. This instrument is inexpensive and can be obtained in the market in different forms, and enables one in a moment to differentiate bodies that are, and that are not, radio-active and roughly to judge the value of the various uranium ores (chiefly pitchblende, carnotite, and autunite) that are being searched for and found on our own continent. It also enables one to roughly estimate the richness in ultraviolet of the radiations from different luminous sources.*

For many years uranium has been employed in the manufacture of Bohemian glass, and was obtained from the Bohemian deposits of pitchblende. The residue left after the extraction of the uranium was deemed of little value until the discovery was made that it was the richest source of radium, and nearly all of the radium commercially produced has been obtained from these accumulated residues which are now exhausted. As the glass industry is of more importance to Bohemia than radium, the Austrian Government will not permit the export of native pitchblende to France or Germany, and the only available present source of radium is the uranium residues that are obtainable from the current manufacture.

The extraordinary demand for radium and the now very limited supply, has naturally led to a marked advance in price. A certain quantity of radium for which $80 was charged in January is now held at $300; and for another for which $35 was asked in January now (May) costs $150.

Europe does not appear to have any other radiferous deposits of sufficient richness to pay for working, and the present hopes of supply center on the asserted discovery of pitchblende and carnotite in our Western States and elsewhere. I have examined carnotite from Colorado and from Utah, which possess but slight activity, but have obtained specimens of Colorado pitchblende that possessed activities ranging from two to four as compared with uranium.

The complete physical history of radium has by no means as yet been fully worked out, and physicists themselves are not wholly agreed as to the observed facts, and less so as to some of the theoretic questions that are involved. It has been, therefore, no easy task for the present writer to sift the mass of material at his command and obtain even a fairly clear idea on the subject, and it would be surprising, indeed, if here and there some inaccuracy had not crept in.

When we turn from the physical to the therapeutical investigation the task of arriving at a fair approximation to the truth is still more difficult. The reports from different observers are in most instances of little or no value as guides to the surgeon who is about to make his first essays with this remarkable substance, and to-day we are but little better off in this respect than we were a year ago, when the present writer expressed himself as follows:

"Knowing the powerful destructive effects of these radiations on normal tissues, we are naturally fascinated by the thought that we may be able to utilize their powers for the modification of the carcinomatous and lupoid processes, and thus avoid the inconvenience and expense of the present *x*-ray technique. There is, however, one serious difficulty in the way, namely, our inability to determine the precise amount of radiant energy exerted by any given preparation. In other words, we cannot exactly dose the application. Great as is the difficulty in dosing the *x*-ray exposure, it is vastly greater when we undertake to utilize the radio-active substances that at present are furnished commercially." (MEDICAL RECORD, March 7, 1903.)

History has shown that wherever a new or powerful therapeutic agent has been introduced, the early reports of its use are extremely favorable, especially from those who appear to be anxious to have their names connected with it as being among the first to use it. More conservative operators reserve their opinions until they have accumulated a wider experience and have learned not only the advantages but also the limitations of its therapeutical action.

The pathogenic effects (wrongly termed "physiological action") of a drug should be studied and understood in advance of its therapeutic use, and in like manner the pathogenic action of radium should be investigated prior to its application as a curative agent. As a matter of fact the pathogenic action of radium was discovered early, and by accident, and by physicists, and not by physicians. This much we know: that when radium is applied to the skin it may simply produce a temporary hyperæmia, or, on the other hand, an extensive necrosis followed by an intractable and long enduring ulcer. The different degrees of reaction or of destructive effects depend directly on the dosage, modified by the specific resistance of the part operated on. It has been further noticed that the character of the reaction closely resembles that which follows the use of the *x*-ray tube, which, of course, was to be expected, when we consider that the physical agencies involved are similiar if not identical.

The most unsatisfactory problem in connection with radium to-day is that which concerns dosage. Thus far our knowledge of radium will permit us to say, that on the one hand we can produce a rapid and thorough destruction of so much of the lesion as is within the immediate sphere of influence of the preparation (if a strong one); or on the other hand we may in some instances slowly bring about its disappearance by bringing into action certain physiological processes (local leucocytosis, etc.). This again is simply a question of dosage.

Radium affects the photographic film and also the electroscope and electrometer, but it is by no means certain that the radiations that are most active photographically are the ones that most strongly ionize the air in the electrical apparatus, and it is still less certain as to which is the more efficient in its action on the human tissues. As the photographic film and the electroscope give but rough approximations as to the radio-activity of any given preparation, reliance is placed on the more accurate determinations of the electrometer. This determines the actual radio-activity of the *naked* radium, and is ascertained in advance and before sale by the manufacturer. The *efficient* radio-activity is quite another thing and will depend largely on the nature of the material (glass, aluminum, celluloid, mica, etc.) in which the radium is contained. As the actual *radio-activity* as given by a reliable manufacturer can in general be relied on, it only remains to determine the actual *efficiency* in the manner above indicated. The unit of radio-activity generally adopted is that of one gram of metallic uranium, but the efficiency of a given tube will depend on the radio-activity by the above standard multiplied by

*"The electroscope is the best test you can have for certain kinds of radiation."—Sir Oliver Lodge, *Archives of the Röntgen Ray*, May, 1904.

The presence of less than $\frac{1}{10,000}$th of a grain of thorium can be detected with the electroscope (Rutherford).

the quantity of radium preparation in the tube, be the same more or less than one gram, minus the absorption by the container. If we indicate the radio-activity of a given preparation by A, and the absorption of energy by the container by x, the actual efficiency by E, we can readily construct the equation E = A-x. Now, the efficiency being the same, the reaction will not necessarily be the same for any two persons or for tissues of a different character, and as what might be termed the physiological inertia varies with each person and with each tissue, it constitutes in the main the unknown factor and may be represented therefore by X. If two applications be made, say one of five minutes and the other of ten, we would naturally expect (other factors being the same) a more intense reaction from the latter, and such we find to be the case. As the factor X, however, does not necessarily remain the same, the ten-minute application cannot be depended on to have exactly twice the effect of the other. With the data given above, however, we can readily construct a temporary working equation in which R will represent the reaction and M the mass of the radium employed expressed in grams, and T the time in seconds.

This will give us:

$$R = \frac{E \times M \times T}{X}$$

I do not for one moment suppose that, in actual practice, the equation will work out as simply as it is here expressed; but it certainly contains elements that should be borne in mind, and should be recorded in connection with reports of clinical experience. The equation as given assumes that 100 mg. of the 100 M. activity would equal in effect 10 mg. of the millionth. I do not know whether any one has ascertained whether such is the case or not, but it is a line of inquiry that should be taken up. One thing, however, is certain, the mere statement that an experimenter has or has not cured a case of cancer, lupus, or anything else with radium without at the same time giving as fully as possible the data called for in the above equation, is of little value to anyone but the operator himself. It is clearly of little value to anyone reading the report.

In the foregoing pages I have endeavored to present in the fewest words an outline of the principal facts that have been ascertained concerning radium. The student, however, who desires more comprehensive information; and the practitioner who wishes to obtain a good working knowledge of the subject is strongly advised to consult the following monographs and articles: Mme. Curie "Recherches sur les Substances Radio-actives," Paris, 1904; Soddy, Lectures on Radio-activity in *The Electrician*, October, 1903, to February, 1904 (announced for early publication in book form); Sir Olive Lodge, "Lectures to Medical Practitioners on Physics Applied to Medicine," now being published in the *Archives of the Röntgen Ray;* Foveau de Courmelles, "Le Radium et les Corps Radio-actifs," *Revue Internationale de Thérapie Physique*, November 1, 1903; Halkin, "Über den Einfluss der Becquerelstrahlen auf die Haut," *Archiv für Dermalogie und Syphilis*, 1903; Scholtz, "Über die physiologische Wirkung der Radiumstrahlen und ihre therapeutische Verwendung," *Deutsche medizinische Wochenschrift*, January 14, 1904; Rollins, "Some Principles Involved in the Therapeutic Applications of Radio-activity," *Boston Medical and Surgical Journal*, November 12, 1903; Articles by Williams, *Medical News*, February 6, 1904; and *Boston Medical and Surgical Journal*, February 25, 1904; J. Mackenzie Davidson, *British Medical Journal*, January 23, 1904; Plimmer, *Lancet*, April 16, 1904, and Darier in the same issue; Bergonié, "Le Radium au Point de Vue Médical, etc.," *Archives d'Élecricité Médical*, February 25 and March 10, 1904; Goodspeed, "The Trend of Modern Thought on the Sub-atomic Structure of Matter," *Archives of Electrology and Radiology*, March and April, 1904; Rutherford, "Radio-activity," Cambridge, England, 1904. HYDROCELE OF THE CORD; REPORT OF CASES.*

By A. JACOBY, A.B., M.D.,
NEW ORLEANS, LA.
VISITING SURGEON TO CHARITY HOSPITAL; CHIEF OF CLINIC TO CHAIR OF SURGERY, NEW ORLEANS POLYCLINIC.

My reason for reporting this subject has been actuated by the fact, that it has been brought so notably to my attention by the several patients who have presented themselves to my clinic lately. The matter has also been forcibly impressed upon me by the reason that all three cases had been referred to me as ones of oblique inguinal hernia, when neither showed any evidence of this complication. It is not at all surprising that it should be coupled with hernia, however, since the external evidence resembles very closely a scrotal hernia, because the tumor is continuous into the inguinal canal, and is reducible. These are the first cases that I have seen for some time, and I believe that the condition is infrequent or unrecognized, so that it is worthy of some remarks.

Indeed, the subject does not seem worthy of much consideration by our textbooks, and the manner in which it is discussed would lead one to believe that it is either rare or of slight moment. There seems to be little literature on the subject, and yet cases are not infrequently seen, especially in the baby clinics.

Hydrocele of the cord is due to a serous exudation in an unobliterated portion of the processes vaginalis. It may be either encysted or funicular; in the former the funicular process is obliterated above and below, but is open between these two points, in which fluid collects, while in the latter the funicular process is closed only below, and in raising the pelvis the fluid flows back into the peritoneal cavity. In some cases they are circumscribed, while in others they involve the entire length of the spermatic cord or inguinal canal. They may communicate with either the cavity of the tunica vaginalis propria or with the abdominal cavity. In the three cases, to which I shall refer, they communicated with the abdominal cavity, so far as I could judge, and, therefore, belong to the funicular variety.

There does not seem to be any definite cause for this condition. The most frequent is trauma, while gonorrhœa does not seem to play any great part. All three cases referred to the fact that they did heavy lifting, and two stated that they felt that this trouble had developed after straining to raise some heavy article. In one case, the patient had not noticed the trouble until he had an attack of gonorrhœa, to which I could not attribute the cause. None of them had remembered receiving any blow in this region. They were all young, and had noticed the swelling only a short time before coming to the clinic.

The diagnosis does not seem difficult, and it appears strange that a previous diagnosis of hernia should have been made. The tumor is usually soft, elastic, and translucent, and most frequently

*Read at a meeting of the Orleans Parish Medical Society on March 26, 1904.

found on the left side. Fluctuation is very evident; it readily pushes up into the inguinal canal, and can be well outlined. As a rule, judging from my experience entirely, the fluid gravitates back into the inguinal canal or abdominal cavity, when the patient is made to lie on his back, and the pelvis raised, whereupon all evidence of a tumor disappears. Unless the hernia exists as a complication, we usually find the external ring of normal size, and slight or no impulse of the intestine upon coughing.

The three boys, I may say, who presented themselves to my clinic, two of whom were eighteen and one seventeen respectively. The one who was seventeen had a marked double varicocele, and the hydrocele, in this instance, was of the right cord. He had been sent by his physician from the country to be operated upon for hernia. Dr. Parham concurred in the diagnosis of hydrocele of the cord and suggested operation, to which the patient refused, after learning the real nature of his trouble. He had never been sick in his life, nor had he had any venereal disease.

The other two, who were eighteen years each, had hydrocele of the left cord, and were referred to the hospital for confirmation of a previous diagnosis of hernia, and for suggestion as to a line of treatment. One denied ever having had any venereal disease, but said, on the contrary, that he had always been well. Both he and the previous patient reported remarked that they had noticed this swelling, or had felt something give way after exerting themselves in lifting some heavy article. The other patient, however, had developed acute gonorrhœa on December 25, 1903, but did not notice this enlargement until January 4, 1904. He was then treated for gonorrhœa in the venereal clinic, and later referred for further attention to me. Though in this clinic a diagnosis of hernia had been made, I could only determine a slight enlargement of the external inguinal ring, and a slight impulse of the intestine against the index-finger when the patient coughed.

The treatment may be divided into three classes: First, the use of a truss; second, removal of the fluid, with or without the injection of an irritant; third, the radical methods (*a*) incision and drainage, (*b*) excision of the sac, (*c*) incision of the sac, everting it, and suture.

The first is a very questionable procedure, except for infants, to be used only in the funicular form, and, even then, I doubt of its efficacy. The second is sometimes satisfactory when combined with a truss, but there is very much objection to the injection of an irritant. Indeed, the danger of sloughing, the entrance of some of the irritant into the abdominal cavity, or a disastrous effect upon the cord, is sufficient to make one hesitate in its use. The third methods are really the only logical ones, as they mean the positive removal of the cause. Incision and drainage is not very satisfactory, as it means an open wound for some time, the risk of infection, and much time lost to the patient. The removal of the sac is not difficult, as it can be easily released from the cord, and most of it excised without much trouble. Dr. Parham had advised the other method, which seemed more feasible and rapid in execution. He suggests laying the sac wide open, folding it behind the cord, and passing a few sutures through it, thus making a continuous line with the mesenteric border of the cord, an operation very similar to that of Doyen for hydrocele of the tunica vaginalis testis.

It is to be regretted that the three patients refused to be operated upon, when they learned the true nature of their trouble.

The Biological Test for Human Blood.—Francis Williams believes that, so far as his experiments may be permitted to indicate anything, the following conclusions would express what might be inferred: (1) Ascitic fluid subjected to 65° has its power to excite antibodies considerably lessened. This may be in line with the observations of Bordet, that serum heated to 55° lost its hæmolytic power though it retained its agglutinating power. (2) The peritoneum of animals injected was quite resistant to the bacteria abundantly present in the peritoneal fluid used; it was simply drawn into sterile bottles and kept cool in the case of one of the pigs, and the fractional sterilization resorted to for one of the rabbits and another pig, failed to kill the bacteria. Yet the animals thrived during the injections in all instances of the second group.—*Pacific Medical Journal.*

The Treatment of Cancer by Its Own Toxins.—P. J. McCourt gives his experience with this plan of treatment and details three cases. As to results he states that, excluding those cases of which an adequate history could not be secured as well as others whose professional supervision was palpably defective, the conservative results obtained by this method may be summarized thus: In 5 per cent.—the advanced and extremely malignant—the toxins were found to be entirely valueless. In 90 per cent., relief from pain, fetor, hemorrhage, insomnia, vesical and rectal tenesmus, etc., has been marked and life materially prolonged. And in 14 per cent., indurated glands have become normal, ulcers have healed, body-weight has increased, a complete cessation of all objective and subjective symptoms has ensued, and the patients are, apparently, restored to their former condition of health. Whether this relief is permanent can be answered only by time.—*Medical Review of Reviews.*

Canine Malaria.—A. B. Dalgetty is of the opinion that we must study more closely the diseases of animals if we are to understand properly those of man. He gives an account of a blood parasite, apparently malarial, which he has met with in a dog—a white fox terrier. When the pup was a little over seven months old he began to seem out of sorts—he improved, but again afterward showed signs of illness. A little later, one day after his bath, he fell down in a faint and passed involuntarily a quantity of blood-red urine. These attacks continued for the next three days, after which he recovered to some extent but the anæmia was very marked. The examination of the blood during an attack proved that the disease was of a malarial nature. The oil immersion-lens showed a considerable number of free, actively moving round or oval spore-like bodies making their way among the blood corpuscles. A stained specimen showed their diameter to be a quarter to one-third that of a red cell. Their outline was distinct and was separated from the central part by a clearer, less stained zone, while the center was distinctly more deeply stained than the rest of the body. Nearly all of these parasites were extra-corpuscular, though there were one or two intra-corpuscular specimens. The infected corpuscles were paler than the others, but not increased in size. The parasite looked larger outside than inside the blood cell. One blood count gave two million eight hundred thousand per c.mm., and another three million per c.mm. Judging from the paleness of the blood-drop, the hæmoglobin was very low. An examination of the blood-colored urine showed no red corpuscles, hence the color must have been due to the presence of hæmoglobin alone. The spleen could not be felt. The heart sounds were irregular. The administration of quinine was followed by immediate improvement. Since the disease was doubtless due to a malarial parasite, it is an important question to consider whether the dog might not be one source of infection to man. The presence of hæmoglobinuria in this case is also worth remembering in connection with the causation of blackwater fever in man.—*The Journal of Tropical Medicine.*

MEDICAL RECORD:

New York, June 18, 1904.

THE TRANSMISSIBILITY OF MALIGNANT NEW GROWTHS FROM ONE ANIMAL TO ANOTHER.

THIS is a most important phase of cancer research. All experiments undertaken on these lines have been entirely negative. Owing to the close similarity of the histological characters of malignant new growths in man to those of the normal tissues, it has been thought that normal tissues when transferred to new sites would continue to grow and ultimately might form tumors. Transplantation of testis and ovary in mammals has been frequently performed, but no other results have been obtained. The working members of the British Cancer Research Fund during the past year have been making control investigations as to the possibility of transplanting chorion but with negative results.

In short, transmission of cancer from man to animals, or *vice versa*, has never been successfully performed, although several experiments have been made in this direction, notably by Shattock and Ballance, but with complete failure. The report of the British Cancer Research Fund says that, in the light of our present knowledge of cytolysines and cytoxines, it can be understood how such attempts were doomed to failure. The consequences to the transferred tissue are exactly analogous to the fate which befalls the blood-corpuscles of one animal when injected into another of a different species. The transferred cells are treated as albumins strange to the species. The occasional successful transmission of malignant new growths from one animal to another of the same species, has been effected. Jensen of Copenhagen and Borel of Paris have made the most recent observations of this kind. Jensen transplanted an epithelioma occurring sporadically in a white mouse into other mice; and Borel successfully transplanted an adenocarcinoma under similar circumstances. Jensen in his experiments recorded 30 to 60 per cent. of successes, while Borel obtained only 10 per cent. of successes with the adenocarcinoma which he used. These two observers, however, differ in the interpretation of their results, Jensen holding that the tumors develop from the actual cells introduced; Borel, on the other hand, conceiving the phenomena to require the intervention of a "virus cancéreuse" for their explanation.

Dr. Bashford and Mr. Murray have been investigating, at the Central Laboratory, with a portion of one of Professor Jensen's experimental tumors which he placed at their disposal. A careful and continuous study of the site of transplantation in nearly three hundred mice has been made at intervals. For the earlier stages, mice were killed hourly up to forty-eight hours after inoculation. The total number of transplantations on which the observations have been made exceeds 1800. The general result has been a complete confirmation of Jensen's conclusions. The new tumors which develop are the genealogical descendants of the cells introduced.

Transplantation is artificial metastasis, and only differs from natural metastasis in that the latter occurs spontaneously in the individual primarily attacked, whereas the former is experimentally effected from one individual to another. The process is in no sense an infection, the tissues of the new host not participating in the formation of the new parenchyma.

The investigators are firmly of the opinion that the problem of the genesis of a malignant new growth must be distinguished from that of the circumstances which permit of its continued existence. The report further states that the suitability of the animal into which the inoculation is made seems to be of importance; but greater weight attaches to the character of the tissue introduced when the inoculations are made into animals of the same race. Age seems to have no influence on the proportion of successful transplantations, in contrast to its cardinal importance in determining the initiation of the cancer cycle. Pregnancy and full sexual activity in the male constitute no bar to successful transplantation. In the light of the phenomena of immunity, it is interesting to note that it is possible to obtain multiple tumors from transplantations performed on the same date, and that transplantations can be successfully performed in animals in which tumors have already developed fourteen days to ten weeks after the first effective transplantation. In all successful transplantations the parenchyma of the tumor preserves the same character. The rate of growth and relative proportion of stroma is subject to variation.

The deductions drawn from the investigations of the British Cancer Research Fund with regard to the transmissibility of malignant new growths from one animal to another are stated in the report in the following words: "A general review of the facts relating to the fate of normal tissues when transplanted to fresh sites, contrasted with the occasional maintenance of vitality and power of proliferation of cancerous tissue under similar circumstances, points indubitably to the same conclusions as have been drawn from the study of the zoological distribution and comparative nature of cancer. The latter line of inquiry led to the conclusion that the elucidation of the problems of cancer was to be sought in the potentialities of the cell itself; and the nature of the transmissibility of cancer reduces the field of inquiry to the cell again, and leads one to seek for the peculiarities in the cell-life of normal and cancer tissues which limit the power of independent existence in the former, and raise this power to the level of being the chief characteristic of the cells of the latter."

Although no striking results have been obtained in cancer research during the past year, some progress has been made in this line of study. The most satisfactory feature of cancer research is the interest of the public in the matter, and the fact that in-

vestigators in every civilized country of the world are energetically engaged in endeavoring to learn all that is to be learned about the disease.

CURE OF REDUCIBLE HERNIAS BY ALCOHOL INJECTIONS.

In No. 369 of the *Sammlung klinischer Vorträge*, Dr. E. Steffen gives the results of the treatment by him, between 1886 and 1898, of 1182 cases of reducible hernia, by Schwalbe's method of injecting alcohol into the tissues around the sac. Schwalbe's original procedure (as outlined by him in 1876 in the *Deutsche medizinische Wochenschrift*) consisted in the injection into the tissues around the neck of the sac (not into the sac itself), of from two to three grams of 20 to 70 per cent. alcohol; the underlying principle being that a connective tissue hyperplasia should follow such an irritation, especially as alcohol is believed to be prolific of just such hyperplasias, such scleroses, in the organs. The injections were made daily for four to fourteen days, according to the sensitiveness of the patient and the degree of the subsequent reaction. With umbilical hernias, adhesive plaster strips were simultaneously used; with others, the truss. An intermission of a week or two following, after which the treatment is resumed. The result is a diffuse hardening around the neck of the sac, which shrinks and finally closes completely.

Since Schwalbe's original publication, his method has been used by a number of physicians and surgeons. Thus, in 1891, Steffen himself published the results obtained in 293 cases, a cure being affected in 80 per cent. of the small and medium sized reducible hernias. The longest duration of treatment was four years, the shortest one year.

Steffen's modification of the Schwalbe treatment consists in the substitution for the alcohol, of a mixture consisting of 100 grams of 50 per cent. alcohol with ten drops each of dilute phosphoric acid and formalin. In a case now and then, in which this mixture fails to bring about the necessary local reaction, he substitutes an injection of one or two grams of extract of oak bark, which always occasions a very strong reaction. Solutions of tannin are not to be substituted for the bark, as they are too apt to induce abscess and necrosis.

The present series of cases extends from December, 1886, to the spring of 1902. During this period Steffen has treated 1,052 patients with 1,372 hernias, but on account of various reasons (non-completion of treatment for various causes, indifference, intercurrent diseases, etc.), only 901 patients and 1,182 hernias are brought into the analysis. Of the hernias, the inguinal were 88.15 per cent; crural, 7.02; umbilical, 3.90; and hernia of linea alba, 0.93. As regards outcome, the initial results were: cured 75.3 per cent; improved, 7.1; and not cured, 17.6. By "cured" is meant a hernia which upon coughing and pressure, in both the sitting and recumbent posture, the earlier perceptible hernia is no longer visible or palpable; and, in the case of an inguinal hernia, in which the finger invaginated in the scrotal tissue cannot detect any impulse. As a result of treatment, the region of the injected area is harder than normal, and sometimes strand-like. The invaginated finger no longer enters an orifice but abuts against a thick-walled cushion. In not a few cases, however, the finger still penetrates a very narrow canal, though the case must be regarded as cured. That a complete closure is not absolutely necessary to a cure, results from the normal condition; and from the fact that there are many persons with wide hernial apertures or canals, in whom, nevertheless, no hernia protrudes, probably an account of a peritoneal adhesion at the inner ring.

Of the cures, 178 have persisted from 11 to 16 years; 305 between 6 and 10 years; and 221 from 1 to 5 years. In 77 cases the cure persisted till death or disappearance from under observation. Of the 17.6 per cent. improved, about one-half offered no evident cause for the failure, but in the other half Steffen believes the inefficacy of treatment to have been due to the existence of chronic bronchitis and emphysema (19 cases); cough of influenza (4); emaciation with flabby musculature (6); and obesity (5).

Of the cured, 111 (or 12.5 per cent.) relapsed, the causes of relapse being the same conditions, and indeed in just about the same proportions, as those which involved non-healing. About one-third of the relapses presented no obvious cause. Relapsed cases can be treated again in the same way.

The author concludes that the treatment of reducible hernias by Schwalbe's method, as modified by himself, yields about 75 per cent. of initial cures, so that the patient can do all sorts of work without a truss and upon examination no hernia can be proved to exist. The duration of the treatment is at least one year in the case of small and recent hernias. The larger the hernia—that is, the wider the orifice and the older the hernia—the longer the time necessary for a cure (two or three years or more). In most cases the patient can go about as usual, and the treatment is to be carried out with constantly lengthening intervals. Special precautions are not necessary. Very wide apertures demand at the beginning daily injections of small doses with rest in bed. In general the method is applicable to all reducible hernias which can be retained by a truss. Hernias partially retainable can, as a rule, be improved, so that by aid of a truss the patient can carry on work again efficiently. The method is suitable for all ages. As it involves no narcosis and no long confinement, it is in many cases in the aged to be preferred to the radical operation. A treatment cumulative and compressed into a short time is not to be recommended, as the initial acute inflammation induced must be transformed into a chronic stage, and for this a longer time is needed. A toxic subsidiary action (*e. g.*, urticaria) is rarely observed. With the proper care and reference to the anatomical conditions, unfortunate accidents are extremely rare. The procedure cannot, however, be said to be absolutely without danger. The mortality is about 0.04 per cent., as against 0.34 per cent. with operative treatment.

For initial results, the injection method evidently cannot compare with the radical operation, as the latter yield nearly 100 per cent. of initial successes. As regard relapses, however, while it is not yet possible to state accurately the results of the operative treatment, Steffen's own observations would lead him to think the number not greatly below the 12.5 per cent. which occurs with the injection treat-

ment. Kocher, to be sure, had only 1.2 per cent. of relapses, but other operators have had as high as 10.8, 11.9, and 15 per cent.

The injection treatment will be properly characterized if we say that it is a perfectly practicable restoration procedure in the treatment of reducible hernias which is suitable for a great number of cases, and is welcomed by many patients.

And as the treatment is one within the reach of every physician, and does not demand the developed surgical technique, but can be easily carried out, it deserves far more consideration than it has heretofore received. The author does not, however, say that he prefers it to the radical operation, but remarks that there are many patients who will not submit to that procedure, and for them the injection treatment can be used with good success.

LÆVULOSURIA AS AN INDEX OF HEPATIC DISEASE.

WRITING in the *Deutsche medicin sche Wochenschrift* for May 5 last, Dr. B. Chajes reviews our present knowledge upon this subject, adding the results of his own observations. In 1901, H. Strauss, on the basis of a study of twenty-nine cases of hepatic disease, and of fifty-eight cases of non-hepatic conditions, expressed the opinion that in the presence or absence of lævulosuria we have a better and more definite test of liver function than we have hitherto possessed. (Previously Sachs, one of Strauss's assistants, has shown that frogs with the liver removed showed less tolerance for lævulose than did the normal animals, the tolerance for grape sugar and galactose remaining unaffected.) Of Strauss's twenty-nine cases of hepatic disease, about 91 per cent. showed lævulose in the urine following the administration of it by the mouth. On the other hand, of the non-hepatic cases, only 10 per cent. showed this symptom under like conditions. Since Strauss's publication, his results have been abundantly confirmed by a number of observers, and with one or two exceptions confirmed quantitatively, most observers having found the symptom in about 90 per cent. of their hepatic cases. Taking all the recorded and concordant cases to date, lævulosuria has been found in forty-seven out of fifty-five cases of hepatic disease, or in about 85 per cent. Only one recent worker, Landsberg, is, as regards frequency, in opposition to the general consensus, he finding the symptom in only 43 per cent. of twenty-one hepatic cases investigated by him. In one of his negative cases, however, vomiting supervened shortly after the administration of the lævulose.

The procedure adopted by Chajes was to administer 100 grams. of lævulose in 500 cubic centimeters of water on a fasting stomach, and to test the urine passed during the next four hours by the usual Trommer's test, by fermentation, by polarization, and for the Selivanoff reaction. The result was regarded as positive if, besides rotation to the left, unequivocal fermentation occurred together with reduction and a Selivanoff reaction were obtained. In case of divergent results, special weight was laid upon the simultaneous occurrence of rotation to the left with fermentation, it being known that reduction and a positive Selivanoff reaction are not unequivocal, other substances than lævulose yielding them.

Tested in this way, in twenty-one cases of non-hepatic conditions (neurasthenia, arthritis, bronchitis, neuritis, pneumonia, etc) lævulosuria was present in only one (4.8 per cent.), with a doubtful reaction in the second. While Chajes's paper was passing through the press, Samberger has found the test positive in every one of eleven cases of hepatic disease. So that the final statistics to date stand: In 105 cases of hepatic disease, lævulosuria has been found in about 88½ per cent.; while in non-hepatic conditions it has been found in but fifteen out of ninty-nine cases, or about 15 per cent. The present state of the evidence would then seem to warrant the view expressed by Baylac and Arnaud, who regard the presence of lævulosuria as indicative of organic or grave functional disease of the liver.

THE AMERICAN WOMAN.

The native-born American woman has been made the subject of discussion almost *ad nauseam*, indeed it would be a matter for no surprise if she were to regard herself as a being apart. Her energy, her brightness, and resourcefulness has been lauded to such an extent that it might well be believed that the women of other countries cannot be considered in the same category with her. This, too, is true so far as it goes, and in many qualities the American woman stands supreme. Unfortunately, however, she fails in the most important one of all, that of maternity, and fails in consequence of her cultivation to excess of those attributes which are generally thought not to be within a woman's province. Her physical powers suffer in proportion as her mental powers increase, and as a propagator of the race she cannot compete with women of stronger bodies but of less highly-trained brains.

Dr. Emil Reich, a German, who lived for five years in this country, has recently written on this matter in a British periodical. He draws attention to the fact that one outcome of the overmentalization of the American woman, and the hypergalvanization of her energy, is the breakdown of American maternity, which he regards as one of the most serious phenomena which cloud the future of the United States. The writer points out that America relies for the increase of its population on a continuous inflow of alien immigration, without which the population would have become already stationary, and would, in the future, assuredly decline. He goes on to show that in the past many a prosperous nation has been brought to ruin by its women—Rome, for instance—and likewise recalls that the Spartan married woman, a typical example of defeminization in the worst sense, contributed at least as much, or more, to the downfall of her country as the hetæræ to the collapse of Athens. Although there is little fear that American women will ruin their country, the relative unproductiveness of the native-born American woman is much to be deplored.

MINERS' PHTHISIS.

A valuable object lesson on the danger to life and health incurred by those who work in a dust-laden atmosphere, is now being afforded by the prevalence of the disease known as miners' phthisis in the Transvaal gold mines. The subject of miners' phthisis was brought up by Dr. Thomas Oliver of Newcastle-on-Tyne at the meeting of the British Medical Association last summer, and was considered in the MEDICAL RECORD.

The malady has reached so grave a stage among the gold mines of South Africa that questions have

been asked in the House of Commons, and a member of that legislative body has—as usual with his countrymen—written to the lay journals in order to arouse public interest in the matter. Mr. Haldane quoted figures presented last summer to the House of Commons concerning the mortality from miners' phthisis. The death rate of the white rock-drill miners of the average age of thirty-five years was then over 70 per 1,000. The mortality among English coal miners is 6.3 per 1,000, of ironstone miners 6 per 1,000, and of tin miners 8.1 per 1,000. This very considerable difference in mortality rates leads to the obvious inference that insufficient precautions are taken in the Transvaal mines to prevent the scattering of dust with its serious consequences. According to the *Lancet of* May 14, the Transvaal Medical Society has recommended that "dry mining should, as far as possible, be converted into wet mining," and the commissioners appointed to investigate the matter have suggested that jets and sprays of water would, in combination with good ventilation, prove an effective preventive against dust.

Dr. Oliver summarized his views with regard to miners' phthisis as follows: (1) miners' phthisis is not caused by the inhalation of any of the gases present in the mine. (2) In pneumokoniosis there may be not only excess of fibrous tissue, but even cavities and tubercle. (3) The disease is, however, non-tuberculous. (4) Accepting this view of the pathology of the disease, there is hope that by improving ventilation and by allaying the dust with water, miners' phthisis may be prevented.

The fact that dust is a factor of much importance in the causation of disease of the respiratory tract has been brought into prominence in New York city of late. Street-cleaners have been found to be attacked by pulmonary tuberculosis out of all proportion to their numbers. The prevalence of phthisis among these men is, as with miners, undoubtedly largely due to the dust with which they are constantly coming in contact. New York is probably, owing to a variety of causes, one of the dustiest cities of the world. Buildings are being demolished in all parts of the city without cessation, and sufficient care is not taken to prevent the dust caused thereby from being conveyed by the breezes hither and hither. If the city ordinance prescribing that water should be used for the purpose of preventing the dust from being wafted through the air to the discomfort of all, and to the physical detriment of street-cleaners in particular, were strictly enforced, New York would be a much pleasanter city in which to live, and those whose duty it is to keep the streets in good order would not fall victims to consumption so readily as they are stated to fall at present.

The Odor of Race.

Western nations, with their usual conceit, imagine that they are superior in every respect to the races of another color, and consequently to those of the far East. One of the charges which white men bring against the negro is that the odor emanating from him is the reverse of pleasant, and occasionally, in hot weather, is almost unbearable.

The Caucasian never pauses to think that possibly the odor of his skin is by no means pleasing to the sense of smell of the negro or the Indian. Nevertheless, it is stated that the smell of the white man is not so fragrant to the negro as is imagined, but is, in fact, objectionable to a degree.

According to a recent issue of the *New York Times*, a Japanese medical man has published a treatise concerning the odor of the Occidental races, declaring that it takes some time for the Oriental to become accustomed to it. The writer advances the theory—which has been discussed before—that each race has its peculiar odor, that it is partly radical, but is in a measure influenced by dietary and other conditions.

The Japanese do not smell each other, but the perfume from their bodies is wafted by the breezes to the Russians who can distinguish the smell of their enemies at a long distance. The writer, however, states that it is nothing like the pungent and penetrating emanation proceeding from the Western nations, in which traces of garlic and ancient cheese and the volatilization of a coarse and overabundant dietary are so sure to be found.

There are reasons to think that the Japanese doctor may be right, and perhaps each race has its characteristic odor. Certain it is, that primitive nations have a much keener sense of smell than the members of a highly civilized race. With civilization and the habit of living in an artificial manner, from disuse the senses of sight and smell become less acute. The Japanese have not embraced civilization for so long a period as to lose the qualities of a people living in a state of nature. Indeed, the great majority are not civilized at all. Again the mode of living of a large proportion of Europeans, eating meat to excess, drinking beer and spirits to excess, and feeding grossly in all respects lends plausibility to the theory that to clean feeders and temperate people, as the inhabitants of the far East are, the odor of the dwellers in Europe is to their sensitive perceptions both distinct and unpleasant. The whole subject is interesting and worthy of further investigation.

The Decrease of Consumption in New England.

Dr. S. W. Abbott, secretary of the Massachusetts State Board of Health, has issued a paper on this subject. The writer by the term "consumption" refers solely to pulmonary tuberculosis, a disease which accounts for at least 75 per cent. of all the deaths from tuberculosis in the New England States at the present time. The points considered by Dr. Abbott are: (1) The prevalence of consumption at the present time. (2) Its decrease in the last years of the nineteenth century. (3) The comparative mortality of the sexes from consumption and the relative decrease in each sex. (4) The comparative mortality from consumption at the different ages of life and the relative decrease at each age.

The question is dealt with at some length, but among other interesting points brought out by the author is a comparison between the state of affairs regarding consumption in England and Massachusetts. The differences are: (1) A generally lower rate for England through the entire period. (2) The difference between the death rates of males and females is generally less in England than it is in Massachusetts. (3) The death rate of females also descends more rapidly than that of males in England, and becomes less than that of males at a period (in 1866) nearly twenty years earlier than the date when the same change takes place in Massachusetts. The conclusions arrived at by Dr. Abbott are the following: (1) The death rate from consumption in New England at the present time is somewhat less than 20 per 10,000 living inhabitants. (2) The death rate from this cause has diminished largely in all the New England States—in some, with fairly accurate registration, as much as 50 per cent. in the half century; and this decrease appears to be going on now more rapidly than in earlier years. (3) The death rate of women from consumption has decreased more rapidly than that of men; while in

earlier years it was greater. (4) This death rate from consumption at every age of life has also decreased, but more at older than at younger ages.

The experience of the New England States regarding the decrease of consumption is that of all countries in which rational measures of prevention are in vogue. The optimistic view of Dr. Hillier that a pursuance of the methods now practised in England and Germany will render the disease extinct within a generation in those countries, is not shared by the majority of the medical profession. There will be sufficient reason for pride if a continued steady decrease in its prevalence is exhibited. The conditions of life cannot be so altered in so comparatively short a period as a generation as to justify the prediction that consumption will be unknown fifty years from now.

News of the Week.

The Rush Monument.—The bronze statue of Dr. Benjamin Rush, presented to the United States Government by the American Medical Association, was formally unveiled last Saturday, June 11, on the grounds of the Naval Medical Museum and accepted by President Roosevelt. Many members of the association, members of the Cabinet, and other officials were present. Dr. J. C. Wilson of Philadelphia, on behalf of the association, delivered a tribute to Dr. Rush. In his speech of acceptance President Roosevelt said that he accepted on behalf of the nation, "the gift so befittingly bestowed by one of the great professions—this statue of a man who was eminent not only in that profession, but eminent in his service to the nation as a whole." He would improve the occasion, he said, to deliver a short sermon to the eminent specialists before him on the duty of citizenship. "To-day," he continued, "no specialist in a democratic country like ours can afford to be so exclusively a specialist as to forget that one part of his duty is his duty to the general public and to the State. Where government is the duty of all, it of course means that it is the duty of each, and the minute that the average man gets to thinking that government is the duty of somebody else, that minute the republic will begin to go down. It is a fortunate thing for our country that we should have before us the lives of men like Rush, who could take a part in our public life as distinguished as is implied by his having been a signer of the Declaration of Independence, and yet to do it without a particle of neglect of the man's own proper duties."

Medical Practice Law in the Indian Territory.—Shortly before adjournment Congress passed a law regulating the practice of medicine in the Indian Territory. No one is allowed to practise without being registered in the office of the clerk of the United States court in the district. One desiring to practise must present his or her diploma to the Board of Examiners (appointed by the judges in the several districts) for the district. If the diploma is approved by the board, registry may be obtained without examination. No diploma issued after July 1, 1904, will be accepted unless it has been granted by a college requiring a preliminary examination and a four-year course of medical study. In the absence of a diploma or the possession of one not approved by the board, an examination will be required.

The German Medical and Surgical Exhibit at the World's Fair is replete with interest. The exhibit is in the Palace of Education, occupying six rooms, and contains a display of the results of the latest medical research and experiment. The various ways in which epidemics and infectious diseases are fought by inoculation are shown by guinea-pigs which have been inoculated and killed at certain stages. In the other rooms are wax casts of difficult operations showing the various steps of the operations, wax casts of rare diseases and the method of handling them, and photographs and specimens. Dr. Kaiserling installed the exhibit.

Chicago's Low Death Rate Explained.—The low death rate of Chicago will be shown in all its bearings at St. Louis, at the Exposition. Health Commissioner Reynolds will personally install the exhibit, which consists of a series of thirty charts, showing facts by comparative lines, four volumes giving blanks used by the department, photographs of the public baths and bathing beaches, and of the isolation hospital, and views showing the laboratory outfits for diagnosing diphtheria, pneumonia, and other diseases. The chief gain has been in children under five years of age. This is associated closely with the department's inspection of milk. The chart diagrams show that the following diseases are diminishing in Chicago: Asiatic cholera, consumption, croup, diphtheria, diarrhœal, malarial, nervous and puerperal diseases, measels, scarlet fever, typhoid fever, and whooping-cough. The following are on the increase: Bronchitis, cancer, heart disease, influenza, nephritis, and pneumonia. In 1893 46 per cent. of all deaths were of children under five years of age, while in 1903 the percentage was only 28. The average duration of life in Chicago has lengthened from fourteen years in 1869 to thirty-two years in 1903. While one person died of heart disease in 1854 out of ten thousand, 11 died in 1903. No deaths from nephritis occurred fifty years ago, but in 1903 there were 9 deaths in every 10,000 of population. Cancer deaths have increased from one to 5½ in 10,000 persons, while pneumonia, the most fatal scourge of Chicago, has increased its victims from 5 in 10,000 in 1854 to 25 in 1903. Tuberculosis, however, has fallen in the same time from 33 to 15.

University of Pennsylvania Medical Laboratories.—The new laboratories of pathology, physiology, and pharmacology were opened on June 10 with elaborate ceremonies. The presentation address was made by Mr. J. Vaughn Merrick on behalf of the Committee on Medical and Allied Schools, and the address of acceptance by the Provost, Mr. Chas. C. Harrison. Additional addresses were made by Dr. H. P. Bowditch on behalf of Harvard University, by Dr. Russell H. Chittenden on behalf of Yale University, by Dr. George Dock on behalf of the University of Michigan, and by Dr. Horatio C. Wood, Professor of Therapeutics, Materia Medica, and Pharmacy in the University. The new building is two stories high, with a frontage of 340 feet and a depth of 200 feet. It is quadrangular in shape and cost $700,000. It faces the north and contains many small rooms for research, rooms for professors and assistants, a library, etc. The first floor will be devoted to physiology and pharmacology, the second exclusively to pathology.

New Laboratory Building of the New York University.—The council of the New York University, on the recommendation of the faculty of medicine, has arranged for the immediate erection of a six-story edifice adjoining, and harmonizing in its architecture with the main college building. This will be completed and ready for occupancy with the opening of the college session of 1904-'05. The first floor of the new building and part of the second will serve to increase the number of teaching rooms in the college clinic. The remainder of the second floor will be used for the examination of speci-

mens sent from the college clinic and from the medical and surgical services of the college in Bellevue Hospital. The third, fourth, and fifth floors will be occupied by large class-room laboratories, devoted respectively to normal and pathological histology, bacteriology, and applied pathology and chemistry. The sixth floor will accommodate the increasing work in anatomy, experimental surgery, and operative surgery on the cadaver. The removal of the class-room laboratories above-mentioned from the main college building will allow of immediate additions to the physiological and pharmacological laboratories and the pathological museum, and furnish greater facilities for research workers.

The Medical Department of Washington University, St. Louis, will have an interesting exhibit in the Educational Building at the World's Fair, intended to illustrate some methods of teaching and the results of original work done in the University. A bone modeling laboratory is part of the curriculum, and clay models of bones made by the students in the study of osteology will be exhibited. There will also be models of the temporal bone, showing the relations of the parts within the temporal bone to the surface. In addition to these there will be illustrations, with dried skulls and photographs, of the methods of operating for the relief of deformities due to mal-relationship of the dental arches. detailing the methods of making the sections in different parts of the lower jaw as required to overcome the different pathological conditions, and the results of these operations.

The Fourth Pan-American Medical Congress will meet in Panama the latter part of December. The Pan-American Congress meets every three years. It was started by Dr. William Pepper of Philadelphia, Dr. C. A. L. Reed of Cincinnati, Dr. Albert Vander Veer of Albany, and Dr. H. L. E. Johnson of Washington. The first meeting was held in Washington in September, 1893, the second in Mexico in 1896. The third was to have been held in Venezuela in 1899, but was given up on account of the war in that country. The place of meeting was changed to Cuba, but had to be postponed until 1901 on account of the fever there. These meetings have always been well attended, and it is thought that Panama will be an interesting place for the convention.

Pure Milk for the Poor.—The citizens of St. Louis have established a laboratory for the distribution of pure milk to the poor during the summer. Those among the poor who are able to pay for the milk will be supplied at a slight advance over the cost, but it will be supplied free to those who cannot pay for it. The reports of the reduction in the mortality rate among infants during the summer months in other cities have encouraged the citizens to operate such a laboratory in St. Louis. Dr. Albert Merrell, Member of the Board of Health, and Dr. H. J. Scherck, Chief Dispensary Physician, are in charge of the work.

New Fordham Hospital.—The trustees of Bellevue and Allied Hospitals have purchased from the Jesuit Fathers at St. John's College at Fordham, N. Y., a plot of ground equivalent to four city lots for $80,000, on which will be erected a public hospital. The erection of the hospital will be begun at once.

"Liquid Sunshine" at Hot Springs.—As a result of certain experiments recently made at Hot Springs, Ark., it is asserted that the waters there contain radium or some radioactive substance. In consequence of these claims, the United States Government has engaged Profs. Bertram B. Boltwood and J. Joseph Hyde Pratt of New Haven, Conn., to make a thorough investigation of the waters to determine upon what this radioactivity depends.

Dr. Samuel B. Ward has been elected dean of the faculty of the Albany Medical College to fill the vacancy occasioned by the resignation of Dr. Albert Vander Veer. The latter's resignation was necessitated by a new law which compelled him to give up his office as dean or else that as a regent of the University of the State of New York.

An Investigation of Nostrums.—The Post Office Department is causing an analysis of some of the widely advertised patent medicines to be made, and when it is discovered that the medicines are rank frauds the advertising matter will no longer be allowed the use of the United States mails. The move is the outgrowth of a series of investigations which have been made by the Bureau of Chemistry of the Department of Agriculture.

American Association of Genito-urinary Surgeons.—This society was to have held its annual meeting in St. Louis, beginning on Monday of this week, but the attendance was so poor at the opening session that the meeting was adjourned until next year.

Canadian Medical Association.—The thirty-seventh annual meeting of this association will be held in Vancouver on August 23, 24, 25, and 26. This is the first occasion on which the association has met west of Winnipeg. The principal guest will be Mr. Mayo Robson. A banquet will be held in Vancouver on the evening of the second day. The next day the delegates and their friends will make an excursion to Victoria. A run will be made to William Head quarantine station. and the return to Victoria will be made by way of Esquimault, to view the naval arrangements and the fortifications. Upon arrival at Vancouver, a reception will be arranged for at the legislative buildings. The following day will be given up to visiting the many points of interest about the city, including the sea drives, and in the afternoon Esquimault and the Naval Hospital will be visited. A trip up the Arm by moonlight is also contemplated on the second day and a band concert will be given on that evening.

Dr. Winfield Scott Hall of Berwyn, Ill., has been elected president of the American Academy of Medicine, being the second Western man to receive this honor in twenty years. Dr. Hall has been professor of physiology in Northwestern University Medical School since 1895. He is a member of the Chicago Academy of Sciences, and of other scientific and medical organizations.

Offer to Unite with State University.—Harvey Medical College has made a proposition to the University that it be absorbed by the State institution, as was the College of Pharmacy a few years ago, free of indebtedness. Dr. Frances Dickinson, President of Harvey College, says the proposition was made to the Committee on Pharmacy, which was in session here about two months ago, and it is now being considered by the Medical Committee of the University. Harvey Medical College has been in existence for ten years, and has graduated twelve hundred students during that time.

Dr. Henry W. Bettmann has been elected president of the Board of Trustees of the Public Library, Cincinnati, for the coming year.

The Ex-Internes Association of the Cincinnati Hospital held a banquet June 4, at the Queen City Club. Dr. J. H. Landis acted as toast master. Responses were made by Drs. W. E. Kiely, J. E. Greiwe, T. W. Hays, and Percy Shields. There was also a number of impromptu speeches, songs,

and recitations. Drs. Louis Heyn, C. W. Smith, Oscar Burghausen, and Casper Hegner sang in concert a composition entitled "Old Hospital," to the tune of "Old Heidelberg."

Illinois Camp for the Tuberculous.—A camp to accommodate thirty poor tuberculous patients was recently opened near Ottawa, Ill., under the auspices of the Illinois State Medical Society. Dr. James W. Pettit of Ottawa is to be in charge, and it is expected that the camp will be virtually self-supporting.

Dr. Lillian Wyckoff Johnson, assistant to President Charles W. Dabney, recently of the University of Tennessee, was recently inaugurated president of the Western College for Women. She succeeds President Leila S. McKee, who has held the office for sixteen years and has recently resigned to be married.

Officers of the American Dermatological Association.—At the twenty-eighth annual meeting of this society, which was held at the International Hotel, Niagara Falls, on June 2 and 3, 1904, the following officers were elected for the ensuing year: *President*, Dr. William T. Corlett of Cleveland, Ohio; *Vice-President*, Dr. Frank H. Montgomery of Chicago; *Secretary and Treasurer*, Dr. Charles J. White of Boston; *Member of Council*, Dr. John A. Fordyce of New York. It was decided to hold the next meeting of the association in New York City, on December 28, 29, and 30, 1905.

Hospital Bequests.—The late James Lowman of Cincinnati left an estate valued at $1,000,000. He bequeathed $1,000 to the Jewish Hospital, $1,000 to the Jewish Home for Aged and Infirm, $1,000 to the Jewish Orphan Asylum, and $200 to the Associated Charities.

The Covington (Ky.) Board of Health was reorganized last week. Mayor Brach called the meeting to order. Dr. M. Behrman was elected secretary. The business of the meeting was to elect a new health officer to succeed Dr. C. W. White. Dr. H. F. Wilson was elected to the position.

Obituary Notes.—Dr. JAMES W. KEISER died at Reading, Pa., on June 6, from typhoid fever, at the age of forty-three years. He was graduated from the Medical Department of the University of Pennsylvania in the class of 1882.

Dr. PHILIP W. BEALE died at Camden, N. J., on June 7, as a result of cerebral hemorrhage, at the age of forty-seven years. He was graduated from Jefferson Medical College in the class of 1876, and he has been coroner of Camden County since 1894. He served as a member of City Council in 1895, and he was for ten years a pension-examiner by appointment of President Harrison.

Changes in the Pulse Due to Stimulation of Special Senses.—The effect on the pulse of stimulating the senses of hearing, taste, and smell has been carefully studied by M. Heitler. The sphygmograph showed a distinct acceleration in the pulse rate of ward patients when a noisy street car passed the windows, and the same effect was also observed when other sounds were produced. It was found that a clanging sound was followed by a greater acceleration than that produced by other disturbances, and, moreover, that high notes had more effect than deep tones. Tests made on the sense of smell showed that vinegar and camphorated oil produced an increase, whereas turpentine, alcohol, and benzine were followed by a depression in the pulse rate. Concentrated solutions of various substances placed on the tongue disclosed that sugar and salt produced an acceleration, vinegar and quinine a depression in the pulse. These observations were made in over 200 patients.—*Zentralblatt für innere Medizin.*

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent.)

GENERAL MEDICAL COUNCIL—DISORDERS OF BLOOD AND BLOOD-FORMING ORGANS IN EARLY LIFE—HYDROPS OF JOINTS—GROWTH AND DEFORMITIES—CONGRESS OF SCIENTIFIC ASSOCIATIONS—PUBLIC HEALTH NOTES.

LONDON, May 27, 1904.

THE seventy-ninth session of the General Medical Council is now sitting. It was opened on Wednesday, when the president, Sir Wm. Turner, gave another of those addresses in which he sums up what has been done since the previous meeting and intimates what is to be undertaken at the time. Many people still think that these addresses would be better omitted, as members are aware of what has been done and are prepared to follow the program.

Mr. Henry Morris took his seat as the new representative of the College of Surgeons, and Dr. Caton as that of the University of Liverpool. The president referred to the retirement of Mr. Bryant, who, as one of the treasurers, had spared neither time nor trouble in the transaction of the council's business. He also announced that Mr. Bryant has agreed to undertake for the present year the duties of the inspector of final examinations which has become vacant through the lamented death of Sir George Duffy. It has been arranged that he shall be accompanied by a Fellow of the College of Physicians, and the reports will thus be framed by experts in the two principal branches of the profession.

The attempts made to establish reciprocity between the United Kingdom and Canada in regard to practice and registration have not yet succeeded, some difficulties existing in the formation of a single register for the whole Dominion. The statistics furnished by the Army, Navy, and Indian Medical services were received as usual.

The finances of the council remain in an unsatisfactory shape, and as an offer has been made for the premises, the matter will be considered *in camera*. It may be hoped the council may be able to retrieve the error by buying such a property and squandering money on adapting it for their purpose.

The council has to consider the effect of a judgment in the High Court in Ireland which would seem to legalize practice as dentists by a commercial company—it being held that the dentists' act, as worded, is directed against a natural person only and not against a company, the effect of this decision being that a company cannot be prosecuted under the act.

The whole time of the council yesterday was devoted to penal cases.

The Goulstonian Lectures at the Royal College of Physicians have been duly delivered this month. The lecturer on this occasion was Dr. Robert Hutchison of the London Hospital, and he took for his subject, "Some Disorders of the Blood and Blood-forming Organs in Early Life." The prominent rôle played by adenoid tissue and some probable reasons for its marked development were pointed out at an early stage, as was the probable greater liability to disease on account of this extensive development. Some of the confusion that exists in respect to affections of the lymphatic glands was attributed by Dr. Hutchison to the use of a merely clinical classification and to the inadequate study of the morbid histology after death. One must agree with him that the advance of our knowledge is retarded by a terminology which has ceased to correspond with clinical and pathological facts. If we think of such terms as "lymphadenoma," or "pseudo-leukæmia," or "malignant lymphoma" or "lymphosarcoma," we may well exclaim with him how vague is the impression conveyed! But he does not consider the time ripe for a final classification. He was content to describe some classical types and discuss their relation to each other and the possible existence of intermediate forms.

He therefore described some cases of acute tuberculous adenitis, Hodgkin's disease, and lymphosarcoma, as types of three pathological processes affecting adenoid tissue in a primary and widespread fashion. He then proceeded to inquire whether these processes are entirely distinct, or do intermediate or mixed pathological types occur? Hodgkin's disease is regarded by Dr. Hutchison as quite distinct from tuberculous adenitis, each having a separate morbid histology. Nevertheless, glands which have been primary affected by the former disease may become the seat of secondary tuberculosis, and it is, perhaps, such cases that have led to the idea that the two are identical. There is less certainty with regard to the leukæmias, and again as to lymphosarcoma.

The blood disorders of early life are distinguished by less

definition of type than those of later life. Those affecting bone marrow are rare in infancy and early childhood, while several secondary anæmias and infective leukæmic and sarcomatous processes affecting adenoid tissue are not uncommon. One type of anæmia is peculiar to infancy and epitomizes in itself all the peculiarities of the other forms seen in infancy. This age is much exposed to many influences destructive of blood or inimical to its formation, *e.g.* deficient diet, digestive disorders, infective processes, etc. Further, the extent and activity of the adenoid tissue expose it to infective and malignant processes. Hence the frequency in early life of Hodgkin's disease, lymphatic leukæmia, chloroma, and lymphosarcoma.

In the course of the three lectures Dr. Hutchison referred several times to the want of sharp differentiation between the types of anæmia in early life. This indefiniteness may, perhaps, correspond with a similar want of definition in the function of the blood-forming organs and an incomplete division of labor among them at this age. Although such differentiation may be fairly complete in healthy infancy, yet under adverse conditions a reversion to the fetal condition might occur more readily than in the adult.

In such case the mother-cells of the bone marrow (myelogonia) no longer producing merely myelocytes and those of the adenoid tissue (lymphogonia) lymphocytes, but both combine to produce the particular species of cell for which there is at the time the greatest demand in the blood stream. It is in this direction, Dr. Hutchison believes, that further study of the blood disorders of early life is likely to lead to results which will considerably modify our conceptions of the processes of blood formation in general.

Hunter's School, that of St. George's Hospital, has established a commemorative lectureship, and Professor Howard Marsh delivered the first lecture on Wednesday evening. In it he treated of intermittent hydrops of the joints and also of the influence of growth on deformities. With regard to hydrops he detailed the history of several cases and had to admit that we know nothing definite as to the pathology of the disease, while the most useful treatment seems to be quinine and arsenic. In regard to deformities in childhood the lecturer emphasized the corrective influence of growth. From a clinical point of view this was far more important than the action of growth in producing deformity. The results attributed to the use of mechanical appliances were, as a matter fact, very often due to the corrective processes of growth. Professor Marsh illustrated his lecture with a number of *x*-ray photographs, and at its close was accorded a cordial vote of thanks.

The second triennial congress of the International Association of Acad mies and Scientific Societies is being held in London this week in the rooms of the Royal Society. The formal opening of the congress took place on Wedn s-day morning, although on the evening before the foreign delegates who had arrived were entertained by the Royal Society in the old British fashion with a dinner. The president this year is Sir Michael Foster, and in his address he reviewed the work done by the association since its meeting at Paris in 1901. We also outlined the projects that have been undertaken and the present position of the movement. Lord Reay was appointed vice-president and the work of the sections arranged. In the afternoon the members visited Windsor Castle and were received by the King. In the evening Lady Avebury gave them a reception.

The registrar-general's statistics give no support to the common notion that last year's disagreeable weather must have been injurious to health. For the whole of England and Wales the rate of mortality for 1903 was only 15.4, and the neighborhood of London, so far as the death rate shows, was unequalled for healthiness. Hornsey heads the suburbs with a rate of 7.9; Beckenham comes soon after with 9, and Wimbledon with 9.4. At the other extreme the city of Dublin had a rate of 22.9, a sad contrast with London's 15.7. This rate for all London is the lowest yet recorded, the two preceding years being 17.7. The metropolitan suburbs had lower rates than most of our health resorts. The huge agglomeration of villages called London occupies various levels, ranging from 1 foot to 440 feet above the sea, the mean elevation being 59 feet. Sanitarians are inclined to attribute the improved health of London to the extensive works carried out of late years, and to which we may ascribe much. In 1854 our mortality rate was 29.4. In 1888 it fell for the first time below 20. Other circumstances have no doubt assisted sanitation, especially the greater care of infant life for infantile mortality shows the most improvement.

I hear that the Army Council has appointed a committee to consider and report on anti-typhoid inoculation.

The King will lay the foundation stone of the new St. Bartholomew's Hospital early in July.

The bill for legalizing the metric system has passed the Lords and been sent down to the Commons.

The Lunacy Bill has been described by the attorney-general as creating "almost a beneficent revolution." It provides for patients to be treated in a way to conduce to their restoration rather than to keep them in asylums.

Department-Surgeon General Sanderson, late of the Madras Army, died at his residence at Douglas on Monday, aged seventy-six years. On retiring from the army, ten years ago, he went to reside in the Isle of Man, and last November he was elected a member of the House of Keys for Douglas.

OUR BERLIN LETTER.

(From Our Special Correspondent.)

OPENING OF THE SUMMER SEMESTER—TEST OF THE FUNCTIONAL POWER OF THE HEART—A NEW STREPTOCOCCUS SERUM—RADIOTHERAPY—THE PHYSICIANS' STRIKE—A REFORMER IN TROUBLE—IMPROVEMENTS AT THE CHARITÉ—PROFESSORIAL CHANGES—THE KAISER'S HEALTH.

BERLIN, May 15, 1904.

SCIENTIFIC circles in Berlin are again pulsating with life. Those of our colleagues who were fortunate enough to be able to put away their stethoscopes and scalpels and enjoy a well-earned rest in Italy, during the raw weeks of early spring, have all returned to town. At the opening of the first session of the "Verein für innere Medizin" a great deal was heard of Naples, the Blue Grotto, and the Mediterranean; and, in fact, Leyden opened the summer session with an account of his vacation trip. The scientific interest was soon aroused, however, by a paper read by M. Katzenstein, in which he described his new method far determining the functionating power of the heart, By animal experiments he was able to show that resistances interposed in the arterial circulation brought about an increase in the cardiac action which could be measured. In cardiac insufficiency this was manifested by an increased pulse rate. If in the human subject lying flat on his back, both iliac arteries are compressed at Poupart's ligament for from two and one-half to five minutes, the pulse rate in a normally acting heart will remain the same or become diminished; but if there is insufficiency, the rate is increased. This method is of particular value in threatening insufficiency, as in severe typhoid fever, when assuming an erect posture may bring about a fatal issue. Leyden stated that he was familiar with this principle and often employed the method, but suggested that during the time of compression the patient be directed to breathe very superficially, as deep inspirations were likely to cause pressure changes in the circulation. Litten remarked that the inhibition in the pulse rate might be due to the sensory irritation caused by the procedure, and Krause believed that the results were dependent on the functionating powers of the blood-vessels; but the reader of the paper claimed that these facts did not affect the efficiency of his method.

At the same meeting, F. Meyer also reported the results of further experiments with his streptococcus serum. The general practitioner will perhaps be bewildered by being compelled to direct his attention to a new serum in addition to those of Marmorek, Behring, Aronson, and Moser. Nevertheless, every new factor in this field of therapeutic effort should be welcomed, even if it affords only a slight aid in the battle against sepsis, scarlatina, and other diseases of a similar nature. Meyer employed his serum in a large number of cases of angina, articular rheumatism, puerperal sepsis, and erysipelas. He injected one or two doses of the serum, each from 10 to 15 c.c., and succeeded in reducing the temperature in from twenty-four to forty-eight hours. In angina and articular rheumatism the serum was used only in severe cases. In scarlatina only the streptococcus infection was influenced but not the original disease. Good results were also secured in many cases of sepsis, and especially in erysipelas. The serum is not applicable to septic processes in closed cavities or organs, such as the lung.

Lassar expressed himself as desirous of seeing radium employed to a greater extent by the general practitioner. This wonderful substance, which has so quickly achieved a world-wide reputation, seems to be the subject of simultaneous discovery in many places. Elster and Geitel, two physicists of Wolfenbüttel, have found that the earth and the lower strata of the atmosphere are radioactive. When a certain kind of mud, "Fangoschlamm," was treated with hydrochloric acid and the mixture decomposed by electrolysis, radium was deposited in traces at the cathode. Radiotherapy was fully discussed by Lassar, in his interesting address before the "Medizinische Gesellschaft."

He employs radium bromide in doses of 1 gm., put up in small capsules which are applied to the diseased area daily for periods of half an hour, being held in place by adhesive plaster strips. No evil effects have been observed. Thus far he has treated only melanoma and carcinoma, but with better results than had been attained with any other radiotherapeutic method. Among other things he cured a carcinoma of the tongue, securing a localized action of the radium by attaching the tube to the end of a lead sound. Further reports on the results of *x*-ray treatments elicited a lively discussion on the mode of action of these agents. Numerous cases of carcinoma, especially of the breast, which had been given up as hopeless by such operators as Bergmann, were treated by Lassar with relief from the pain and the production of smooth scars. Even if this cure had thus far only extended over the period of half a year, the patients were at least free from pain, did not have any ulcerations, and had gained in weight. Bergmann remarked, however, that in the patients presented by Lassar, carcinomatous glands and infiltrations could still be felt, and that the rays produced an effect similar to that of the older arsenic pastes, which destroyed all tissue, whether diseased or healthy. The knife was therefore to be preferred in every case, for by the other methods the chances of life for the patient would be affected by the loss of valuable time. Moreover, in his own clinic, he had convinced himself of the uselessness of radium, and two of his assistants, Schlesinger and Borchard, had treated numerous cases of angioma and carcinoma without success. Extensive tissue destruction resulted in angioma, and after healing had taken place remnants of the growth still remained. Carcinoma, accompanied by simple ulceration which ran a chronic course, healed with a result similar to that secured by the employment of pastes, but radium cannot be applied in the case of a large carcinoma with deep involvement. In reply, Lassar contended that some of the cases which he presented were mammary carcinoma which had been considered inoperable, but which, in the space of six months had not developed any palpable recurrences. He also believed that the rays had an elective action and that only diseased tissues were exposed to the process of resorption. For this reason, radiotherapeutic measures were far superior to the arsenic pastes.

An interesting movement is now gaining ground in the social and political life of German physicians, as manifested in the outcome of the "strike" of doctors in Leipsic. As further references to this important question are likely to be made, a few explanatory remarks regarding the situation will not be amiss at this point. In accordance with the imperial statutes, every government employee with an annual income of less than 2,000 marks, must join an association (Kasse) whose membership consists of persons following a certain occupation, or those who live in a particular district, etc. These select their own officers and attending physicians who are nominally responsible to the government. As a large part of the population belongs to these associations, the German physicians, 30,000 in number, have necessarily been compelled to assume the treatment of many such cases. The insufficient remuneration—in many instances only 15 pfennige per call (3¾ cents), has animated most physicians to decline the appointments. Wherever an attempt was made, however, to better these conditions, the associations appointed certain physicians who served at the same time as lodge officers. The conditions grew gradually worse, and conferences between physicians and lodges failed utterly. The medical men finally formed a union for the preservation of their professional interests, the so-called "Leipziger Verband," under the leadership of the indomitable Dr. Hartmann. This association, by continuous agitation, has succeeded in having adopted at the last annual meeting of the "Union of German Medical Societies" a resolution whereby the members of these lodges are permitted to choose their physicians individually. This affords the patient the opportunity to consult whomever he desires, and also prevents the lodge officials displacing older and experienced men by others without cause. It still remained to put this principle into practice, and as the lodges would not entertain friendly overtures, recourse was had to a "strike." The physician's union organized branches in every German city, which dealt with the individual lodges and endeavored to dissuade other doctors from settling in this particular locality to take the place of their striking colleagues. In consequence of this agitation a more satisfactory basis of remuneration has been established and the choice of the physician is left to the patient. This much has been accomplished in Cologne and Munich, and the fight is being carried on in sixty-seven other cities. The most marked opposition was met in Leipsic, where there is one of the largest sick benefit lodges in Germany. In spite of all its endeavors, however, this organization was unable to attain its ends and report the necessary number of attending physicians to the governmental authorities, so the latter had to recognize the claims of the medical men. Difficulties are often interposed by the doctors previously engaged, men sometimes of no honor, whose contracts for five years' service cannot be dissolved by the lodges. In Berlin the relations of the physicians to the lodges are surrounded with especial difficulties, an account of which will be given at some other opportunity.

The majority of the thinking classes support the physicians in their struggle for existence. But even intelligent persons are apt to oppose medical progress, as is shown by the recent court proceedings against Dr. M. Hirschfeld. This gentleman has been trying for years to have a criminal law revoked dealing with the punishment for homosexual intercourse. Dr. Hirschfeld has sent petitions signed, among others, by 2,700 physicians, to the various legislative bodies, has edited the "Jahrbuch für sexuelle Zwischenstufen" since 1899, and has been very active in this particular field of work. For the purpose of gaining statistical evidence he devised a plan by which the intention and scope of the question was explained in a circular addressed to a large number of individuals. These were requested to forward the information as to their sexual relations on a postal card, but without appending any signature. At the solicitation of their clergyman, six students of theology who had received these communications, instituted suit for damages against Dr. Hirschfeld on the score of personal insult. Although the court recognized the scientific zeal and humanitarian motives which animated the doctor, he was convicted for having laid suspicion upon certain individuals for actions which are still subject to punishment by law.

It is a more agreeable task to direct the attention from these examples of doubtful and antiquated legal decisions to the progress of scientific research, as shown in the plans for the reconstruction of the buildings for the "Charité." Although the building of the new wards has resulted in a diminution of the total number of available beds, the average sick person will experience greater comfort than heretofore. Up to the present time the clinics for nervous diseases, children's diseases, psychiatry, and otology and laryngology, and Virchow's pathological institute, have removed to their new quarters, and more lately Franz König has become settled in the new structure of the surgical clinic. An attractive building in its outward appearance, the interior is also tasteful in its coloring and complete in every conceivable hygienic detail. Especially practical are the large convalescent halls, where the patients can enjoy an abundance of fresh air.

New blood has been infused into the ranks of the leaders of the "Charité" clinics with the opening of the present semester. Professor Fischer has taken the place of the late psychiatrist Jolly. The chair of gynecology, vacated by the voluntary retirement of Gusserow, has been filled by Bumm of Halle. Both are men in the prime of life, and the reputation they have gained by their past efforts, insures the success of these branches of medicine at the University of Berlin.

Although it seemed for a time as if the Emperor's illness would cast a shadow over the peaceful development of science in our city, the apprehensions have been dissipated. In better health than ever, and tanned by the Italian sun, the Emperor has returned to Berlin. His general animated appearance and his lively interest in every branch of human endeavor give the lie to the malicious reports, telegraphed from Naples in the early spring, of a return of his throat trouble.

OUR LETTER FROM NEW ZEALAND

(From Our Special Correspondent.)

TREATMENT OF LUPUS—TREATMENT OF LEPROSY—RETURN OF THE PLAGUE—DIMINISHING BIRTH RATE.

AUCKLAND, NEW ZEALAND, April 20, 1904.

My letter, in which I stated that a cure of lupus in four or five weeks might be effected by a drug which is in every pharmacopœia, has brought upon me a correspondence which my own serious and long-continued illness has prevented me from replying to.

The following account of a case of lupus exedens, published by R. Hall Bakewell, M.D., in *The Lancet* of October 10, 1857, contains all the information necessary for trying the effect of the biniodide (red) of mercury, the drug in question. I would recommend, as a measure of precaution, that the commencing dose should be half a grain three times a day, given after a meal, increased after four or five days to a grain three times a day. The drug should be continued in diminishing doses for three weeks after a cure is effected. So administered I have never had a failure to cure, or a relapse, or salivation or gastric irritation.

The case was that of a stout, healthy-looking lad, aged sixteen. About seven years before admission a pimple appeared on the inner side of the right nostril. Ulceration took place, which continued slowly increasing, with no improvement, and seldom stationary, up to the present time. The whole of the cartilaginous portion of the nose, and a considerable part of the upper lip, was destroyed. He was admitted under my care into the Purton (Wiltshire) Workhouse. He was placed on a good diet with a pint of beer a day. The sore was dressed with sulphate of copper lotion and arsenic given internally. Finding no benefit from this treatment, although the dressings were varied, he was given half a grain of biniodide of mercury and arsenious acid one-tenth of a grain three times a day. In a few days the amendment was evident, and from that time forward, for the space of three months, the sore continued healing until a perfectly sound and healthy cicatrix was formed. When about one-half of the ulcer had healed, he left the workhouse, and thenceforth attended as an out-patient. Cicatrization after this was not so rapid, owing, I presume, to change of diet; the quantity of biniodide, was then increased to a grain three times a day. After this the progress was most satisfactory. During the whole of the long period, or while he was taking these powerful medicines, he never felt the slightest inconvenience from them; there was neither salivation nor gastric irritation.

It is possible that the recovery in this case might have been a mere accident coincident with the treatment, but not a consequence of it. The circumstances of the case render this highly improbable. The cure was not effected merely by change of diet, for it continued, though requiring larger doses of the remedy after his discharge from the workhouse. No sign of ulceration had appeared when I last saw him, about six months after the healing of the ulcer. The doses of biniodide given were unusually large, but in this case, at least, the end justified the means.

I published another case about forty years after the first, in the *Lancet*, but not the slightest notice was taken of either case. When I saw the account of the use of the Röntgen rays for four or five months, I felt a little annoyed, and broke out in the letter aforesaid.

The cure of leprosy is the subject of several reports and correspondence which were laid before the British Imperial Parliament by command of Her late Majesty. I was sent to inquire into an alleged cure discovered by a Dr. Beauperthuy, a French physician residing in Cumana, Venezuela. In a letter I sent you last month I described the method of treatment. Mainly it consists in hygienic treatment, good food, air, etc., and then in the removal of the tubercles by the application of cashew-nut oil, which, as it were, dissolves them away. The effect produced on the face, for example, by four or five applications is simply marvellous. Unfortunately just when poor Beauperthuy's troubles seemed over, and he had been installed as physician to the Demerara Leper Asylum, he fell down in an apoplectic fit, and died in a few hours. Nothing was ever done, except by myself, and I proved in a few cases the efficacy of the treatment. I have also tried the oil of cashew-nut in other affections of the skin, such as moles. It is painless.

We have got rid of our smallpox by rigorous isolation, and now we have a return of plague in Auckland. A man died a few days ago, and true plague bacilli were obtained from a bubo, and also by culture. Another case is suspected and under observation, and there are several "contacts" who are inspected twice a day.

Of course, on theoretical grounds, this is all right enough, but there is another view of the question. To stamp out a single disease like plague costs an immense amount of money, and interferes very seriously with the personal freedom of a number of persons and with trade. It cost the State of New South Wales more than three millions sterling (say, fifteen million dollars) to treat the plague two or three years ago. The State bought up a most extensive and expensive frontage to the harbor in order to be able to deal effectually with the rats. You have already noticed Dr. Ashburton Thompson's report on the plague epidemic in your columns. That report shows that the bubonic plague is practically not communicated from one human being to another, and that it is the pneumonic form which is so dangerous. I have myself slept in the same ward with a patient suffering from bubonic plague, and not only felt no fear of it, but did not even speak to the medical officer in attendance about it. Whether he suspected it I don't know. Perhaps he adopted Brer Rabbit's policy—he laid low and said nuffin'. When we had the plague here before, I was selected to examine the contacts twice a day with the understanding that if anyof them were attacked I was to be shut up with them and attend them. None of them developed the disease, though some had handled the patient both during sickness and after death.

The diminishing birth rate is still exciting much attention, and the newspapers are seldom many days without letters on the subject. It appears pretty clearly that the economic reason is the chief one, determining the limitation of families. Women will not bear children to endure the evils of poverty.

OUR LETTER FROM CONSTANTINOPLE.

(From Our Special Correspondent.)

UNSEASONABLE WEATHER CONDITIONS—PLAGUE QUARANTINE—"DERATSATION"—RELAPSE OF THE CITY INTO FILTH—SMALLPOX IN ASIA MINOR—LEAGUE AGAINST TUBERCULOSIS—HOSPITAL NEWS—ANNUAL EXODUS TO THERAPIA.

CONSTANTINOPLE, May 1, 1904.

BUT for a scare of smallpox, which caused a rush for vaccination and revaccination, the winter's medical record of Constantinople has been singularly lacking in interest. The weather has been unusually rainy and raw, and even now the spring season is very backward. The large numbers of American tourists who came to Constantinople at this time of year must have been woefully disappointed at the miserable aspect of the Bosphorus and the city. In spite of rain, cold, and damp very little sickness has prevailed during the winter months. Ordinary catarrhal affections and cases of relapsing influenza have been most apparent.

The recrudescence of plague in Egypt has shown the Quarantine Department quite prepared for an emergency. The lazaretto at Clazamene has been well organized, and the general quarantine regulations cannot be considered now to press more heavily on the shipping than is absolutely necessary for the purposes of such institutions. The personal comfort of passengers and crews receives a larger amount of consideration than formerly. The recommendations of the Paris International Hygiene Conference appear to be carried out in detail. Rats and mice receive a full amount of attention, as may be judged from the telegram circular of the Superior Council of Health of April 27, 1904, to the health officers:

"*Par décision du Council Supérieur de Santé, en date du 26me Avril courant, les vaisseaux de guerre sont exemptés des prescriptions de la circulaire No.* 180 *concernant la destruction des rats et souris sur les navires, Mais le médecin du bord ou, à son défaut le commandant, sera tenu de délivrer a l'autorité sanitaire une déclaration écrite attestant qu'il n'a pas été constaté sur le batiment de mortalité parmi les rongeurs y existant possiblement. Au cas où une pareille déclaration ne pourrait pas être fournie, le médecin ou le commandant susdits s'engageront sur la demande de l'autorité sanitaire à faire exécuter la "dératisation" de leur bateau par les soins de l'équipage.*"

"*Deratisation*" is not the first queer word introduced into languages by quarantine departments.

The internal municipal health authorities, after making a creditable record of city hygiene, appear to have suddenly collapsed either from used-up energy or lack of funds—perhaps a little of both. Anyhow, the cleanliness of the city is gradually relapsing into what was considered a normal state of filth. The streets and alleys now nightly give forth superabundantly nauseous odors from the collections of household rubbish, which are permitted to lie soaking until they ferment. If these conditions be not speedily remedied there will be an outburst of gastro-intestinal affections, and a probable recrudescence of typhoid fever, from which the city has been comparatively free for the last two years.

It is stated that smallpox is steadily spreading in the Asiatic provinces of Turkey. It is probable that the recent epidemic at Smyrna has contributed to this, as the most stringent regulations on the part of the authorities could do little toward restricting the movements of a wandering Eastern population nor get them to practise cleanliness or disinfection, except of the most perfunctory kind. If "Irades" were effectual, contagious diseases would cease to exist in Turkey. Numerous as are these health "irades," they must be treated as paper plausibilities.

"La Ligue contre la tuberculose (phthisie pulmonaire) de Constantinople" is an imitative effort in the right direction, though it must necessarily—and for long—be looked upon as a purely academic attempt to propagate a practical knowledge of the means necessary to limit the conditions that tend to spread the disease. The object is stated to be to propagate amongst the public practical knowledge indispensable for preserving from tuberculosis by public conferences in the various synagogues, popular lessons in schools, by the members, by the publication of practical advice, for the prevention of this disease in language intelligible to the people, etc.; by the distribution, for the most part gratuitous, in schools of spittoons; by the distribution in schools,

pharmacies, etc., of tables (tableaux!) containing elementary advice indispensable to avoid and combat phthisis; by the formation of ambulances, especially in the populous quarters of the city, where medical consultations and the necessary remedies shall be gratuitously granted to the poor suffering from pulmonary complaints. This large program is to be carried out by the members of the league, named without distinction of religion, nationality, or sex. There are active, passive, corresponding, and honorary members. Thirty-two articles of regulations complete the organization of the league which for the moment will confine its efforts to the Capital and neighborhood. Cleansing Augean stables would be mild work compared with this attempt at sanitation in a place like Constantinople!"

The Military Medical School at Haida-Pacha is still in progress of organization. The new British Seamen's Hospital is near completion. Architecturally, it is not quite a thing of beauty externally, but the interior arrangements are good and up to date. The Coury-Yalova thermal station has been opened for the season, but the sudden death of the director may somewhat retard the operations. The "world" is beginning preparations for the summer, Bosphorus and Islands, season. At Therapia a large hotel is in progress of building, and will be ready for reception of visitors this season. Therapia continues as of old, and as the name implies, to be considered the hygienic village of the Upper Bosphorus, and the addition of the hotel arranged with reference to sanitation will be hailed with satisfaction by the numerous American and other visitors, who, for health and pleasure, sojourn there in yearly increasing numbers. The Medical Society has had an ordinarily useful session.

Progress of Medical Science.

The Boston Medical and Surgical Journal, June 9, 1904.

Carcinoma Basocellulare: A Group of Superficial Gland-like Tumors of the Skin, of Relatively Slight Malignancy, Including Rodent Ulcer.—S. C. Emley presents a table of thirty-five cases as well as a long list of clinical notes. Surgical intervention was sought, as a rule, only after the tumors had existed for a number of years. This was due to their seeming insignificance. The duration of the growths varied from forty years to two months and averaged over eight years. The average age of the patients was fifty-one years. Recurrence was observed in eight cases. Involvement of the lymphatic glands was invariably wanting. The tumors were all small, and in all cases were located on the upper forty-three of the face. The writer discusses three forms: The bulbous, the "cystic," the styloid. There is an almost universal tendency to consider these tumors as closely related to carcinoma. The writer regards the so-called "rodent ulcer" as belonging to the styloid form of this class of tumors. The development of these tumors from the basal layer of the epithelium, from hair follicles, or from the necks of the sebaceous glands, is definitely established. These tumors are not glandular, but gland-like; they are benign, superficial, and develop from the epithelium. Proliferation of the epithelium and invasion of the deeper tissue occur in the histogenesis of these tumors, and yet the majority of the clinical characteristics of carcinoma are absent. In connection with recurrent cases, the evolution to carcinoma often takes place as a result of methods of treatment largely due, doubtless, to their location upon the face.

A Case of Pregnancy in a Uterus Bicornis Unicollis.—Charles M. Green reports this case, which was carefully observed. The patient, while in the seventh month of pregnancy, began to flow profusely while sitting in a chair and in all lost a quart of blood. She was admitted to the hospital. The abdomen was large and broad. There was a large and well-marked medium sulcus, suggesting twin pregnancy. During a uterine contraction this sulcus became more marked and could be distinctly felt. Beginning just below the umbilicus, it extended upward, becoming broader and deeper and dividing the fundus uteri into two distinct and nearly equal parts. The part on the right was firm and resistant; in it the outline of the fœtus could be palpated and the fetal heart could be heard. The left cornu was less resistant; no part of the fœtus could be felt in it, nor could the fetal heart be heard over it, but a loud placental bruit was heard over this area. After the birth, there was felt on the left a mass of the size and feeling of a normal uterus during the third stage. To the right and closely connected with it, was a smaller mass, that part of the uterus, doubtless, which had contained the child. After forty minutes, pressure on the left side of the uterus easily expressed the placenta. There was no post-partum bleeding. The amniotic sac was partly divided into two parts. Exploration of the uterus by a sound, later, showed the depth of the right cornu to be four inches; that of the left, 4½ inches.

Journal of the American Medical Association, June 11, 1904.

The Prophylaxis of Tetanus.—S. C. Stanton makes the following suggestions: The manufacture and sale of toy pistols and other dangerous toys should be prohibited. All wounds in which there is, from environment, any possibility of tetanus should be treated by the open method. In case of wounds of a suspicious nature tetanus antitoxin should be made *immediately*, and continued upon the slightest manifestation of tetanic seizures.

Medical News, June 11, 1904.

Pathology and Treatment of Simple Fracture of the Patella.—Ellsworth Eliot, after a careful consideration of this subject, believes that the following conclusions are warranted: Owing to the not infrequent incontrollable rotation of the lower fragment, through an arc of 90 degrees on its horizontal axis, accurate apposition of the fracture surfaces cannot always be secured, and under these circumstances the ultimate result of conservative treatment could scarcely prove satisfactory. Suitable apposition may also be prevented by the interposition of torn shreds of capsule, by extravasated blood-clot and possibly also by the interposition of untorn periosteum conditions which can be recognized and remedied by exploration. Suture of the fragments permits of simultaneous suture of the torn capsule, a procedure of the greatest importance for restoration of joint security. The results of suture are almost invariably excellent, and the risk of operation is comparatively slight. The writer declares that in no way does he wish to belittle the risk of operation. The exercise of the most rigid aseptic precautions in all that pertains to the operation cannot be too greatly emphasized. If in any case there are reasons why the highest degree of surgical asepsis cannot be practised, it is far better to advise some non-operative procedure than to subject the patient to the possibility of a septic arthritis.

New York Medical Journal, June 11, 1904.

Constitutional Low Arterial Tension.—L. F. Bishop notes that there are some patients who give evidence on the most casual examination of the circulation, that the tension in the arteries is very slight, and in some this will be found to be a constant condition. It is surprising how little tension there can be in the radial pulse without the patient suffering from any symptoms of circulatory disease. Another and more important form is the low tension succeeding the high tension in chronic kidney disease. Here the circulation is no longer maintained by the heart. For the first named variety the most important element in treatment is systematic exercise. These patients are often dependent for their well-being upon regular physical exertion. Often they feel much better if they can take a brisk horseback ride every day or some other form of stirring exercise. There are other cases in which it is found that iron and arsenic improve the condition when it becomes very marked. In other cases very hot baths take the place of vigorous exercise and improve the tone of the circulation. It should be remarked that this is a secondary effect, because, if the circulation is examined immediately after the bath, it will be found to be more relaxed than usual. These patients do not react well, as a rule, to the cold bath.

Communities without Health Departments in the Crusade against Tuberculosis.—L. Flick refers to various conditions in communities under the circumstance named militating against the successful treatment of tuberculosis. One of the most serious difficulties is the unpreparedness of the medical profession for the task. Physicians have become persuaded that the disease is incurable and do not try to cure it. Experts must first be trained to care for these cases properly. This can best be done by establishing special dispensaries for the disease. Such dispensaries, however, must be equipped to give material aid, as well as medical advice. They must supply medicin, preventive measure supplies, and food when necessary, and they must supervise treatment in the homes of the patients through competent visiting inspectors. They must be equipped to give baths, sterilize clothing, and do laundry work, where these are necessary for keeping the home sterile. Next to these are required hospital accommodations for dying consumptives. These patients are not able to care for themselves, and it is during the last few weeks of life that they are especially dangerous. To make such a patient harmless means a constant cleaning of whatever has been soiled. A third necessary step is the establishment of sanatoria for curable cases needing comparative or absolute rest. All of these plans call for a great deal of money. The author suggests the enactment of a State law under which any town, county, or city may get a certain amount of State aid for work of this kind,

in proportion to the amount of work which the community itself does. Under such a law, if a community would establish an institution for the treatment of tuberculosis, it could draw from the State a certain amount of money in proportion to the amount of money raised for the purpose by the community; and for every patient treated it would get from the State a certain percentage of maintenance money for each day during which such patient was treated.

American Medicine, June 11, 1904.

Tuberculous Pericarditis, with Report of Cases.—Charles G. Stockton concludes that: Tuberculous pericarditis is not a rare affection. The diagnosis is usually not made except in cases with simultaneously active tuberculous processes in other parts. The concurrence of pleurisy with blood-stained effusion may be regarded as suggestive. The pericarditis may be of a chronic obliterative type, or there may be massive effusion, generally sanguinolent, but rarely purulent. It may be acute, cotinuing for but a few days, or chronic, existing for many months. It may be a part of a multiple serositis, and the proportion of cases in which at least one or more of the pleural cavities are involved is remarkable. The disease is to be regarded as a secondary affection, although from a clinical point of view, some cases may be looked upon as primary. The point of origin of infection is often found in the bronchial and mediastinal lymph-nodes, although these may be quite exempt from the disease. The infection may be direct from continuity of tuberculous tissue, or by transmission through lymph vessels or through the circulation. The heart may be greatly enlarged, or normal in size, or even somewhat small. Some observers believe that occasionally the process subsides and that comparative cure results.

The Lancet, June 4, 1904.

Pneumococcus Ulcerative Endocarditis Treated by Antipneumococcus Serum, the Pneumococcus Having Been Cultivated from the Blood.—A case of this nature is reported by T. J. Horder and A. E. Garrod, their patient being a man of twenty-six years, admitted to hospital with evidences of pneumonic consolidation in the lungs and endocarditis. A culture taken during life from the blood showed pure cultures of pneumococci, which were scantily evident in the sputa. Injections of antipneumococcic serum were at once begun. During its use, which was continued over several days, the range of temperature was somewhat lower than before, but there was no reason to suppose that any benefit followed the treatment. The autopsy revealed the lesions above indicated, and cultures from various organs showed the pneumococcus.

A Case Exhibiting the Adams-Stokes Syndrome.—E. E. Laslett gives the history of a woman of sixty-nine years. Up to the time the case was reported, the patient had had some thirty seizures. As seen by the reporter, the attacks were ushered in with unconsciousness, lasting about a minute, dilated pupils, gray cyanosis, stertorous breathing, rigid body, and irregular clonic movements of the arms. Recovery of consciousness quickly followed, the pupils contracted, the breathing became quiet. She sneezed violently, and then spoke to the bystanders, During the unconscious period, it was noted that the radical pulse was absent. No pain had been noted previously to any of the attacks. They usually came on without any warning, but sometimes they were preceded by faintness, or occasionally by a peculiar feeling as if someone were pressing on her chest and forcing her down. The urine was never passed during a fit. Consciousness, as a rule, returned very rapidly, and this was the more striking because at the height of the attack the peculiar cyanosis, the widely dilated pupils, the dull cornea, the dropped jaw, and the cessation of breathing would lead almost anyone seeing the condition for the first time to say that the patient was dead.

Removal of the Semicircular Canals in a Case of Unilateral Aural Vertigo.—The patient of R. Lake was a woman of twenty-one years, who had been subject to attacks of aural vertigo, with sickness and vomiting, with gradually increasing deafness and tinnitus for five years. All sorts of remedies were used, but gave no definite relief. Operation was decided on. An ordinary radical mastoid operation was performed, with the exception that the innermost portion of the posterior wall was not removed, but the bony opening in the temporal bone was enlarged, forward, upward, and backward. Anteriorly it was extended into the base of the zygomatic process of the temporal bone, and postero-superiorly in such a way that the long diameter of the bony wound was from above downward and forward. The malleus and incus lying exposed after the removal of the external attic wall were removed. At this period of the operation the burr was substituted for the cutting gouge, which had been previously employed. The next step in the operation consisted in exposing the upper and outer surfaces of the external semicircular canal in its whole extent. The antero-external portion of this canal was now followed forward and inward until the outer surface of the superior canal was brought into view. The whole of this canal was then removed by cutting it away with a medium-sized burr, leaving only the upper part of the arch or fornix untouched. The posterior rim of the external canal was then followed so as to bring into view the posterior canal. which was burred away entirely. A large oval burr was now substituted for the medium-sized one previously used, and the upper surface of the external —the only remaining canal—was cut away with the burr until the anterior half of the membranous canal was exposed. This was then removed with a small burr, which was afterward employed to make a medium-sized opening into the vestibule, and an attempt was made to clean away the crista acustica at that end of the canal. Immediate recovery from the operation was prompt. Certain disturbances of equilibrium, at first manifest, gradually cleared away. Fourteen weeks later the patient was free from vertigo and in improved general health.

British Medical Journal, June 4, 1904.

On the Alleged Transmissibility of the Malaria Parasite from Mother to Infant.—M. Grabham has carefully examined the blood of a number of pregnant women near delivery. Blood films taken from the infants stained by the Romanowsky method and submitted to prolonged and repeated search showed no trace of parasites, nor did they give any other indications of malaria, such as melanin granules in the leucocytes. In the blood of four of the mothers, numerous malaria parasites were found. The temperature of the infants showed no abnormal variations. All of the infants were somewhat feeble. Quinine was entirely withheld from the mothers while these observations were being made.

Essential Similarity of Innocent and Malignant Tumors.—Charles W. Cathcart presents the following conclusions: Every type of tumor has associations with malignancy, no class being exempted. The more highly organized and formed the tissue of a tumor, the more it belongs to the simple class, and *vice versa*. All forms of connective tissue tumors seem to converge to the round-celled sarcoma type, and all forms of epithelial tumor to converge to the encephaloid cancer type. Many tumors are characteristically malignant, although considerably removed from the extreme malignant structure. Mere structure of cells does not necessarily indicate clinical behavior. No theory of tumor growth can be considered satisfactory which would not apply equally to innocent and malignant tumors. The view of abnormal growth is consistent with many apparently inexplicable statements as to the behavior of malignant growths. The life of the tumor cells may be more precarious in some ways than those of the normal tissues, and so spontaneous subsidences may occur, or, again, tumor cells may be injured by toxins, *x*-rays, or even by mental influences. Mental influence may explain the effect of many vaunted cancer cures, all probably useless in themselves, except so far as they may affect the mind of the sufferer. It is doubtless best, in classifying tumors, to divide them primarily according to the type of tissue or organ from which they arise, and in each class to arrange the individuals according to the degree of malignancy which they manifest.

An Address on Arterial Sclerosis and Hypertonus in Their Relation to Diet and to the Digestive System.—William Russell declares that the two factors, arterial contraction or tonus and blood-pressure, must be kept rigidly apart, and yet both must be recognized and estimated. A third point in this regard is the determining whether a thickened artery is thickened from hypertonus or from arteriosclerosis. Hypertonus is not confined to people in middle and later life, for it occurs often in early life, but adaptability, elasticity, and endurance are greater then, and there may be no symptoms complained of. Hypertonus in vigorous people leads at once to heightened blood-pressure and raised arterial tension. But hypertonus also occurs in people whose hearts are *not* vigorous. A temporary excitement gives increased cardiac action and raised blood pressure, but as soon as the one subsides the other disappears. In such cases thickened arteries are associated with a low blood-pressure, for they have no margin of reserve in their hearts. The thickened artery is looked upon as arteriosclerotic. But it must be remembered that thickened vessels may owe much of what may appear to be structural thickening to hypertonus. In the case of a person with good appetite who suffers from a "bilious attack," it is well known that his arterial tension is raised. This is probably always associated with hypertonus. The heightened tension is not due to deleterious substances acting directly on the

heart. The primary and initial influence is on the vessels. The writer then considers hypertonus without increased blood-pressure. The writer believes that when gastro-intestinal morbid conditions cause hypertonus, we are face to face with the first step in the development of the sclerotic changes which are so common in middle and later life. In many people, the writer believes, indigestion and constipation lead slowly but surely to vascular changes. An excess of proteid food becomes a potent source of autointoxication. The reduction in quantity of the more pure proteid food with an increase in the more pure carbohydrate food is the necessary change. The latter food is mainly provided by the cereals.

Deutsche medizinische Wochenschrift, May 26, 1904.

Serum Diagnosis of Typhoid Fever by Ficker's Method.—Gramann has made some practical tests with this method in which the living typhoid culture is replaced by a specially prepared fluid. In twenty-five healthy persons the blood was tested and the results in every case were negative. In other persons ill with various diseases, but who had never had typhoid fever, the results were also invariably negative. In two doubtful cases of typhoid fever, the reaction continued to be positive even with a dilution of the serum of 1:2000, but in others a result was obtained only with a dilution of 1:100, or 1:50. Tests were also made with other immune sera (cholera and dysentery) and found negative. The author claims that this method affords a reliable and safe test which may be applied outside the laboratory and without the necessity of having an incubator or a microscope.

The Circulatory System and the Curability of Tumors.—H. Ribbert of Göttingen attempts to show in this paper that the nutrient blood does not enter into close physiological relation with neoplasms, and for this reason the latter become more readily subjected to sources of harm from without than normal tissues. Tumors, in contrast to normal organs, are not regularly supplied with normally constructed vessels. The latter are neither arteries nor veins, but simply tubes, in great part made up of endothelium, and unable to exhibit any changes in the blood pressure. These tubes do not branch in a regular manner, but constitute a network of interlacing canals, from which the efferent vessels collect the blood without regard to any definite rule. The size of these blood-vessels, when their total area is considered, is entirely out of proportion to the amount of tumor tissue supplied by them. Thus a large pedunculated growth may be nourished by a comparatively small vessel. It has also been observed that numerous sacculations and dilatations occur in the course of the vessels, and this condition must necessarily contribute to a slowing of the blood current. He accounts for the rapid increase in size of the neoplasms by assuming that the nutrient materials from the blood are entirely taken up by the tumor cells for growth and reproduction, as nothing is necessary for any other functionating processes.

Berliner klinische Wochenschrift, May 23, 1904.

Pentosuria as a Family Anomaly.—M. Vial reports three cases of this quite rare condition occurring in the members of a single family. All these had been diagnosed as diabetic, probably for the reason that the methods of detecting a pentosuria are usually considered too elaborate and difficult. The diagnosis can be readily made with the reagent already described by the author (*Deutsche medizinische Wochenschrift*, No. 27, 1903).

Value of the Examination of the Cerebrospinal Fluid for the Diagnosis of Nervous Disease.—E. Siemerling reports on a series of examinations made in the clinic at Kiel, in which attention was paid not only to the histological features, but also to the physical and chemical properties. It has already been proved that a lymphocytosis in the fluid was indicative, when taken in connection with other symptoms, of meningeal irritation. Among thirty-eight cases of progressive paralysis examined a well-marked lymphocytosis was found in thirty-seven, and the author believes as it appears in the early stages of the disease, it may be considered one of the early symptoms. In epilepsy and simple melancholia, negative results were obtained. In one instance of religious mania, a very slight increase in the number of lymphocytes was noted. A well-marked lymphocytosis was present in all cases of organic nervous diseases, which was absent in pure neuroses and dementia apoplectica. In a case of extradural hemorrhage, the red color with which the cerebrospinal fluid was tinged remained after the specimen was centrifuged. In another case in which the bleeding took place into and broke through the floor of the third ventricle, the fluid remained clear after the blood had settled to the bottom of the tube.

Lipomatosis as a Sign of Degeneration.—E. H. Kisch calls attention to the view that lipomatosis is not a disease *sui generis*, but merely a symptom of a variety of bodily disorders, among which he discusses in this paper that of hereditary degeneration. He has already described a number of years ago the presence of characteristics in certain children which may be stated to be masculine attributes in girls, feminine attributes in boys, gigantism, and premature sexual development. The connection is not, however, universal, and it is necessary to distinguish between hereditary and acquired adiposity, and also between the hereditary form which comes on during early youth and that which comes on later in life and is influenced by pathological causes. He has closely observed 488 cases, which he has grouped into four classes on this basis. From a study of these he believes that when a lipomatosis of a well-marked degree is present from early childhood, it must be looked upon as an example of hereditary degeneration and is invariably associated with other stigmata of degeneration. This cannot be maintained, however, for the acquired, or for that form of hereditary adiposity which does not become marked until later in life. It was also found that in all cases of lipomatosis which are of that type which begins very early in life, diabetes mellitus is seen to develop sooner or later, usually between the ages of thirty and forty. In the cases in which the affection does not develop until later in life, only about one-half the patients become afflicted with diabetes, while in the acquired form about 15 per cent. become affected. Sterility is also a common attribute of this condition.

Münchener medizinische Wochenschrift, May 24, 1904.

Surgical Treatment and Histology of Röntgen-ray Ulcerations.—Baermann and Linser found that extensive areas of facial lupus were more completely cured when a pronounced reaction attended the use of the *x*-rays, rather than when the reaction was mild. In a number of cases, however, there were severe ulcerative processes which could not be healed by ordinary measures. Good results were secured by transplanting pediculated skin flaps, the Thiersch method proving entirely ineffective. Eight cases are reported which were thus treated with excellent results. Histological examinations of specimens taken from the ulcers produced by the rays show that the latter have their principal effect apparently on the blood-vessels, which are damaged and destroyed. There is therefore, as it seems, no selective action on the epithelium. Such a process, however, would account for the gangrene of the lower lip, which was noted in one case as the result of the application of the rays. Proliferation from the edges readily took place in these ulcers, but the lack of granulation tissue for it to grow upon, from defective or destroyed blood-vessels, prevented its further extension over the raw surfaces.

Pyæmia Running a Chronic Course.—O. Jordan of Heidelberg reports a case which differs from those ordinarily described as chronic pyæmias. The patient was a young man of twenty who developed an acute pyæmia from a furuncle in the neck. This was followed in about two weeks by a localization of the process in the right kidney, with the appearance of severe septic symptoms, which were thought to be due to typhoid fever. A perinephritic abscess finally resulted, which at the operation was shown to have developed from foci in the cortex of the kidney. The patient convalesced, but the suppurative process in the kidney continued and a nephrectomy had to be done, after the elapse of several months. As the result of the patient's toxic condition, a nephritis had meanwhile developed in the other kidney. For several months abscesses developed in the soft parts of the legs, which ran their course without causing any general disturbances. Later still an osteomyelitis developed in the fifth dorsal vertebra, accompanied by a pachymeningitis and subdural suppuration, with complete paralysis of the lower extremities. During all this time the staphylococcus albus could be demonstrated in pure culture. Chills and remittent or intermittent fever were not present and cannot be accepted as a characteristic train of symptoms for pyæmia. The author claims that the diagnosis must rather be based on the metastatic formation of abscesses or inflammations developed by hematogenous routes.

Dysbasia Angiosclerotica.—W. Erb of Heidelberg described several years ago a complex of symptoms characterized by intermittent limping gait and sensory and circulatory disturbances in the foot and leg. Thus far he has observed forty-five cases, most of which show the typical symptoms, while in the atypical minority the signs may be less marked or constant. The condition may be present in one or both legs and one of the most constant symptoms was the loss of pulse in the arteries of the foot. In thirty cases the affection was double, in the remaining fifteen unilateral. Arteriosclerosis in varying degrees accounted for the circulatory disturbances, but

only one instance of contracted kidney was observed and the presence of albumin was proved in but two cases. Vasomotor disturbances were present in most cases, marked usually by cold feet, but sometimes by anæmia, cyanosis, etc., which could be demonstrated objectively. The diagnosis is easy and should be based on the absence of spinal symptoms and the lack of pulsation in the foot. Gangrene was seen in two cases, and the author thinks that it is important to make an early diagnosis to avoid this complication if possible. Nothing new has been determined as to the etiology. The affection is found almost exclusively among men over forty years of age. Syphilis and alcohol did not appear to play any important rôle, but he is inclined to attribute much to the misuse of tobacco. Exposure to cold also seemed to play a part in the etiology of some of the cases. The treatment is largely dietetic, hygienic and tonic, and no new recommendations are made.

French and Italian Journals.

Cardiac Thrombosis in Pulmonary Tuberculosis.—Ernest Barié speaks of intravascular blood coagulations as being very common in pulmonary tuberculosis, especially in the cachectic period. The heart itself does not escape this serious complication. So grave a condition allows of only simple treatment—palliative measures; absolute quiet stands first of all. The suffocation crises should be treated by subcutaneous injections of sulphuric ether, morphine, or heroin, and by inhalations of oxygen. It is important to prevent the thrombus from becoming the point of departure of secondary embolism. For this purpose it is necessary to quiet and regulate the tumultuous action of the heart by a little digitalis.—*Journal des Praticiens*, April 23, 1904.

A Severe Case of Secondary Syphilis Treated by Endovenous Injection of Sublimate.—Antonio Amenta treated this case by the abortive method of Tomasoli. The patient was a male of forty-five years of age. From May to September he received twenty-two injections of sublimate. At the end of this time he had headache, nocturnal pains, iritis, and conjunctivitis. The following February found him with a severe pustular syphilide which had ulcerated in many locations of the body. He had fever, general malaise, was emaciated, had frequent pulse, and obstinate constipation. Fetid pus flowed from the nares. After purgation he received daily endomuscular injections of calomel, 5 cgm. The improvement was immediate. Later, sublimate was substituted by endovenous injection, one per cent. solution, on alternate days. He also took biniodide of mercury. The result was a rapid and entire cure.—*Giornale Medica del Regio Esercito*, March 31, 1904.

On the Vitality of the Bacillus of Influenza in Moist Sputum.—Pietro Ricciardi has made experiments as to the length of time during which the bacillus of influenza will retain its vitality in moist sputum. In cultures made on solid media it soon loses its vitality. In sanguinolent broth it lives from fourteen to eighteen days. In water it soon dies. When they become dry their life is not longer than eight to twenty hours. They seem to be spread mainly by the moist sputum ejected with the cough. In the author's experiments the sputum was taken from the patient, immediately examined for the bacilli of Pfeiffer, and cultures made. After some days, a fresh examination and culture were made, and this was continued until the vitality of the bacilli was past. They were maintained under the most natural conditions that could be attained. The writer concludes that their vitality lasts from ten to twelve days when kept at 15° to 19°, from six to eight days at 25° to 26°, and for three days at 37° to 38°. The bacilli are destroyed as soon as saprophytes grow in the sputum, and whatever favors the growth of the latter is injurious to the bacilli of Pfeiffer. Ricciardi believes that the propagation of influenza at a distance must be rare.—*Giornale Internazionale delle Scienze Mediche*, April, 1904.

Sclerosis of the Coronary Arteries.—Ettore Marchiafava, writing of sclerosis of the coronary arteries, divides the disease into five varieties: (1) Simple sclerosis of the coronary arteries without grave alterations of the myocardium; (2) sclerosis of the coronary arteries with acute or chronic lesions of the myocardium; (3) grave stenosis of the orifices of the coronary arteries without sclerosis of the arteries or myocardial changes; (4) old obliteration of one coronary artery at its mouth without myocarditis; (5) acute obliteration of one large branch of a coronary artery, with anæmic infarct or myomalacia, with or without rupture of the heart. In group first, simple sclerosis, there are attacks of cardiac asthma at night, or of angina pectoris for some time before death, from pulmonary œdema. In group two, where there are myocardial lesions as well, death is preceded by a longer or shorter period of suffering, due to progressive insufficiency of the muscle. In a case observed by the author there were sudden hemorrhages into the heart muscle, causing immediate cardiac paralysis. Group three occurs in syphilitic subjects, and comes on slowly, death not being sudden. In group four, the lesion comes on gradually and a compensatory circulation is set up. In group five, acute obliteration of a large branch of the coronary artery may occur suddenly by thrombosis or embolism.—*Rivista Critica di Clinica Medica*, April 23, 1904.

Congenital Malformation of the Œsophagus (Œsophageal Obliteration and Œsophago-tracheal Communication.)—Jules Renault and Jules Sebilleau discuss the diverse malformations of the œsophagus: Transposition, coincident with the complete or partial transposition of the splanchnic organs; duplication; complete absence; transverse partition or imperforation; communication with the trachea. The last two are the most frequent, and are often associated. Obstruction of the œsophagus is almost ignored. Regurgitation, the only symptom which attracts attention, can be interpreted in very different ways, and one does not dream at first of œsophageal malformation. Catheterism of the œsophagus, a very easy operation in the child, will determine without error the existence and the location of the obstruction. The writers then describe their case. For this trouble they believe there is one logical operation—that of gastrostomy. This is, however, most difficult in a young infant, considered in all its aspects. But, however slight the chances of intervention, it is legitimate if one only feels that there is hope in it.—*Le Bulletin Médical*, May 25, 1904.

A Rare Case of Infective Splenic Anæmia.—Andreo Pitini describes a rare case of splenic anæmia in a baby of two and one-half years, of healthy parentage, and well, up to the beginning of the disease described. The child began to have fever, to grow pale and lose flesh, and to have œdema of the face and feet, at the same time that the abdomen began to enlarge below the costal arch on the left side. His gums were swollen and eroded, and bled easily. All the abdominal organs appeared to be normal except the spleen, which was markedly enlarged, extending from the ribs to below the level of the umbilicus. There were no enlarged glands. The blood examination showed the leucocytes moderately increased in number. In the blood from the spleen, liver, heart, and veins was found a pure culture of a diplococcus. The brother of the patient, aged eight months, also had an enlarged spleen and increase of leucocytes. The author states that Fich believed splenic anæmia to be due to infective germs which caused toxic substances to be elaborated by the spleen, and these produced the progressive anæmia. Concetti believed it to be secondary to some acute infection, such as rheumatism, malaria, syphilis, tuberculosis, a gastroenteritis, or rachitis. The products of these infections were carried to the liver by the circulation and produced the anæmia. In the author's case these could all be excluded, and he believes it to have been due to the diplococcus found in the blood. —*Gazetta Medica Lombarda*, March 28, 1904.

Trophic and Circulatory Disturbances of the Skin Resulting from Injections of Paraffine.—Dionis Séjour recounts the history of an interesting case in point: A young woman had injected paraffine into her breasts in order to make them more full. The mixture of paraffine and vaselin which she used was analogous to that of Gersuny. The first injection was so painful, that the patient was obliged to stop the operation. The pain was followed almost immediately by tumefaction, redness of the skin, and tenderness of the axilla. Three weeks later, injections were made into both breasts without any reaction. At the end of fifteen days intermittent pain developed on the right side, followed soon by a change in the color of the skin, which became violet-colored in spots, while a sinking in of the breast showed diffusion of the injected material. At first, inflammation was thought to be the cause of these phenomena, but treatment for the same met with no response. Two incisions were then made, and as much as possible of the foreign matter pressed out. There was no pus. At the end of a month, the wounds which had a varnished aspect, were retracted, but there had never been any inflammatory reaction. There was a little trouble on the left side, but never as marked as on the right. The persistence of the troubles in spite of treatment, and the absence of inflammatory phenomena, certainly point to the existence of trophic and circulatory troubles, due no doubt to the penetration of particles of the injected mass into the blood system. Injections of paraffine are not so innocent as is sometimes supposed, and should, like every other surgical operation, be reserved for necessary cases.—*Gazette des Hôpitaux Civils et Militaires*, April 19, 1904.

Society Reports.

AMERICAN MEDICAL ASSOCIATION.

Fifty-fifth Annual Meeting, Held in Atlantic City, N. J., June 7, 8, 9, and 10, 1904.

(Special Report to the MEDICAL RECORD.)

(Continued from page 988.)

HOUSE OF DELEGATES.

Fourth Day—Thursday, June 9.

Adoption of the Resolution in Regard to Wood Alcohol.—Dr. J. N. McCORMACK of Kentucky said that the reference committee reported favorably on the resolution that as the employment of wood alcohol had been responsible for a large number of deaths and many cases of blindness, and as even confined fumes might cause blindness, the committee on legislation should secure action designating this substance as a poison and regulating its sale. This resolution was unanimously adopted.

The Scientific Exhibit.—Dr F. B. WYNN of Indianapolis reported that this exhibit had been introduced as a feature of the American Medical Association four years ago. It consisted of subjects illustrating the work of the various sections. The present exhibit surpassed any previous one both in artistic work and in size. Research exhibits were desirable, but did not constitute the prime object of the exhibit; they wanted such work as would be instructive to the great rank and file of the profession. In preparing the exhibit a wholesome rivalry among different cities had been aroused, and several instances were related which served to illustrate the advance that had been made in the artistic work of the various exhibits. Few institutions had creditable museum specimens for teaching purposes, and the work of the American Medical Association had started up considerable activity in this direction. Competent demonstrators were present at certain hours daily, in order to explain the exhibits.

Invitations to Appoint Delegates.—Dr. JOHN H. MUSSER read invitations to the American Medical Association asking that they appoint delegates to the International Congress at Bordeaux, and the X-ray Congress at Berlin, and from the International Congress of Medicine asking them to organize for representation in this country. These invitations were accepted, and the president said that delegates would be appointed later.

Recommendation of the Section on Dermatology.—Dr. MUSSER read a recommendation from the above-named section, suggesting that the American Medical Association, in view of the United States having acquired possessions where leprosy existed, should urge upon the federal authorities the necessity for a hospital and laboratory accommodations in such localities for the study of this disease.

National Legislation.—Dr. C. A. L. REED of Cincinnati, Ohio, reported that his committee favored the resolution, endorsing the action of the Postmaster-General in respect to the use of the United States mails for the distribution of literature and drugs intended to deceive the public. The House adopted this resolution.

Report of Committee on the Establishment of a National Bureau of Medicines and Foods.—Dr. E. ELLIOTT HARRIS of New York reported that the committee had decided to lay the matter before the House of Delegates as they were unable to come to a decision. This resolution asked for the establishment of a bureau of medicine and foods, which should pass upon the purity, identity, quality, strength, etc., of foods and drugs, in order to protect physicians and pharmacists and the public from all doubtful or harmful compounds.

Dr. MOYER of Illinois said that a national bureau of food and drug registration already existed, and that on account of the vastness of the proposition it was not practicable. Such a measure, in the form of the Hepburn Bill, was already before Congress. He thought that the best thing the American Medical Association could do along this line was to urge Congress to give us adequate legislation.

Dr. PHILIP MILLS JONES of California said that he had obtained the opinion of competent lawyers, and they had informed him that the formation of such a bureau would not interfere with national legislation, but would help it. He had said that it was the opinion of Dr. Wiley of the Department of Agriculture that such a bureau would supplement the national work.

After a prolonged discussion along these lines, the committee finally recommended to the House of Delegates that the matter be indefinitely postponed. This recommendation was agreed upon.

Committee on Reapportionment.—Dr. W. S. FOSTER of Pittsburgh said that the House of Delegates would consist next year of 150 members as at present, that was one member to every 500 physicians, including delegates from the army, navy, and marine hospital service and the different sections of the American Medical Association. He then read the apportionment by States.

Committee on Section and Section Work.—Dr. M. L. HARRIS of Illinois reported that they could not recommend the appointment of a permanent committee on section work.

Report of Committee on National Incorporation.—Dr. JOSEPH D. BRYANT of New York presented a petition for presentation to Congress setting forth the objects and aims of the American Medical Association and asking that a charter be granted them by special act of Congress. A copy of this petition was given to a delegate from each State in order that he might get the signatures of the members of the profession in his own State.

Election of Officers.—The following were elected officers of the American Medical Association for the ensuing year: *President*, Dr. Lewis S. McMurtry, Louisville, Ky.; *Vice-Presidents*, Drs. J. H. Bell, Texas; Edward Jackson, Colorado; F. C. Shattuck, Massachusetts; B. F. Pennington, New Jersey; *Secretary*, Dr. G. H. Simmons, Chicago, Ill.; *Treasurer*, Dr. Frank Billings, Chicago, Ill.; *Members of the Board of Trustees* for three years, Drs. T. J. Happel, Tennesee; W. W. Grant, Colorado; Philip Marvel, New Jersey. Drs. A. Maitland Ramsey of Glasgow, Scotland, and A. Logan Turner of Edinburgh, Scotland, were elected honorary members of the association.

Addresses at the general meetings of the association next year will be as follows: General Medicine, by Dr. Charles Stockton of Buffalo; Surgery, by Dr. John Collins Warren of Boston; State Medicine, by Dr. George Brannan.

Portland, Ore., was decided upon as the place of the next meeting, in June, 1905.

GENERAL SESSIONS.

Third Day—Thursday, June 9.

Oration on State Medicine.—Dr. HERMAN M. BIGGS of New York delivered this oration (see p. 954).

Symposium.—"The Departments of Scientific Research of the United States Government."

The Bureau of Animal Industry: Its Service to Medical Science.—Dr. Wm. H. WELCH of Baltimore considered this subject. The object of the Bureau of Animal Industry, established in 1884, was to further the interests of this industry by the study and control of the diseases of animals that occasioned the greatest losses. Animals were affected by disease very much as human beings, and the pathology of animal and human disease is identical. Such being the case, the study of diseases of animals threw much light on the science of medicine. The scientific researches of the staff of this bureau, had resulted in the eradication of pleural pneumonia, and the foot and mouth disease. This was affected by killing both the diseased animals and those that had been exposed to infection. They had discovered the bacillus of hog cholera,

the microorganism of Texas fever, a protozoan parasite, which wash was conveyed by the cattle tic. They had investigated the subject of rabies, which was not so common in animals as has been supposed. Measures had been taken to exclude the introduction of Oriental animal parasite into this country. Animal tuberculosis had been a subject of investigation for over ten years. To their researches could be credited the discovery that immunity in cattle could be obtained by injecting attenuated cultures. They had investigated Koch's theory and had proved that cattle could be infected by human beings, and it was now supposed that the reverse might be possible. The American Medical Association should exert its influence to the end that the government might take a greater interest in the study of human diseases than as it had shown in that of animal disease.

The Service of the Medical Profession to the Bureau of Animal Industry.—Dr. D. E. SALMON of Washington, D. C., said that in his connection with this work for a period of twenty years he had felt the need of support and encouragement that could be given from outside sources. He said that this department maintained places of inspection of all animals used as food and of all those coming into or going out of this country. In large lavatories, all animals were inspected both before and after killing. The immense work involved could be appreciated when it was known that 37,000,000 head of cattle were inspected annually, and the cars employed in their transportation disinfected. This work naturally met with enormous competition from commercial interests. Conscience and philanthropy seemed to have no place in commercial life. A never-ending battle was being waged with a class of people opposed to experimental work on animals, who entirely lost sight of the great end attained in the saving of human life and vast sums of money. The freedom of the investigator must be preserved if the importance of the problem of obtaining a pure and abundant food supply, and of contributing to medical science much that was of value. The medical profession should support this work by aiding the Bureau of Agriculture in securing the right to use the most effective remedy for the eradication of disease and the right to produce pure immunizing agents, and also to throw its moral support on the side of science and philanthropy in its conflict with commercialism.

The Bureau of Chemistry and Medical Science.—Dr. W. H. WILEY of Washington, D. C., said that a close relation existed between the problems studied by the Bureau of Chemistry and Medical Science. In regard to the disposal of waste material, he said that samples of garbage of all kinds had been collected, and their value as a fertilizer had been investigated. The fertilizing elements were separated in factories for this purpose. He thought that the time would soon come when no city would dump its sewage into a river for the use of some other city. They had experimented with sewage in regard to its usefulness for agricultural purposes. Some progress had been made, but he could not say that the experiments had been completely successful. This was a problem for the future. An investigation was being carried on with reference to dyes and other chemicals used in the manufacture of clothing materials with a view to finding out what effects might be produced on human health. They had examined almost every kind of human food for adulteration. He called special attention to the general use of meat preservatives, especially the sulphites of soda. All imported foods were analyzed, and those containing injurious substances were branded so as to deceive the public, or such as were not permitted to be sold in the countries where they were manufactured were condemned and denied entrance into the country. It was found that much of the imported white wine was a saturated solution of sulphurous acid. This was only an instance since the first of last July out of 2,000 cargoes, 10 per cent. were forbidden entrance into the United States. The Bureau of Chemistry also endeavored to assist the State in their fight against local food adulteration. They inspected drugs, both imported and domestic. At present they were assisting the post office in its endeavor to exclude secret remedies and their literature from the mails. Here terrible opposition would be encountered both from the manufacturers of nostrums and the whiskey trust. Eighty-five per cent. of supposed whiskey sold in this country was not whiskey; in the course of one day from one barrel of pure alcohol, two or three barrels of liquor could be manufactured which were reported to be whiskey ten years old. The American Medical Association could exert its influence with legislative bodies in securing proper legislation in this matter.

The Work of the Marine Hospital Laboratories.—Asst. SURGEON H. C. GEDDINGS related the history of the Marine Hospital laboratory from a small beginning at Stapleton, S. I., in 1887, to the present time, when they were erecting a new laboratory in Washington, at a cost of $35,000. Here they had an excellent school for the instruction of their officers. They had investigated the subject of disinfection, had exploited formaldehyde, and had elaborated and perfected apparatus for the purpose of disinfection. The first authoritative publication on diphtheritic antitoxin in this country. They had instituted means for protecting the country from the introduction of plague. Eighteen reports, in the forms of bulletins, had been published, and others would soon be complete. They had demonstrated the presence of tetanus in commercial jelly, and had studied spotted fever and hook-worm disease. Under their inspection the purity of serums, and especially of vaccine, had been greatly promoted. They lent their assistance in times of epidemic, studied the etiology of yellow fever, and were working on the problem of the proper sanitation of railroad coaches and cars. Such a wide and varied work must necessarily give much to the medical profession, and in return should receive the support and assistance of the American Medical Association.

SECTION ON SURGERY.

Second Day—Wednesday, June 8.

Twine in Lieu of the Elastic Ligature for Performing Gastroenterostomy.—Dr. J. W. DRAPER MAURY of New York City detailed the history of work done in an experimental line during the past winter at the Surgical Laboratory of Columbia University. He described the twine triangular stitch in place of the square, being a modification of McGraw's method, and depending on a somewhat different principle for its efficiency. He showed the advantages of the use of twine over elastic, the degeneration of the latter from contact with air being well known. The life of an elastic ligature does not exceed six weeks or at most two months under the most favorable conditions. Strong white commercial twine, which will not break with the hands, can be easily obtained anywhere, and can be introduced with less difficulty than the elastic. Any large needle will carry the twine, while varieties of complicated needles have been made to facilitate the use of the elastic ligature. Three months ago Dr. Maury said twine was substituted for elastic ligature, and the triangular stitch used instead of the quadrangular, since which time thirteen dogs have been operated upon, the stomachs and intestines of all of which had been brought to this meeting and placed upon exhibition. It had been shown that this stitch invariably produced a large and commodious opening. He said they operated upon a pig and a very perfect specimen of enteroenterostomy was obtained, it having been removed after the pig had lived for six months; this specimen was also brought to this meeting for exhibition. As this gut resembles that of man more than dogs, more satisfactorily experimental results can be obtained. He stated the introductoin of the twine could be accomplished in less than a minute and a half, but like

every other stitch required some study and practice—he demonstrated between two hats the ease with which the stitch can be inserted. Dr. Maury described the method of inserting the twine in triangular form, which was illustrated by a chart Dr. Weir had had made for the purpose. He said the Lembert stitches were certainly necessary in the technique, although it did not appear to matter whether they were interrupted or continuous, but the former was generally employed. Dr. Maury said that by some it might reasonably be felt that not enough work had as yet been done in an experimental line to demonstrate positively the efficiency of the twine ligature, and the twine is at least the equal to elastic, if anything could be judged from a small but consecutive series of successful experiments.

Remarks on the Disadvantages of the Murphy Button.—Dr. ROBERT F. WEIR of New York opened this paper by stating that he did not propose to decry the merits of the well-known Murphy button, for it was conceded by every one to be an admirable mechanical device, but since its introduction an enormous experience as to its value had been acquired, which it was well from time to time to take stock of. He referred to the great saving of time by the use of the button, and particularly if one avoided using any sutures of safety to hold together the peritoneal surfaces peripheral to the button, which, however, were from time to time found to be an additional necessity. He referred to the various mechanical devices in use previous to the introduction of this button and commented on their various merits, but admitted that the button was an improvement over all of them. He then detailed some of the mishaps which occur from time to time in the use of the button, among others the occasional escape of the button into the stomach, the failure of the button to come away, the imperfections in its manufacture, and the various materials of which it was made, and explained certain methods of his own for overcoming these drawbacks. He alluded to the objection that both surgeon and patient felt at leaving within the body a metallic device with the imperfections that were inseparable from any mechanical contrivance, and said it was not to be wondered at that many surgeons of distinction both here and abroad should have recently reverted to the previously cast off simple method of incision and suture. He spoke unfavorably of the oblong button which had lately been applied to a gastroenterostomy by Murphy and Blake, as he believed there was a greater risk of lodgment in the stomach and an increased amount of variety of mechanical contrivance. He was more hopeful of the elastic ligature suggested by McGraw of Detroit.

Excision of the Ulcer-bearing Area in Gastric Ulcer.—Dr. WILLIAM L. RODMAN of Philadelphia considered that this was the most rational method of the treatment of this condition, other methods being not infrequently very disappointing. He admitted that excision of the ulcer alone might not cure, as in at least 20 per cent. of all cases the ulcers were multiple. He drew attention to the fact that gastroenterostomy at times utterly failed to control hemorrhage and prevent perforation and always failed to remove cicatrices which might degenerate into carcinomata. He did not believe that the mortality following excision of the ulcer-bearing area would probably be any greater than the medical treatment of gastric ulcer or the less radical surgical procedures already established. In addition he claimed that this method left the stomach in better condition for future usefulness.

Dr. A. J. OCHSNER of Chicago said he would limit his discussion entirely to the McGraw ligature. His experience covered 86 cases, 68 of which were operated upon in the hospital, while the balance occurred in various places where it was not possible to observe them so closely. Of the 68 cases done at the hospital, 19 were for carcinoma of the stomach, in which he did a simple gastroenterostomy for the relief of the obstruction of the pylorus. Of these cases 3 died, but he believed such would have been their termination, even had he not used the McGraw literature. In 12 cases of benign stricture of the pylorus due to healed ulcers, all recovered. Thirty-three cases were operated upon for acute ulcer of the stomach, of which 32 recovered, 1 dying at the end of the third week from probable thrombosis of the pulmonary. He also reported one successful enteroenterostomy for a carcinomatous obstruction of the splenic flexure of the stomach with recovery, 2 enteroenterostomies, of which one died, probably from depression and one operation for carcinoma involving the common duct. Of intestinal cases he reported 67 with 5 deaths, of which 3 were due to carcinoma, one to a thrombus, and one to a very greatly depressed condition of the patient. He detailed a case operated upon about two weeks ago in which he did a gastroenterostomy and excited about two-thirds of the stomach. In his opinion it was a peculiar point about gastroenterostomy when done with the McGraw ligature that the patients showed practically no shock, which might be supposed to be due to the fact that it was possible to do the operation with great rapidity, but he believed the shock in most cases to be due to manipulation.

Dr. WILLIAM J. MAYO of Rochester believed that the Murphy button was of great service in certain cases. He preferred the posterior operation to the anterior one, as in the posterior operation the mucous membrane was better able to protect itself. He admitted that all he knew about gastrointestinal surgery he had learned from the Murphy button, and regretted very much having partially to give up its use. He looked upon Ochsner's method as a correct one, which in his opinion was a strong point in his favor. He referred to Dr. Rodman's operation as being the ideal one, but one that could not be carried out in all cases. Personally he had performed it seven times with recovery in every case.

Dr. JOHN B. MURPHY of Chicago agreed with D. Weir as to the drawbacks to the button, and commented on the quality of the material used by many people in its manufacture. He laid great stress upon the bad results following excessive manipulation and dwelt on the advantages of the posterior operation. Dr. Rodman's paper impressed him very favorably, largely because it avoided any secondary opening. He did not believe, however, that the ideal operation for these conditions had yet been found, and expressed the hope that some one would soon discover it.

Dr. ROBERT H. M. DAWBARN of New York, in referring to Dr. Weir's objection to the use of the special forceps advised by Dr. Murphy, explained a method by which he was enabled to make two corks answer every purpose and obviate the necessity of the use of the forceps.

Dr. L. L. MCARTHUR of Chicago, in commenting on the work of Dr. Maury, spoke of having been working it on the same line himself, and reported that most of his attempts had resulted in failure. He exhibited some specimens illustrating his method, although unsuccessful.

Dr. A. PALMER DUDLEY of New York City referred to a case of cancer of the uterus, in which he attempted to do a hysterectomy, in which the small intestine was so friable that it broke into two pieces during the breaking up of adhesions. He inserted a Murphy button and after waiting nineteen days he became somewhat anxious about it. The patient developed a fecal fistula, and an examination of this lesion demonstrated the presence of the button, so that he felt he held the record for removing a Murphy button through the same incision in which it had been inserted.

Dr. FLOYD W. MCRAE of Atlanta spoke favorably of the McGraw ligature, and argued that the use of rubber was just as good as twine and was more readily sterilized. Another advantage of rubbing over twine was that it began its action quicker, so that the feeding of the patient could be begun earlier. He claimed that one great advantage in the use of the McGraw ligature was the adding

of the McClain needle, all tearing and pulling being entirely obviated. He gave the details of the case operated upon some years ago in which he did a gastroenterostomy and found the abdomen filled with adhesions. Two years later he was obliged to open the abdomen again for intestinal obstruction, which seemed to be high up, and he suspected that the McGraw operation had been a failure which would necessitate making a new opening in the stomach. Upon opening the abdomen he found that the original anastomosis admitted two fingers of his hand readily.

Dr. Maury, in closing, gave the details of some experiments with the elastic ligature on six dogs, which were killed at the end of thirty-six hours after having developed symtoms of tetany. Although Ochsner's case showed a total obliteration of the opening, tetany apparently resulted. In referring to Dr. Lloyd's comments as to the time of cutting through of the twine, which he claimed was about three and a half days, he said it was very evident that the cutting process began some time prior to that. He felt that twine could be as readily sterilized as elastic, and in addition it was more easy to get and did not deteriorate with age.

Dr. WEIR, in closing, stated that he had called attention to all the drawbacks he had observed to the Murphy button, some of which had been made by the instrument-makers, endorsed by Dr. Murphy himself. He alluded to Dr. Rodman's suggestion as being a scientific one and worthy to be considered. As to Dr. Mayo's inference that the procedure was one to be used when a gastroenterostomy or some other procedure had failed, he stated that he used it in conditions which only occur in about 6 per cent. of all cases.

Dr. Rodman closed the discussion by stating that he did not advise his operation in simple cases but only in those in which it seemed probable that a gastroenterostomy would not prove successful, as, for example, when there were multiple ulcers, some of which were probably on the point of ulceration. He called attention to the fact that it was not always possible at the time of operation to state whether or not an ulcer was benign or malignant, but he thought it was fair to assume that there was at least a fair probability of the presence of malignancy in men about fifty. As to the mortality, he did not feel that it ought to be greater than 10 or 15 per cent., but he admitted it would probably always be followed by a somewhat heavier mortality than gastroenterostomy, which is about 5 or 6 per cent. It seemed to him that the operation surely had a place in surgery.

Rupture of Mesenteric Glands During Typhoid Fever Simulating Intestinal Perforation, Report of a Case with Operation and Recovery.—Dr. G. LECONTE of Philadelphia, Pa., called attention to the fact that the profession had long recognized that among the various lesions which may have produced a peritonitis in the course of typhoid fever—rupture of the mesenteric glands was one. It was judged that this occurrence was rare, as no references were made in text books to such a case, and a search through the recent literature revealed but one recorded case. He described the anatomy of the mesenteric glands and their situation, and particular attention was called to the ileocolic group as the regional glands of the lower segment of the ileum, and therefore the ones most likely to be enlarged in the course of typhoid fever. In discussing the pathology of the glandular enlargement it was shown that this was due to an active proliferation of the endothelial cells lining the lymph sinuses, that the coats of the smaller blood-vessels were invaded by these cells, producing thrombosis and minute necroses of the gland; such necrosis almost invariably ends in resolution, even if the typhoid bacillus was present in the gland in large numbers and pure culture. At the Pennsylvania Hospital the post-mortem examinations showed that in many cases the glands of the ileocolic group were enlarged to the size of walnuts, and usually presented microscopic necroses, and yet in none of these cases had the capsule shown any sign or tendency toward breaking down. It was therefore concluded that some other factor must have been present for perforation of the gland in addition to thrombosis of the minute vessels and the presence of the typhoid bacillus; it was suggested that this factor may have been an extension of the inflammation outside of the gland producing a thrombosis of the large vessels, and in this way a necrosis of the capsule of the gland; or, that staphylococcus or streptococci, gaining entrance through the eroded mucous membrane of the bowel, obtained a firm foothold in the gland liquefying its tissue, with ultimate perforation of the capsule. A case was then reported of a Hungarian aged 22, in which the mesenteric glands ruptured on the estimated 35th day of the disease, with the production of a local peritonitis. Operation was performed, the broken-down gland curetted, its cavity packed with gauze, and this area of the mesentery walled off from the general peritoneal cavity by gauze. An uneventful recovery followed. Abstracts of two cases of a similar character were briefly recorded, both of which were operated upon, with death ensuing.

In conclusion it was stated—first, that swelling of the mesenteric glands was a constant lesion of typhoid fever; second, that such enlargement was due principally to a proliferation of the endothelial cells lining the lymph sinuses; third, that these cells, by penetrating the walls of the capillaries and smaller veins, produced thrombosis, with resulting minute necroses; fourth, that such necrosis ended in resolution; fifth, that perforation of the capsule of the gland was dependent upon some causes other than the presence of the typhoid bacillus and thrombosis of the smaller vessels; sixth, that perforation was probably due either to the pressure of the staphylo- or streptococus in the gland, or to the thrombosis of the larger vessels outside of the gland.

Dr. L. J. HAMMOND of Philadelphia said that there were so few recorded cases that it was difficult to add very much to what the author had said, but from the five cases in literature sufficiently analogous to Dr. LeConte's it was possible to at least draw some conclusion as to the mode of invasion of the infection. In two of the reported cases there were sufficient extensive complications to overshadow completely the intestines as the probable focus of infection, and besides the intestinal ulcers found on autopsy were not sufficiently extensive to justify the probability of in asion from this source. He referred to 29 cases in which a slight perforation of the peritoneal coat had taken place in into the peritoneal cavity and the glands themselves were distended with pus so thoroughly that it was natural to assume the condition would have been free in the cavity. In most of the cases the presence of a lump was not noticeable earlier than the thirtieth day, and in one case it did not appear until four and a half months. In all probability Mallory's theory would be found to be the correct one, which was that the infection took place from endothelial cell proliferation.

Dr. L. L. MCARTHUR of Chicago reported one case similar to that of the author in which there were some symptoms of localized peritonitis during an attack of typhoid fever.

Dr. D. N. EISENDRATH of Chicago reported a case of typhoid fever operated upon by Dr. E. W. Andrews of Chicago in which absolutely nothing was found. In thirty hours the patient was dead, and while autopsy proved the existence of typhoid fever and failed to show any perforation it was found that a large mesenteric gland had ruptured similar to that reported by Dr. LeConte. In addition to the localized peritonitis from this cause there was present an enormously dilated stomach.

Dr. THOMAS of Scranton reported a case of typhoid fever which in the sixth week developed a pain on the left side. Examination showed some thickening, and under cocaine 6 oz. of pus were evacuated. In a few days pain de-

veloped on the opposite side, from which 8 oz. of pus was evacuated and the patient made a good recovery.

Excision of part of the ilium and all of the cæcum and ascending colon; ilium and transverse colon united by new method.

Dr. J. Shelton Horsley of Richmond, Va., alluded to the many ingenious methods in use for the uniting of the divided ends of the intestinal tract, and said it seemed to him that the trend of surgical opinion was in the direction of suture rather than mechanical appliances, which was due to the fact that an operative procedure requiring for its performance a special apparatus was thereby handicapped. He referred to a paper already published in which he gave the results of experimental work in intestinal suturing, the result being the method he now employs, which he believed simplified the technical difficulties and obviated stricture in many cases. He detailed his method at considerable length and freely illustrated the various points. He also reported in full a case in which his method had been employed but death resulted four days after the operation. He described at length the results of the post-mortem examination and also the details of the microscopical examination of the specimen, from which the diagnosis was made of syphilitic gumma of the intestines.

Dr. Oliver C. Smith of Hartford urged that there should be more reporting of unsuccessful cases, owing to there being much to be learned from such reports. He expressed the fear that too many men had an idea they were able to operate for appendicitis just as everybody used to think they were proficient in obstetrics, the result being that every now and again a novice runs up against a carcinoma or an intussusception and does not know what to do. An important question which often has to be decided is: should a mechanical device be employed which is to be removed or should one be used which is to be allowed to stay, and he did not believe every man who thought he could operate for appendicitis was competent to make this choice.

Dr. A. J. Ochsner of Chicago referred to the rarity with which surgeons had an opportunity of excising the cæcum, ascending colon and ileum, which he believed was the reason why the subject had never been thoroughly discussed before the section. He urged the necessity of avoiding unnecessary manipulation, and commented on the fact of the great mortality in cases where much manipulation was necessary. He described in detail how he believed the operation referred to in the paper should be done, and alluded to the question of large and small intestine, which terms he said should have been dropped years ago, as no surgeon of to-day would meddle with them owing to it being unnecessary. He advised the use of the Murphy button in such cases as that reported with the use of a few stitches. He reminded the members of the section of the great care needed to see that serous surface was brought opposite to serous surface and peritoneum opposite to peritoneum, so that the operation, if properly performed, would not take more than thirty minutes.

Dr. F. Gregory Connell of Colorado expressed himself as very glad that Dr. Horsley used the through and through intestinal suture, and stated that the one great element to be remembered was the necessity of securing it. He referred to the teaching in years gone by that the suture must not cut through the submucosa, and admitted that a few years ago Dr. Horsley's method would have been looked upon as dangerous. He considered the point of infection a more or less theoretical one.

Dr. Horseley, in closing, commented on Dr. Ochsner's reference to the necessity of avoiding any unnecessary manipulation, and explained why it became necessary to manipulate so much in this case and why the operation took two hours to perform. He claimed he could have done the operation under ordinary circumstances in eight minutes, and drew attention to the fact that if the colon were closed there was but one wound, whereas if the Murphy button were used there would be two. He closed by recommending a direct suture with an ordinary needle and thread, as he believed it to be the method of choice, and was something that was always at hand.

A Case of Retroperitoneal Fibro-lipoma.—Dr. George Ben Johnston of Richmond, Va., reported this case very fully, and reviewed the literature on the subject at great length. He regretted that these growths were so confused and were regarded in the same category with retroperitoneal sarcoma, as so few of the cases in literature have shown any tendency to undergo sarcomatous degeneration. In speaking of the etiology, he admitted but little was kown except that the condition was about 30 per cent. more common in women than in men, and that the large majority occurred between the ages of thirty and sixty. As to the symptoms, he noted that their absence was particularly striking, and thought it remarkable such an enormous growth could take place in the immediate neighborhood of so many important organs and yet remain unnoticed by the patient. The first symptoms are usually those of a dragging sensation, but not often amounting to actual pain, while later, pressure and gastric symptoms become more marked. He alluded to the rarity with which diagnosis has been made previous to operation or autopsy, the most common mistake having been the diagnosing of a cyst owing to the semi-fluctuating sensation imparted by the fat. To avoid this mistake he advised a puncture, as in his opinion a dry puncture into any fluctuating tumor always suggested the former. He went into some detail in reference to the differential diagnosis, and took up a number of conditions with which such cases might be confounded. As to the question of treatment, he believed it to be necessarily operative, which, however, was at the same time very dangerous by the time assistance has been sought or interference consented to. In his opinion the three possible dangers were (1) destroying the blood supply to the overlying length of intestine crossing the tumor with resulting gangrene; (2) shock when operating for the necessary length of time in the exposed abdomen, and (3) tearing the vena cava in separating it from the growth. He quoted Adami's method of avoiding the first danger and the best way of overcoming the others. The operation he employed was described in detail, and a list was given of the men who have successfully operated in these cases. The paper concluded by giving a very full history of the patient with the pathological condition of the tumor and a lengthy bibliography.

Dr. J. E. Allaben of Illinois asked why the tumor could not have been treated in the same way as any simple cyst of the ovary when there were numerous adhesions, *i.e.* simply opened and drained with counter-drainage from the vagina. He reported having done this in a case of his own with good results.

Dr. Johnston, in replying to Dr. Allaben, said the tumor being a solid one it was not possible to open and drain it.

A brief discussion of certain questions regarding the surgery of the biliary tract, more especially the indications for operation and the importance of drainage, followed.

Dr. Maurice H. Richardson of Boston especially emphasized the following four points in this paper:

1. The prevention of hernia, which he said was best accomplished by making a muscle-splitting incision in the right upper quadrant, avoiding the complete section of the motor terminals of the intercostal nerves. This incision sufficed for the majority of cases and for all easy operations, but the muscles in deep dissections of great extent might have to be cut.

2. Permanent biliary fistula always meant unrelieved obstruction to the common duct either from an undiscovered stone or the contraction of an inflammatory condition about the duct.

3. The indications for operation to-day included the known existence of gallstone as demonstrated at abdominal operations for other lesions, provided that the patient's general and local condition were favorable. The removal of gallstones under those circumstances might be accomplished immediately if the original abdominal operation is not a serious one, but it should not otherwise be performed until convalescence had been fully established.

4. Drainage was essential for a complete cure, especially when infections were present either in the gall-bladder or in the biliary passages. This drainage should be full, free, and persistent, and bile should be allowed to flow through the wound until the flow ceases spontaneously. The doctor's personal experience had convinced him that immediate closure of the gall-bladder and of the biliary passages might be attended by complications of a grave nature. Secondary operation for drainage after removal of the gall-bladder was, in his opinion, one of great difficulty and danger.

Gallstones in the Common Duct.—Dr. ARCHIBALD MACLAREN of St. Paul, Minn., believed that gallstones were first formed in the gall-bladder and were usually associated with recurring attacks of cholecystitis, usually of a subacute character. He believed that after the formation of stones in the gall-bladder they might, under favorable condition, remain for long periods of time without causing any characteristic symptoms, the so-called slumbering gallstones. He urged great care in the removal of stones lest some should be left behind, and mentioned a case of his own in which after the removal of fifteen stones the patient died on the fifth day and post-mortem examination showed several stones impacted low down in the common duct. He commented on the many analogies between the appendix and the gall-bladder, and referred to the great uncertainty in the minds of many men as to when gallstones should be removed from the gall-bladder. He advised that they should be removed as soon as a diagnosis could be made with certainty. He gave as the complications produced by a stone in the common duct, first, jaundice; second, cholangitis; third, peritonitis; fourth, inflammation to the pancreas, and fifth, cancer, and then took up the question of the treatment of the opening after removing a stone from the common duct, which he said should usually be done by draining the duct. He reported having operated on fifteen gallstone cases within the past seven months, fourteen of which recovered, and one died.

Dr. J. D. BRYANT of New York spoke in favor of full and complete drainage, and alluded to the fact that the duodenum and the gall-bladder were very common points of entrance of infection.

Dr. C. O. THIENHAUS of Minneapolis gave a blackboard demonstration of his method of operating in these cases.

Dr. J. E. MOORE of Minneapolis stated that he had recently learned three important points in connection with this subject, the first of which was the advisability of early operation, second the importance of thorough drainage, and third, how unwise it was to give up a patient as long as there was life.

Dr. ERNEST LAPLACE of Philadelphia referred to the work of Professor Kehr on this subject, agreed with the author on the question of drainage, and urged in addition to the drainage tubes the use of a large amount of gauze around the tube.

Dr. W. J. MAYO of Rochester agreed with the author as to the advisability of early operation and the necessity for drainage in most cases.

Dr. J. C. BLOODGOOD of Baltimore gave some details of the work done along this line by Dr. Halsted of Baltimore, and agreed in the assertion that secondary operation should, if possible, be avoided by making sure to remove all the stones at once.

Dr. Richardson, in closing, stated that he was still uncertain in his own mind as to whether the gall-bladder should be removed in all cases or simply drained, as he knew that when the gall-bladder was removed some trouble always resulted, although he was not sure just what is was.

Dr. MacLaren, in closing, gave a blackboard demonstration of a part of his operative procedure.

Appendicitis in Children.—Dr. A. J. MCCOSH stated there was still much to learn in reference to appendicitis, and great ignorance as to its etiology; its symptoms were often puzzling, hence the most universal advice to operate in the early stages of the attack. It was often dangerous to wait for the quiescent stage, but it was desirable. Dr. McCosh believed it wisest to operate at once if inflammation could be confined to the appendix. If infection had spread beyond, delay of some hours, or even days, was often beneficial, which was the drift of present surgical opinion. Dr. McCosh stated Dr. Ochsner's plan of treatment had saved many lives, and he believed in it if not followed blindly. He stated that the frequency of appendicitis in children was not always properly appreciated by the general practitioner; after removal surgeons often found appendices show signs of old inflammation, corresponding with the so-called "bilious attacks" of infancy or childhood. In children, symptoms were apt to be masked, pain was not often localized, neither was tenderness. Muscular rigidity was apt to be present, or not appreciable on account of the restlessness and fright of the child. Probably the most important in children was vomiting, or at least the symptom most manifest. It was difficult to differentiate appendicitis in children at times from acute indigestion or the early stages of gastroenteritis, and was often very difficult to differentiate from diaphragmatic pleurisy. In children the progress of the disease was marked often by its insidiousness. Apparently a mild case would drift almost without signs into a desperate one with a general peritonitis; in children there seemed to be less tendency for the inflammation to become localized. For these reasons he advised immediate operation in children at any stage of the disease. He gave age statistics of 1,000 cases in which he had operated; between the ages of 20 and 35, the proportion was over 50 per cent.; before 20 it was 26½ per cent.; before 15 it was 15 per cent.; before 10 it was .068 per cent.; the youngest patients were 12 and 12½ months; the oldest were 72½ years. In 1,500 cases which he had personally examined, he gave the age at which the first symptom of appendicitis manifested itself; the proportion in the first five years of life was 7½ per cent.; in the first 15 years it was 31 per cent.

The Diagnosis of Appendicitis. Should the Appendix be Removed When the Abdomen Is Opened for Other Causes?—Dr. FLOYD W. MCRAE of Atlanta, Ga., stated that the diagnosis of appendicitis was not always easy, and must in a limited number of cases be made by exclusion and careful marshaling of symptoms and physical signs. He advised thorough examination, the avoidance of routine and snap diagnosis, and to have a summary of the most important diagnostic points. He believed that the appendix should be removed when the abdomen is opened and the organ is accessible unless there be some special contraindications, as the non-removal of the appendix is such a frequent cause of incomplete cures following abdominal and pelvic operations. He claimed that disease of the appendix was often associated with floating kidney, gall-bladder, and rectal troubles, advised removal under such conditions when practicable, and gave illustrated cases.

Factors in the Mortality of Appendicitis.—Dr. JOHN B. DEAVER of Philadelphia spoke of the influence of a previous attack of appendicitis on the severity of subsequent attacks and the limited value of adhesions as barriers to the spread of infection. He commented on the collections of pus in the pelvis, right iliac fossa and upward, which gave rise to various states of toxæmia, retrocæcal abscess, retroperitoneal, lymph adenitis, pylephlebitis,

liver abscess, etc., and especially on secondary operations for hernia or fecal fistula.

Dr. ERNEST LAPLACE of Philadelpha agreed with Dr. Deaver as to the removal of the appendix in all cases.

Dr. J. E. SOMMERS, Jr., took exception to Dr. Deaver's advice and was inclined to favor Dr. Ochsner's starvation method in many cases.

Dr. F. L. HUPP of West Virginia related a case which showed several factors playing a part in the mortality of this disease as it did in this case.

Dr. A. JACOBI of New York spoke on the question of appendicitis in children, and after relating the details of a recent fatal case which came under his observation, he spoke at some length on the importance and difficulty of diagnosing the disease, especially in children.

Dr. H. L. MARCY of Boston agreed with Dr. Deaver and said he did so after eighteen years' experience.

Dr. WM. H. WATHEN of Louisville spoke on the relation of gynecology to surgery and particularly in reference to appendicitis, at the same time taking exception to the free flushing advocated by Dr. Laplace.

Dr. A. J. OCHSNER detailed at some length his starvation method of treating appendicitis and gave some illustrative cases with statistics.

Dr. JOHN B. MURPHY of Chicago stated that his experience with appendicitis had been somewhat different from either Dr. Deaver's or Dr. Ochsner's.

Drs. JOS. PRICE and MORDECAI PRICE of Philadelphia agreed with Dr. Deaver as to the necessity of immediate operation in all cases when seen early.

Dr. ROBERT T. MORRIS of New York doubted the advisability of at all times removing the appendix when the abdomen was open for some other cause.

Dr. Deaver closed the discussion by reiterating the advisability of at all times removing the appendix immediately upon making a diagnosis in every case when seen early.

SECTION ON DISEASES OF CHILDREN.

Second Day—Wednesday, June 8.

How to Produce the Best Milk for Artificial Infant Feeding.—Dr. EDWARD F. BRUSH of Mt. Vernon, N. Y., read a paper with this title. He stated that the bovine race was undoubtedly prone to tuberculosis and other forms of chronic disease, and the better the breed from the dairyman's point of view, the more numerously were they afflicted with chronic diseases. Therefore, the first and most important consideration in reforming the methods of supplying milk for infant food should begin with breeding. The cow supplying milk for infant food should be bred from rugged animals, not closely related; she should be quite in disposition, perfectly sound in health, and comparatively well nourished; that is, not excessively fat, nor emaciated. The cow, Dr. Brush said, was man's forager and nurse, and if he attended to her properly, she was the best of his food producers, but she would surely furnish poison for him as easily as good food if he himself did not understand how to prevent her from doing so. The reader was of the opinion that the wealthy amateur dairyman did as much harm, if not more, than the careless, poor owner of dairy cows. Dirt that was not pathogenic was far less injurious than milk from perturbed or nervous cows. The periodical injection of tuberculin must be disturbing. The effort to maintain a herd of aristocratic, highly bred Jerseys might do well for a butter herd, but they were dangerous for the purpose of supplying milk to feed babies. Good cow's milk would nourish an infant without the intervention of the chemist, while bad milk would kill in spite of the man who knew how to modify milk according to the most approved methods.

The Initial Contamination of Dairy Milk.—Dr. RICHARD COLE NEWTON of Montclair, N. J., read a paper on this subject, in which he said that the spread of interest and knowledge among the laity concerning dairy methods was an encouraging sign of the times, and was part of the gradually growing interest in all matters pertaining to hygienic living. The following were the essential points to be observed in the production of good market milk. (*a*) A healthy and well-cared for herd of cows; (*b*) Prevention, so far as possible, of the initial contamination of the milk during the act of milking; (*c*) To minimize, as far as possible, the agitation of the milk, and undue exposure to the atmosphere; (*d*) The cooling of the milk to 40 F. and sealing in it sterilized bottles; (*e*) The maintenance of the milk at 40 F. until it was used as food. Of these postulates, the prevention of the initial contamination was at present the most difficult of accomplishment. The best and most simple method thus far known was that suggested by Professor Conn, which consisted of a pail with a cover, and with gauze or cheese-cloth stretched over a small opening in the cover. By its use, Conn and his colleagues at the Storr's Experimental Station were able to exclude 66 per cent. of the initial contamination of milk by dirt, with very great improvement in the character and keeping qualities of the milk.

Dr. J. P. CROZIER GRIFFITH of Philadelphia said that while sterilization and Pasteurization of milk were necessary under certain conditions in order to kill the germs, they did not destroy the toxins. What we wanted was pure milk, and the papers of Drs. Brush and Newton were in accord with the modern scientific study of this subject.

Dr. F. L. SMITH of Bridgeport, Conn., called attention to the fact that the milk of cows was readily affected by the food they ate. Jersey cows were especially susceptible in that respect. He recalled an instance in which the milk became unfit to drink because the cows had been fed on oat straw containing a little wild mustard. Turnips and turnip-tips would also impart a strong taste to the milk.

Dr. L. C. AGER of Brooklyn, N. Y., who was connected with the Milk Commission in that city, said they were trying to eliminate one possible source of contamination in the handling of the milk by having it bottled at the farm instead of at the creamery.

Dr. W. B. ULRICH of Chester, Pa., said that if the profession paid as much attention to the quantity of feeding as they did to the quality infants would be better off. The fact seemed to be lost sight of that the purest milk or food would make a child sick if it received too much of it. He thought there was much more harm done by overfeeding than by under-feeding.

Chronic Constipation in the Infant.—Dr. J. ROSS SNYDER of Birmingham, Ala., read this paper. He said that complete digestion embraced a three-fold function, namely, conversion, absorption, and evacuation. There was a conversion and absorption of the nutrient elements of food, and following this, an evacuation of the refuse. The successful performance of these several divisions of the digestive function was dependent on each other, the character of the food ingested, and on certain secretions and motions of the organs involved. In the treatment of this condition, no routine method could be followed. The first thing was to find the cause, and that, when found, would suggest its own correction. If the condition was neglected while the child was still a young infant, the treatment became an altogether different and more difficult question. If the constipation was not of very long standing, atony of the bowel might be overcome, after correcting the diet, by an endeavor to establish habit. Soap and glycerin suppositories were to be avoided in the young, if possible, and massage should never be practised in those cases. A knowledge of the relationship between the fæces and the injesta should be obtained, and any abnormality in the first pointed to some abnormality in the latter. General regulations on this subject, such as were found in some textbooks, suggesting the use of cream, oatmeal, etc., were misleading and only showed how carelessly the subject had been handled by otherwise careful writers.

The Effect on the Nervous System of Children of Uncorrected Refractive Errors and Muscular Imbalance.—By Dr. J. H. CLAIBORNE of New York City. The author's con-

clusions were as follows: (1) Nervous symptoms of a variety of kinds occurred as the result of eye-strain. (2) Eye-strain was due to refraction errors, the imbalance of the external ocular muscular system, or, more frequently to a combination of the two. (3) Of these two, the refractive errors were by far the more frequent cause. (4) Muscular imbalance alone might cause it. (5) Headache was by far the most common nervous symptom in children caused by eye-strain. (6) The headache was chronic, or induced directly by near work, and was generally in the forehead or temples. (7) Migraine or hemicrania due to eye-strain was comparatively rare in children. (8) Any nervous symptom in children should arouse the suspicion of ocular defects, either as a direct or a contributing cause. (9) The refractive correction should be made under atropine. (10) Muscular defects were secondary to the refractive, and should be corrected only in certain cases.

Congenital Occlusion of the Lacrymal Canal, and Acute Contagious Inflammation of the Conjunctiva Occurring in Children.—Dr. JOHN E. WEEKS of New York City read a paper on this subject, in which he discussed in a general manner the acute contagious inflammations of the conjunctiva, as seen in children, and also referred briefly to congenital occlusion of the lacrymal canal. The latter condition was often mistaken for acute contagious conjunctivitis, and it required careful observation to avoid confounding the two. Treatment, if at all irritating, rather tended to increase the difficulty than to cause it to subside. The treatment should consist simply in cleansing the conjunctival sac with a solution of boracic acid two or three times daily, and in protecting the skin of the lids by the use of some bland ointment. No attempt should be made to open the lacrymal canal by the passage of probes or in any other way until nature had been given a fair opportunity to establish the passage. The patency of the passage would become established in from two to six weeks in a large percentage of the cases. If after the lapse of two months the passage was not free, a canaliculus might be slit up sufficiently to permit the passage of a small lacrymal probe, and a probe passed through the obstruction. Dr. Weeks said that the acute contagious ophthmalmias to which children were subject were those that developed as a consequence of infection from the pneumococcus, the Koch-Weeks bacillus, the gonococcus, and the Klebs-Loeffler bacillus. The clinical picture as a result of infection from the first two microorganisms mentioned was that of a mucopurulent conjunctivitis. A pneumococcus conjunctivitis was indistinguishable, clinically, from a Koch-Weeks bacillus conjunctivitis. Acute mucopurulent conjunctivitis due to the pneumococcus or to the small bacillus was devoid of danger to vision, excepting in an extremely small percentage of cases, while gonorrhœa and diphtheria might cause great damage to vision in a large percentage of cases. For this reason, the true diagnosis was important, and if any uncertainty existed regarding it, a microscopical examination of the secretion should be made. The remainder of Dr. Weeks' paper was devoted to a discussion of the treatment of these various types of conjunctival inflammation.

Enuresis.—Drs. MAURICE OSTHEIMER and I. VALENTINE LEVI of Philadelphia presented this paper which embraced ninety cases of enuresis in children observed in dispensary and private practice. While there was no one cause of the affection, reduced tone of the vesical sphincter muscle was present in most cases. This was often the result of some antecedent or simultaneous illness. Among the many methods of treatment, the writers found that in the vast majority of cases recovery followed the use of the tincture of belladonna in ascending doses, in the mild cases; and atropine and strychnine in the intractable cases. The latter treatment, begun with atropine, gr. 1-240th, and strychnine, gr. 1-480th to one drop of water, was gradually increased until the incontinence ceased. The highest dose was continued from two to four weeks, and then gradually decreased, so that the entire treatment usually covered from six weeks to three or four months. Fluids were stopped after supper, and errors in diet were corrected in all cases.

The Bacteriology of Summer Diarrhœa.—Dr. WILLIAM H. PARK of New York stated that the intestines were the only organs of the body which contained large amounts of fermenting and decomposing material. The bacteria contained in the intestinal tract numbered many billions. These bacteria were constantly engaged in fermentative and putrefactive processes, which exerted a very important influence on the organism of the body. The intestines of the new-born were usually free from bacteria, but within a few hours after birth they gained access through the mouth and anus. Within a few weeks, bacilli of the colon group were always present, and usually, varieties of streptococci and staphylococci, as well as hay bacilli and allied groups. The intestinal evacuations of the child contained a daily average of fully one billion bacteria. Certain difficulties were encountered in the study of intestinal bacteria. Except for the lower part of the rectum, we could not directly reach the mucous membrane during life. Furthermore, there was a striking similarity between the bacilli present in the normal intestine and those varieties believed to be pathogenic. The difficulty was still further intensified by the probability that bacteria existing usually in the intestine as harmless refuse fermenters, may, under changed conditions, excite disease.

A Summer's Experience with Infantile Dysentery.—Dr. J. H. MASON KNOX, Jr., of Baltimore, Md., stated that during the summers of 1902-3 epidemics of diarrhœal disorders among infants and young children appeared in Baltimore. A large proportion of these cases, properly investigated, were found to be produced by the proliferation in the intestinal tract of the *bacillus dysenteriæ* (Shiga). The histories of these cases, and the clinical manifestations of the disease were similar to those observed in previous epidemics in Baltimore and other American cities, and there was good reason for the belief that the *bacillus dysenteriæ* was an important factor in this great scourge among children. The disease began in June, reached its height in July and gradually declined in August, although sporadic cases occurred throughout the year. The number of cases appeared to be directly increased by excessively hot weather. Children under one year were most susceptible; those over three years were rarely attacked. Nearly all cases occurred among infants artificially fed. Ill-nourished children, particularly those fed on condensed milk, were less able to withstand the dysenteric infection, and formed a large proportion of the fatal cases. The cases could be readily divided into two groups: Those in which the symptoms of toxæmia were most prominent, and those in which there was evidence of a destructive lesion of the bowel. Mucus was noticed in the stools in all cases. Blood was present in the discharges in moderate amount in 42 per cent. of the cases. The keynote of the treatment was promptness. If the food could be stopped, and the alimentary tract emptied within a few hours after the onset of the symptoms, most infections could be aborted. The results of the anti-dysenteric serum treatment were disappointing. Its use was perfectly harmless under aseptic precautions.

The Bacillus Dysenteriæ in Relation to the Diarrhœal Diseases of Infants. A Clinical Study of 237 Cases.—Dr. L. EMMETT HOLT of New York gave the result of the use of anti-dysenteric serum in the eighty-three cases of intestinal infection by the *bacillus dysenteriæ* (Shiga) that had been studied in connection with the Rockefeller Institute in various hospitals in New York, Boston, Philadelphia, and Baltimore. Thirty-eight of these eighty-three cases ended fatally. On the whole, the result of the serum treatment was disappointing. No unfavorable

symptoms followed its use in any case. In a few instances, an eruption, usually urticaria, followed the injections. That decided improvement appeared to follow its use in only twelve cases was not very encouraging, but several factors worked against its success. In a large proportion of the cases it was used late in the disease. Again, it was, as a rule, only used in the most severe cases; and finally at the beginning of the season, no rules had been formulated as to the size and frequency of the dose. Hence it was evident that many of the doses were too small. Four patients were moribund at the time the serum was given. Of the eighty-three cases, sixty-seven were hospital patients. The serum should be used early, before serious lesions had developed, or before the patient's general nutrition had been too profoundly impaired. The latter referred particularly to young infants. The injections should be repeated, one or two doses being given daily in severe cases.

Some Findings in Summer Diarrhœas of Children.—Dr. JOHN C. COOK of Chicago read this paper, in which he reported twenty-nine cases of diarrhœa coming under his observation during July and August, 1903. The cases were reported in order to show the relative frequency of certain bacteria not ordinarily given prominence in this connection. Cultures were simultaneously made from the mouth and fecal discharges, and observed as closely together as possible. Both in the oral secretions and in the fæces pyocyaneus and mycoides were found in a number of the cases.

The Management of Summer Diarrhœa.—Dr. THOMAS S. SOUTHWORTH of New York City read this paper. After calling attention to the prominent etiologic influence of high atmospheric temperature in the production of summer diarrhœa, the author emphasized the importance of prophylaxis, both dietetic and hygienic, and stated that it should be begun before the onset of the hot weather. The danger was chiefly in proportion to artificial feeding. The greatest safety was secured by heating milk, however pure. Errors in diet, as well as bad milk, were the exciting causes, but local conditions and lesions once started were progressive and intensified by milk diet. Toxæmia was the prominent factor. The prompt elimination of the milk from the diet and the evacuation of the bowels vastly reduced the mortality. Opium should be used with great care. True cholera infantum was a rare type.

(To be Continued)

A New Diagnostic Method.—Herman Lawrence speaks of a new clinical method of diagnosis, by "markings" obtainable in different diseases. He believes that the irritability of tissues in general may possibly, in some diseases, be calculated by the irritability of the tissues of the skin; at any rate, that certain markings aid the prognosis in certain diseases, and may forecast a relapse of the disease, and that certain markings explain the exaggeration of the symptoms in some individuals, and that probably suitable treatment may be worked out by observing the effect of treatment upon the markings of the skin. The writer quotes the following case as illustrating his method: The patient was suffering with scleroderma. On marking the skin over the patches there was a white line followed by a white line. Just beyond the patch there was a white line followed by a poor red line, which, later on, became a white line, and upon the healthy skin, the marking was a white line, followed by a red line. It is sometimes necessary to provide a differential diagnosis between scleroderma and leucoderma. By this method it will be found that the marking makes an easy diagnosis; in the case of scleroderma, the marking is 1.5, and in the case of leucoderma 1.2. In this case, after an interval of four weeks, the autograms showed that the disease was growing worse, though by the evidence from sight and touch there was no appreciable alteration in the skin trouble. By comparing the autogram takes ten different times, the progress of the disease can be definitely ascertained.—*Intercolonial Medical Journal of Australasia.*

FOREIGN BODIES IN THE EYE AND THEIR REMOVAL WITH THE ELECTRO-MAGNET.*

BY WILBUR B. MARPLE, M.D.,
NEW YORK.

OPHTHALMIC SURGEON, N. Y. EYE AND EAR INFIRMARY; VISITING OPHTHALMIC SURGEON W. H. AND A. H. HOSPITAL; CONSULTING OPHTHALMIC SURGEON BABIES' HOSPITAL, ETC.

IN presenting this paper to the members of the Clinical Society this evening I shall endeavor to avoid a too technical consideration of the subject, but shall rather aim to give a general idea of a branch of ophthalmology which has many fascinating details for the special student. I shall not treat you either to a dry recital of a lot of histories of cases, but shall present the records of a few which are types of various forms of these injuries.

This paper will only treat of those foreign bodies whose removal is possible with the electro-magnet, viz., pieces of iron or steel. Particles other than of this nature, such as glass or copper, are very much more difficult to remove, but fortunately injuries with such particles do not occur nearly as frequently nor is their prolonged sojourn in the eye nearly as apt to damage it as a visual organ. With regard to such particles (not of iron or steel), as Haab[1] says, it is often more advisable to leave them in the eye, (unless of course they can be seen somewhere in the anterior segment of the globe where they are accessible) than to open up the vitreous and probe around, as it were, in the dark, with forceps and other instruments in search of the foreign body. To endeavor to remove such oftentimes damages the eye more than to leave it undisturbed. It is, therefore, very fortunate that the great majority of bodies penetrating the globe are iron or steel.

The great growth of manufacturing of all kinds all over the world has increased to a corresponding degree the number of cases of injuries of the globe. Praun[2] collated statistics from forty-five leading ophthalmologists and found that injuries of the eye of various kinds constituted 4.89 per cent. of all cases of eye troubles. In factory districts this rose to 12 per cent. Before the introduction of the electro-magnet, and not infrequently even after the introduction of the small hand magnet, the eye was so seriously injured by the attempt to extract the foreign body that it was rendered useless as a visual organ. I remember, not more than ten years ago, hearing a prominent colleague say in a discussion on the removal of such foreign bodies lodged in the posterior half of the eye that according to his experience it would be as well to remove most of such eyes at once. Knapp in 1885[3] said, "When the fragments lie invisible in the vitreous they can be removed with the magnet or not at all. If the attempt fail or injure the eye considerably, enucleation should not be delayed." The introduction of the giant magnet, as well as the great improvement in the technique of its use, has changed all this. So that to-day the success attained in saving the eyes of the large number of victims of these injuries, and that too, oftentimes, with useful vision, is one of the most brilliant achievements of modern ophthalmology.

Hirschberg,[4] in his history of ancient ophthalmology, says that the first reference to the use of the magnet stone in surgery occurs about the beginning of the Christian era, when reference is made to its use in extracting an arrow head. This is probably a fable, however. Fabricius von Hilden (1550-1634), near Cologne, is said to have removed with a magnet, at the suggestion of his wife who was a midwife, a small particle of iron from the superficial layers of the cornea. Meyer of Minden in 1842 removed a foreign body through a wound of the sclera in a similiar manner. Mackeown[5] of Belfast in 1874 used a small bar magnet which he introduced into the vitreous and succeeded in extracting a piece of steel, and again in 1878[6] removed with a permanent magnet pieces of iron from the iris. The first person, apparently, to use an electro-magnet in these cases was McHardy[7], who in 1878 brought a large electro-magnet up to an eye with a piece of steel imbedded in the lens. When the magnet was still two inches from the eye, the foreign body flew into the anterior chamber and was extracted. Hirschberg[8] in 1875 made un unsuccessful attempt to remove a piece of steel from the vitreous (after extracting the opaque lens) with a thin iron tip curved like a branch of an iris forceps and attached to a horseshoe magnet around which the electric wire was coiled, but in 1879[9] he succeeded in a similar case, passing the tip through an incision in the sclerotic. This was the first case in which a foreign body was extracted from the vitreous with the electro-magnet. Knies[10] in 1881 first used a much larger electro-magnet for the removal of a piece of iron imbedded in the iris. He also suggested its use in drawing a foreign body imbedded in the ciliary body or anterior portion of the vitreous into the anterior chamber and thence out. But he did not pursue the subject further, nor did he apparently appreciate that this method would succeed even if the particle was at the back of the vitreous. Haab[11] of Zurich in 1892 first introduced the giant magnet and developed the technique of its use as an aid in diagnosis and then in the removal of the foreign body, and his magnet has been very generally adopted. One objection to it is that on account of its great size and weight the patient usually has to be brought up to the magnet seated in a chair, although occasionally apparatus is constructed which makes it possible to have the patient in the recumbent posture. This is a great advantage, as the patient is under much better control than when seated in front of the instrument. A readily movable magnet equally powerful would be a distinct advance. Johnson of Patterson, N. J., Lippencott of Pittsburg, and Sweet of Philadelphia, among others, have constructed smaller and more portable and yet quite powerful magnets which are very useful. Recently Volkmann[12] of Berlin was led to investigate the theory of the magnet and has con-

*Read before the New York Clinical Society.

structed one which he claims is made on correct principles. While it is very much lighter and more easily handled than the Haab magnet, yet it is said to be clinically a much more powerful instrument. When employed recently in Hirschberg's clinic[18] the Volkmann magnet got so hot, including the tip, that one could not touch it, which showed that there was some fault in its construction.

The large magnet is used for two purposes:

First, As a means of diagnosis; second, for the removal of the foreign body.

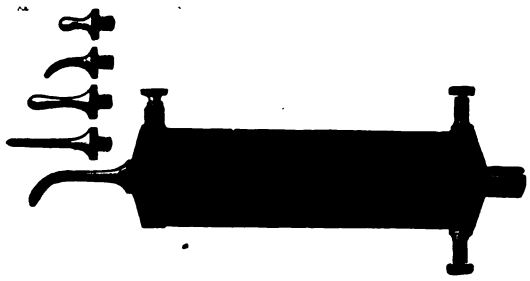

FIG. 1. Small Hirschberg magnet with tips for introduction into the eye

1. *As a means of diagnosis.*—If a patient who has had a recent injury of the eye is brought closer and closer to the giant magnet, the occurrence of pain more or less severe is a positive diagnostic sign of the presence of a piece of iron or steel somewhere in the interior of the eye. It is caused of course by the pulling or drawing toward the magnet of the particle, oftentimes with rough or jagged edges, imbedded in the sensitive structures of the eye. If the particle is of any considerable size, it is astonishing with what force it is drawn toward the magnet. I have seen it bulge the sclera in such a way as to change entirely the shape of the eye at this point, and it may even make the whole eye move. If the wound of entrance, however, is so large as to indicate a foreign body of considerable size, great caution should be taken. The force of the magnet can be gradually increased by seating the patient at a distance c. a foot or so and having him slowly approach the magnet, or, if the latter is portable, which is even better, we can push it slowly closer and closer to the eye. Not infrequently the diagnosis by pain can be made at some little distance. As is true of most other useful things, we can do a great deal of harm as well as a great deal of good with the large magnet. Our object should be to make the diagnosis, and if possible to remove the foreign body, but to do this with the minimum amount of injury to the eye. Oftentimes patients appear to be at first afraid of the magnet and shrink from it, but we must not mistake this for pain. A small but strong magnet with telescopic tip is often useful in localizing the pain, and thus the foreign body.

2. *For the removal of the foreign body.*—There are two methods of using the electro-magnet for the removal of particles of iron or steel from the eye. When it first began to be used for this purpose it had a small sound-like tip, which was introduced through an incision into the interior of the eye, and brought as close as possible to the foreign body. With the giant magnet, however, we endeavor to draw the particle, wherever it may be located, into the anterior chamber and thence out. If there is a recent unclosed scleral opening of course we would try to get the foreign body out here. The one method acts at a distance, the other by contact, actual or approximate. In certain cases there is still a difference of opinion as to which is the best method, but when the foreign body is located in the anterior segment of the eye—that is, in the lens, iris or even in the ciliary body—most observers are pretty well agreed as to the best manner of proceeding. The particle is to be drawn into the anterior chamber by some strong magnet, and thence out of the eye through the wound of entrance if recent (enlarged if necessary), or a small incision may be made into the anterior chamber at its periphery and the tip of the small magnet introduced here, and thus the foreign body be extracted. As to the best point at which to make your opening into the anterior chamber, I prefer to do this at the periphery except when the wound of entrance is still open or its edges can be easily separated. The method may be best illustrated by one or two cases.

On May 7, 1903, I saw a patient, W. B., æt. thirty-five, into whose right eye a piece of iron had entered the day before at his home in Schenectady, N. Y. His condition was as follows: There was a slight injection of the globe; pupil dilated one-half (atropine?); fundus clear. Could see nothing of the foreign body in the interior. There was a small wound 2 mm. long in the sclera (1 mm. from corneal margin, in the upper nasal quadrant), anterior chamber shallow. Tension —2; vision, counted fingers at ten feet. It was evident that the foreign body was somewhere in the anterior segment of the eye, as the media were quite clear. *Treatment.*—When the patient was gradually approached to the Haab magnet until the tip was just in contact with the wound of entrance he was conscious of but little

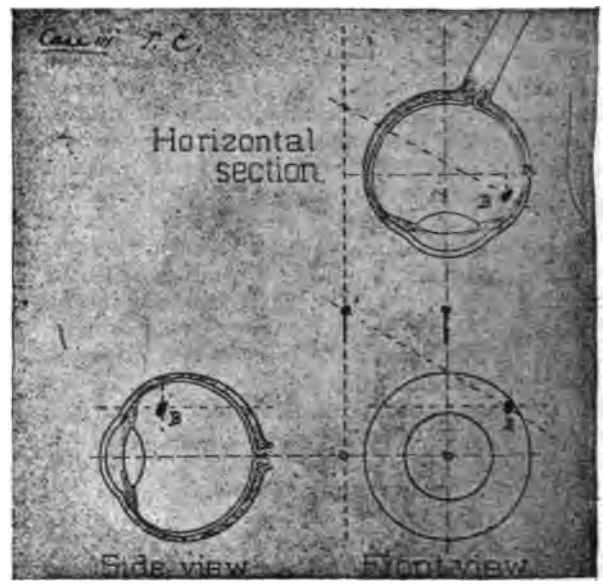

FIG. 2. Localisation of particle in interior of eye by Sweet's method in one of Dr. Risley's cases. Projection in three planes.

if any pain. With the tip still in contact with the globe at the same point, the current was turned on and off several times. By carefully observing the eye all the time, it was seen that the upper nasal margin of the pupil dilated a trifle each time the current was turned on; at the same time a few drops of blood oozed from the iris near the wound of entrance. It was apparent that the particle was lodged in the iris somewhere between the pupillary margin and the upper nasal periphery. The tip of the magnet was then placed to the temporal side of the center of the cornea to see if it would not draw the piece of iron from behind the iris through the pupil into the anterior chamber, but the attempt was not successful. But when the eye was examined now by artificial light the minute particle could be seen entangled in the iris near its root close to the wound of entrance. The anterior chamber was opened here with a Graefe knife, and a small portion of iris with the foreign body ad-

herent drawn out and excised. Patient discharged in a week. A few days ago I received a letter from him saying his eye had given him no trouble since he left the hospital, and he can see apparently as well with his right as with his left eye. The piece of iron, which I show here, was 2mm. long, .05 mm. broad, and 0.1 mm. thick. The advantage of the giant magnet could not be better shown, for the particle was so minute that its presence could scarcely have been detected with a smaller instrument. My colleague, Dr. Callan, recently in a similar case in which the foreign body was lodged in the iris succeeded in drawing the latter out, and after removing the particle of iron replaced the iris in the eye. After the patient was discharged it was impossible to tell that anything had ever been done to the eye. This case of mine illustrates also an observation which I think Dr. Gruening first made, viz., that when there is no prolapse of the iris or ciliary body in these cases the foreign body has probably entered the globe, whereas if there is a prolapse the particle has probably wounded but not remained in the eye. That is, if the particle strikes the eye with sufficient velocity to puncture it completely, the small wound closes so quickly that no prolapse occurs, and *vice versa*. This symptom if positive is an exceedingly valuable one, and since it was brought to my attention by Dr. Gruening, the indication conveyed by it has always been corroborated. In the above case the wound of entrance was 2 mm. long; there was no prolapse of the underlying structures, and a piece of iron was found in the eye. On June 16 I saw a patient whose left eye had been struck as he was chiselling stone. I found a very small prolapse of the iris just at the nasal limbus, forming a little cyst which could be emptied into the anterior chamber by pressure. The length of the corneal wound was only 1½ mm. The accident had happened two weeks previously, the media were clear and there was nothing to be discovered in the interior and scarcely any redness. The prolapse was excised after breaking up the adhesions, and in a few days patient was discharged with eye quite white, and he has had no trouble with it since. Here the wound was only 1½ mm. long; there was a prolapse but no foreign body was found in the eye. This observation is true only of clean straight incised wounds. If, however, the opening is large, or irregular and ragged, a prolapse in all probability will occur, as is shown in some cases reported by Myles Standish.[13]

FIG. 3. Exact size of piece of wire 1 cm. long. One-tenth of this weighs 1 mg., and a piece this size has been frequently removed by the Haab magnet, even when at the back of the globe.

In a recent letter from Professor Haab on this subject he writes: "The size of the wound, it appears to me, largely determines whether the iris prolapses or not. But, according to my experience, the observation of Gruening in the great majority of cases is entirely correct, and is valuable for the differential diagnosis."

If the foreign body is in the lens a similar method is pursued. In one case of mine the little glistening mass of steel could be seen exactly in the center of the lens, the rest of which was transparent. The large magnet drew it into the anterior chamber, in the periphery of which an incision was made, into which the tip of the smaller magnet was introduced and the body removed. A cataract subsequently developed, which was removed, leaving the vision normal. This piece of iron, 8 mm. long, was removed May 19 from a patient by the large magnet. It had passed through the cornea in its lower temporal quadrant and pinned the iris there to the lens, which was opaque. All that could be seen of the spicule was about 1mm.; the rest had buried itself in the lens and vitreous. The opening in the cornea was enlarged a little with a cataract knife, and the tip of the Haab magnet applied to the cornea here, the current turned on, when at once the fragment of steel flew out of the eye and remained sticking to the magnet. The traumatic cataract was subsequently removed, giving the patient good vision.

If the foreign body has entered the eye and the lens is opaque, I agree with Haab that there is no special advantage in attempting to locate it exactly before we attempt to extract it. It is possibly somewhat more surgical to do so, but the result in the end is about the same, for the body has already caused a cataract in passing into the eye. Such a case is illustrated in the following brief history: J. L. was using a cold chisel on the night of April 3, 1903, when a piece of steel flew into his left eye, which showed a very small wound already closed in the upper nasal quadrant of the cornea 1 mm. from the limbus; there is a small puncture in the iris just behind the corneal wound. The lens is opaque; foreign body has disappeared somewhere in the interior of the globe. No attempt was made to localize the fragment of metal, but the patient was seated in front of the giant magnet and felt no pain until several attempts had been made with the tip in contact with the center of the cornea, when suddenly the particle appeared behind the iris, and before the current could be turned off it had torn its way through the lower part of the iris into the anterior chamber, whence it was removed by the tip of the small magnet. Patient made a rapid recovery and cataract is absorbing. In such a case, when we do not know in what part of the eye the foreign body is located, the tip of the magnet should be placed at the middle of the cornea so as to avoid drawing the particle into the ciliary body. If we had localized it by other means we might possibly have avoided wounding the iris a second time, as evidently the fragment had fallen to the lower part of the vitreous. This second puncture of the iris (produced in removing the foreign body) quickly closed up, however, and left no trace. After having gotten a piece of iron into the anterior chamber, as in the above case, or out of the wound of entrance possibly, it is well to apply the magnet again, for not infrequently there is more than one fragment in the eye, and we should not leave any behind.

If we have to deal with a case in which the lens is transparent but the fragment has evidently penetrated into the vitreous chamber, there can be no question but that its removal with the least possible injury to the eye in so doing is facilitated if we can first localize the foreign body. Previous to the discovery of the Röntgen ray the method usually employed to localize a fragment of iron or steel within the eye (unless the media were clear and it could be localized with the ophthalmoscope) was by means of the sideroscope. By this was meant some arrangement of a magnetic needle whose deflections of course would be more considerable the nearer the needle point was brought to the spot in the eye where the foreign body was located. Dr. T. R. Pooley [14] of this city first studied this subject, and he found that localization was more successful if the particle of metal in the eye was previously magnetized by induction by passing a strong permanent magnet close to the eye. Asmus [15] devised an exceedingly sensitive and delicate sideroscope in 1894, but it must be used in a place remote from the influence of strong electric currents, such as are used for electric lights or electric trams, and, as

Knapp says, to handle it requires the patience of a saint. Recently Hirschberg[18] has simplified the Asmus instrument, so that while somewhat less delicate it is more convenient and practicable. If the particle is not very minute (in which case the instrument often fails to indicate it) the localization is decided by passing the needle in various meridians of the eye and finding where the deflection is most marked. But better than the sideroscope for localizing purposes is the Röntgen ray, though here also, if the fragment of iron is exceedingly small, the attempt may fail.

Various methods of exposure have been employed in localizing foreign bodies in the eye, but as good a one as any (if not the best) is that of Dr. Wm. M. Sweet of Philadelphia who "employs two metal indicators, one pointing to the center of the cornea at a short and measured distance from the latter, and the other situated to the temporal side at a known distance from the first." Two exposures are made in order to give different relations of the shadows of the indicators and the foreign body in the eye-ball or orbit. In the one exposure the tube is on the same horizontal plane as that of the two indicators, and in the other exposure the tube is at any distance below this plane. In this way the foreign body has been repeatedly located by Dr. Sweet with beautiful exactness. The following case would have been one in which some such method might have been employed and illustrates, moreover, a class of cases in which there is still some difference of opinion as to the best method of procedure in removing the foreign body:

J. D., æt., forty-two, seen April 27, 1903. While chiselling stone four weeks ago he was struck by a small particle in the left eye, since which time his sight has been bad. When first seen by myself the eye-ball was slightly injected, pupil dilates normally under atropine, the lens is clear, and a red reflex from the fundus can be obtained, but no details can be seen on account of vitreous opacities. Vision in this eye was limited to perception of movements of the hand at a few feet. No wound of entrance could be made out. Now here was a case in which the lens was transparent, yet if the foreign body was in the eye, it was somewhere in the vitreous (or back of it), which was full of opacities. It is just in this class of cases that a rather radically different procedure is advised by different authorities. Haab and those who follow his advice would say, Localize it if necessary in order to take all precautions possible not to injure the lens in extracting the particle of iron. Then draw the foreign body, if any is present, around the periphery of the lens into the anterior chamber and thence out. And on the other hand, Hirschberg, and others hold that in such a case, the better method is to localize the foreign body accurately with the siderosope or, better still, by means of a radiograph, then to make a small incision through the sclerotic and subjacent structures as near as possible to where the particle of iron has been localized and then insert the tip of the small magnet into the wound and thus extract it. Those who prefer to go directly into the vitreous, say that with the other method, the foreign body has to take a longer course in extracting it, may injure the ciliary body or zonula or tear through the lens, causing a traumatic cataract. Dr. Samuel D. Risley[18] reported in 1902 an interesting series of cases in which the foreign body was localized with beautiful exactness by Dr. Sweet and removed from the vitreous successfully, and the results were brilliant. In a letter received from Dr. Risley early in this month, he informed me that there has been no detachment in any of these cases and the accompanying figure (Fig. 2), kindly loaned me by him will show how accurately by Dr. Sweet's method the foreign body is located in the eye. The illustration shows the situation of the particle in three planes. I have recently had another case in which I found (and removed) the piece of iron exactly where Dr. Sweet had previously localized it for me. The criticism made against this method is that in employing it we injure (in making the incision) the choroid and retina, which may be followed by a considerable intraocular hemorrhage. But the injury to the vitreous by the knife making the incision and by the introduction into it possibly of the tip of the magnet is the most objectionable feature of the method, for the more the vitreous is injured the greater is the danger of infection of the eye and also of subsequent detachment of the retina. What Hirschberg[18] says, however, is true, that "we must not forget that many of the cases in which the giant magnet has drawn the foreign body from the vitreous into the anterior chamber have subsequently had a detachment, while a sufficient number of the cases from which he has extracted the foreign body directly from the vitreous by the tip of the small magnet, have been kept under observation for five, ten, and fifteen years, or more, and without any detachment." There is no doubt but that good results have been obtained by both methods, but the question is Which method will give the largest percentage of *permanently* good results? Time and a longer observation of our cases will unable us properly to decide this question.

But to return to our patient, with the foreign body lodged probably somewhere in the vitreous. The eye presented so few symptoms of irritation that I was somewhat in doubt whether there was a foreign body in it or not. The patient was placed in front of the large magnet and brought up slowly to it, until the magnet tip touched the center of his cornea. This was repeated several times without eliciting any pain. He seemed afraid of the instrument, but had no pain. Before discontinuing the experiment I concluded to try again. When the tip of the magnet was almost in contact with the cornea again, I saw a small particle suddenly escape through the pupil into the anterior chamber, just back of the magnet tip, whence it was readily removed, together with a small bit of white stone adherent to the particle of iron. The eye gradually cleared up and the lens remained transparent, showing that the foreign body passed from the vitreous through the zonula fibers without injuring the lens. In this case I did not make any attempt to localize the foreign body either with the sideroscope or the radiograph. Yet the result was apparently as satisfactory as if I had done so. It would seem, however, to be more surgical in such a case with an uninjured lens to endeavor to localize the foreign body before putting the patient in front of the large magnet. It might enable us to approach the magnet tip to the eye in such a direction as to minimize the danger of injuring the lens. But, oftentimes, if the patient is not brought too close to the magnet at first, the foreign body will move slowly through the vitreous (as it has been observed to do) and pass around the curved surface of the periphery of the lens without injuring the latter.

Then we meet with cases in which the foreign body has penetrated through the various anterior structures of the eye and has lodged in the retina, where possibly it may be seen with the ophthalmoscope. Through the courtesy of Dr. Gruening, in whose clinic this case presented itself recently, I am able to demonstrate to you with the Thorner ophthalmoscope a patient of this kind. His vision

is little, if at all, impaired at present, and he came to the clinic to see if there was anything the matter, for he had felt the momentary sting of the particle, but had noticed no impairment of his sight. You can see the sliver of metal imbedded in the retina, and it has been there now for three months. Now what is the safest method to pursue in such a case? Many would advise its removal either with the giant magnet by way of the anterior chamber or through an incision in the sclerotic as near as possible to the foreign body. Situated as this little particle is at the posterior pole of the globe, if we should place the tip of the magnet at the center of the cornea, we would draw it directly into the lens, and a traumatic cataract would result. In such a case the proper way of using the giant magnet would be as Haab suggests, to have the patient look to the extreme right or extreme left and then apply the magnet cautiously near the equator of the eye, and thus draw the particle first into this vicinity, being quick to turn off the current as soon as any expression of pain is elicited, so that the foreign body does not imbed itself deeply in the retina and choroid. Now, with the particle thus transferred to the equatorial region of the eye, if the magnet tip is brought up to the center of the cornea and the current turned on, the piece of iron will be drawn into the anterior chamber to one side of the lens without injuring the latter. Such a method should be employed when the foreign body is lodged in the vicinity of the pole of the eye. Pursuing some such plan, Haab was successful in removing the foreign body in twenty-eight out of thirty-four cases in which the piece of steel was lodged in the retina or adjacent structures.

The objections to removing the foreign body in this case by an incision through the sclera have already been discussed. I overheard one colleague, after examining this patient, say to a friend: "If that was my eye I would leave it alone." And this has been the conservative decision of Dr. Gruening. And this leads us to a consideration of the possibilities in case we do leave it alone. The most favorable thing which may happen is that the little piece of iron will become completely encapsulated. If this takes place it is possible that it may remain in the eye indefinitely without doing any harm. But experience has shown that after perforation of the globe, even under perfectly aseptic conditions, by a piece of iron or steel which does *not* become encapsulated, the prognosis as to sight is generally very unfavorable unless the foreign body is removed. The chemical action of the iron causes such considerable changes in the tissues of the eye that the condition of *siderosis bulbi*, as it is called, or rusting of the eye, is to be regarded as a very dangerous malady of the eye. It was first described at the International Medical Congress at Berlin in 1890 by Bunge[20], who first introduced the term siderosis, although Lebet had previously demonstrated it experimentally, and Graefe and others had called attention to the fact that the rust color of the lens and iris was evidence of the presence of a piece of iron in the eye. As Bunge says: "The iron is dissolved by the carbonic acid gas of the tissues and the solution is diffused as a double carbonate of iron and precipitated in insoluble form by the oxygen supplied by the arteries." The iris becomes discolored a rusty brown, sometimes the cornea is discolored, as well as various layers of the lens. But the changes most disastrous to vision are those in the retina, which becomes degenerated, especially if the foreign body is in the vitreous. Von Hippel[21] also has investigated the condition carefully, and numerous reports of cases have been published, so that the condition is now fairly well understood clinically. The retina becomes highly atropic, showing changes very similar to those seen in *retinitis pigmentosa* and often becomes detached; the lens becomes cataractous and is often absorbed, even when the capsule is intact. In one of Von Hippel's cases the beginning of the process could be established two months after the injury, though the time varies from two months to two years and more. Whether this process of siderosis will take place or not in any case depends altogether upon whether the foreign body is completely encapsulated or not. In a case examined by Hertel[22], the foreign body was almost but not completely encysted. Yet siderosis with its disastrous effect on vision took place. It would seem, furthermore, from one of Von Hippel's cases that when the process has once well begun, the removal of the foreign body does not put an end to it, for he removed a piece of steel five months after the injury, yet siderosis progressed and the vision continued to fail. The size of the foreign body, moreover, does not seem to have any bearing on the subsequent changes, for in Hertel's case an extremely minute particle produced destructive changes. Sections of these eyes, after removal, are stained a deep blue color when soaked in a solution of ferrocyanide of potassium and dilute hydrochloric acid (The Perls Reaction).

Premonitory Symptoms of Siderosis.—In many cases a symptom, whose possible presence it is very important to remember, precedes the change of siderosis, viz., a high degree of hemeralopia (night blindness), or great impairment of vision if the illumination is poor. Vossius[23] considers this an important symptom in uncertain cases, and in one patient he made the diagnosis on this symptom alone and found and removed the foreign body. In 35 per cent. of the cases collected by Eisenberg[24] there was hemeralopia, which developed in one case in two months after the injury. If, therefore, we decide in a case like this to leave such a foreign body undisturbed, the patient should remain more or less under observation, and if vision begins to fail or hemeralopia develops, then an attempt should be made to remove the particle. This would probably be more difficult to do than if it had been removed immediately after the injury, as it would probably be more or less encapsulated.

The importance of keeping such a patient under observation is illustrated by a case of Hirschberg's[25] with an iron sliver in the retina, with almost normal vision, which he published in 1875. He did not remove it. In January, 1901, after twenty-six and one-half years, he saw the patient for the first time again. The eye was stone blind, with cataract and cyclitis, and according to the statement of the patient became blind within a year after the injury. So that it cannot be denied that an eye is not absolutely free from the possibility of danger as long as a piece of iron or steel remains in it.

Last June a patient was sent to my clinic through the courtesy of Dr. Gruening, which illustrated the effect of siderosis on the eye. The patient, an Italian, had previously lost his right eye, and a year before a particle of iron or steel had penetrated his left eye, and this was followed, so he stated, by progressive failure in vision, so that when I saw him he could only see movements of the hand and had to be led to the hospital. The iris was of a dirty brown color and the sclerotic had lost its whiteness, presenting a rusty brownish shade. Seated before the giant magnet he had great pain, and the eye became red in the ciliary region below when the magnet tip was placed here, but evidently the body

was more or less encapsulated, for we could not move it. Examination with the sideroscope was negative, but the radiograph revealed the presence of a foreign body in the lower outer quadrant of the ciliary region. I had decided to make an incision here and endeavor to extract it. But when, as a preliminary, I presented him with a little paper to sign, authorizing the operation with a full understanding of its possibilities, he disappeared and did not return.

If the foreign body should be lodged in the retina and the vision was seriously impaired, I think no one would question the wisdom of at once attempting to remove it.

After the foreign body has been removed, the eye may even then be lost through infection, and have to be enucleated. In some of these traumatic infections some surprising results have been reported by Haab and others by the introduction into the anterior chamber or vitreous of sterilized rods or disks of iodoform. In some cases a rapidly progressive suppuration has seemed to be checked and the eye saved from enucleation. When serious infection does not take place, the prognosis, so far as preserving the shape of the eye, is in many cases very good, and oftentimes very good vision is preserved, though this latter will depend on the character and location of the traumatism. Of course the entrance of the foreign body into the eye may have damaged it so seriously as to make its removal imperative. While a blind or almost blind eye is oftentimes much to be preferred to an artificial one, yet we must not forget the patient's other uninjured eye, nor attempt to keep a badly damaged or sightless organ at the risk of losing the other by sympathy.

Finally, how are we to interpret complete absence of pain when an eye which has been recently penetrated by a foreign body is brought up to the giant magnet?

1. The first and obvious conclusion is that there is no foreign body in the eye, or at least that if there is, it is not of iron or steel. But one must be exceedingly careful in not deciding this too quickly, for not infrequently only patience and perseverance will accomplish the end desired. If not at first successful, we must approach the magnet to the eye in every conceivable direction by having the patient look up and down, to the right and left, etc., for thus the pull of the magnet will operate in different directions, and be apt to loosen or pry the foreign body out. Repeatedly turning the current on and off quickly has the effect of jerking it. Sometimes we only succeed after repeated attempts on several successive days, in bringing the foreign body into view or eliciting the symptom of pain. We must not forget, furthermore, that there may be more than one particle of metal in the eye.

2. The body may be enveloped in a fibropurulent exudation in comparatively recent cases, or may be firmly encapsuled if it has lodged in the eye for any length of time, as months or years. Either of these may frustrate our attempts to elicit the symptom of pain or to remove the foreign body. The particle might be in an insensitive part of the eye (as in the lens), but the magnet usually quickly draws it into a sensitive part.

3. The foreign body may be so minute, or so deeply located in the eye, especially if it be enveloped in a clot, that the power of the magnet may not be sufficient to move it. Fehr[36] recently reported an extremely interesting case, seen an hour and a half after the injury, in which the foreign body perforated the sclerotic. The ophthalmoscope revealed a thin, small, bright piece of metal floating in the vitreous, but attached to a blood-clot leading to the wound of entrance and which moved about with the foreign body when the eye moved in various directions. (The particle was thus suspended a few mm. in front of the retina.) The sideroscope proved that it was iron or steel, and yet every conceivable manœuvre with the giant magnet failed to get it or tear it loose from the blood-clot in the vitreous. The attempt was repeated on the following two days, and on the fourth day Volkmann's new magnet was tried, but all failed to move the foreign body. All the magnets got so warm that the attempt had to be given up, and with Volkmann's new magnet the pole itself got so hot that one could not touch it, which showed some fault in construction. It was not until the eighth day that, during a seance the patient suddenly gave evidence of pain, and the ophthalmoscope now showed that the foreign body had disappeared from its previous position, and it was localized in the vicinity of the ciliary body, whence it was extracted not without considerable difficulty, weighing only 1 mg. In this case, had the media been more or less hazy on account of blood in the vitreous, for example, so that the foreign body could not have been seen with the ophthalmoscope, the attempt would probably not have been continued with such perseverance, if the sideroscope had not been used. This shows the delicacy of Hirschberg's sideroscope, for here the foreign body was exceedingly minute (weighed 1 mg.) and was back near the retina, and yet the reaction was quite positive. It should always be used in doubtful cases. To give an idea of the size of such a particle an illustration is here given of a piece of iron wire 1 cm. long, which weighs exactly 1 cg. That is, if this piece of iron is cut into ten pieces of equal size, each piece will weigh 1 mg., and yet this minute mass, even if way back close to the retina, as in this case, can be drawn out by means of the Haab magnet. (Fig. 3.)

4. Double perforation: The foreign body may have passed entirely through the globe and be partly or wholly in the orbital tissues. The great increase in the number of cases of double perforation reported in the last two or three years may possibly be somewhat dependent upon the growth of manufacturing, but to a much greater extent it seems to me upon the great improvement in our diagnostic methods, and the increased care with which these cases are investigated. Natanson[37] of Moscow has collected fourteen of these cases, and Hellgren of Stockholm reports six, and I have found three others, which makes twenty-three cases of double perforation. Of these twenty-three cases six eyes were saved with normal vision in one and more or less impaired in five. In five of these the diagnosis could be made by the appearance of the second perforation in the fundus, but it is to be remembered that sometimes when the media are clear what seems to be the point of exit in the fundus is only where the foreign body has impinged against the fundus, and thence rebounded into the interior of the eye somewhere. The large magnet or sideroscope would diagnose this condition, however. In eight of the cases the foreign body was found only after enucleation, and in several of them it is probable that the eye might have been saved had attempts at localization been made before searching in the globe for the foreign body. If the latter penetrates into the orbital tissues so that it is not in contact with the globe, it apparently does no further harm, and in no case was suppuration caused, so that the mere double perforation does not necessarily mean the ruin of the eye. But if the piece of metal remains in con-

tact with the globe, or possibly is sticking through *its* posterior wall (it was thus located in six of the eyes removed), a dangerous condition of irritation is produced destroying the eye by cyclitis, or causing sympathy in the other eye. In Berlin's case he had begun to enucleate the eye when in cutting the tendon of one of the muscles the foreign body accidentally caught between the blades of the scissors at the back of the eye, when it was seized with forceps and extracted; the muscles already divided were reunited, and all irritation in the eye subsided.

In all these twenty-three cases the large magnet failed to extract the foreign body, or diagnose its presence by pain, except one or two in which the piece of metal was partly in the eye and partly in the orbit. The sideroscope was used in thirteen of the cases, eight times with positive result. The *x*-ray was used in ten cases, and in all ten it was successful. In these cases of double perforation the foreign body is usually of relatively large size, so that the radiograph sometimes leaves no doubt that the foreign body is extra-ocular, but if the latter is very close to the walls of the globe it may be very difficult to say positively whether it is in or outside of the eye. As Hirschberg[28] says, "There is no pathognomonic sign of a double perforation, but we must be guided by negative symptoms. In recent cases the foreign body cannot be seen, though the media may be clear, and the test with the large magnet is negative; possibly also that with the sideroscope. In old cases there is no siderosis, which is suspicious if there is considerable deviation of the needle. But most sure is the *x*-ray. A proper consideration of all the symptoms alone will assure the diagnosis so as to prevent our overlooking a foreign body actually present and leaving it in the eye to the injury of the patient, or seeking for a foreign body not present in the eye, which is equally harmful."

To recapitulate briefly. We find that

1. An eye in which a piece of iron or steel is buried invariably deteriorates, and ultimately becomes blind (siderosis bulbi) if the foreign body is not removed, unless it becomes completely encapsulated. In many cases this degeneration is preceded by the symptoms of hemeralopia.

2. If the foreign body is in the anterior segment of the eye, the Haab magnet is almost universally used, at least to get the particle into the anterior chamber.

3. The injury in the great majority of cases, when it is in the anterior segment of the eye, is not attended with a prolapse of the iris, and the occurrence of this complication makes it probable that the foreign body has not penetrated the globe. This symptom, however, is not a reliable one in case the foreign body has made a large or irregular wound in the eye.

4. If the foreign body has penetrated into the vitreous, or posterior part of the globe, localization either with the sideroscope, or *x*-ray, had better precede any attempt to extract it, especially if the lens is still transparent. After the particle has been localized it can be removed by way of the anterior chamber with the Haab magnet, or by opening directly into the sclera near where the particle has been located. As to which is the better method to be employed in this class of cases, is still a matter of discussion among ophthalmologists.

5. If the symptom of pain cannot be elicited with the Haab magnet, this is to be interpreted as evidence (*a*) that there is no foreign body in the eye, (*b*) that it is enveloped, in recent cases, in a fibropurulent exudation, or a blood-clot (Fehr's case), or (in less recent cases) that it is firmly encapsulated, (*c*) that it has passed entirely through the globe and is lodged partly or wholly in the orbital tissues (double perforation).

DISCUSSION.—In the discussion of this paper, Dr. De Schweinitz of Philadelphia made a very important observation, viz., that in several cases of traumatic cataract which had come under his care during the last few years, the *x*-rays had revealed a foreign body in the eye of which the patient was ignorant, and that in these cases he had removed the foreign body before extracting the cataract. This observation suggests the importance of first examining all these cases of traumatic cataract with the *x*-ray so as to discover whether or not a foreign body is in the interior of the eye.

35 WEST FIFTY-THIRD STREET.

Cactus as Compared with Other Cardiac Remedies.—A. J. Mann says that cactus is contraindicated, in all visceral tumors, hemorrhages, active hyperæmias and all vasomotor lesions. In febrile state it renders good service to the heart by giving strength and nutrition, which is of great value when the fevers are long and exhausting, but it will not reduce the temperature like strophanthus, or the other arterial sedatives. It may be used in conjunction with those agents of a depressing nature when prescribed, or it may be combined with aconite, phytolacca, macrotys, colchicum, capsicum, helonias, avena, belladonna, pulsatilla, and many other agents to enhance their effects or modify their action. It is superior to digitalis in nontoxicity, noncumulative action, does not irritate the stomach and causes no spasm of the renal circulation or albuminuria.—*Medical Summary.*

WHEN AND HOW SHALL WE OPERATE FOR PROSTATIC HYPERTROPHY?*

By WILLY MEYER, M.D.,
NEW YORK.
PROFESSOR OF SURGERY AT THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL; ATTENDING SURGEON TO THE GERMAN HOSPITAL; CONSULTING SURGEON TO THE NEW YORK SKIN AND CANCER HOSPITALS, AND NEW YORK INFIRMARY.

THE advance made within the last few years in the treatment of the enlarged prostate gland has been so great that I think the time has come when we are in a position, on basis of our practical experience gained, to discuss intelligently the two most important questions connected with this highly interesting subject, namely: When shall we operate for prostatic hypertrophy and how?

The disturbing element in settling the first question, I think, has been the divergence of opinion regarding the propriety of advising the use of the catheter as a *routine measure*. If surgeons could agree on this point, I can see no reason why the indication should not be speedily cleared up.

As the matter stands, it could occur that at a recent discussion as to the best treatment of the trouble under consideration, the opinion was freely expressed, that we still are at sea with reference to the proper advice to be given to prostatics seeking relief. This view, to my mind, is no longer justified. The evolution of prostatic surgery has advanced sufficiently, I hold, to warrant us in taking a more determined stand in the matter. I think it is right for us now, to say: As soon as the catheter must be given into the patient's hands, the time has come when operative intervention should be urged.

The risks involved in self-catheterization are too grave to justify us in allowing our patients to assume the same. While it is true that prostatics *may* catheterize themselves with impunity, for years, even under most adverse external circumstances, it is also true, that catheterization, though in the hands of the most skilful surgeon and in spite of every possible aseptic precaution, may prove a menace to the life of the patient, even the very first time it is performed—all the more, of course, if regularly performed by the patient himself. The fact to be reckoned with then is, that it is absolutely impossible to foretell what the results of continued catheterization will be.

This uncertainty alone, it seems to me, ought to be ample argument against the propriety of advising the use of the catheter as one of the *surgical* procedures in the treatment of this disease.

I, therefore, hold that the *regular* use of the catheter by the patient himself should no longer be a routine advice.

Still I do not wish to be misunderstood. This dictum does not exclude the advisablility of a short period of catheterization in the hands of the attending physician, in the event of sudden, absolute retention so frequently met with in the course of the disease, and which is often soon overcome by the temporary use of the catheter.

I further do not say, and do not want to be understood to say, that the catheter has or should have no place at all in the treatment of prostatic enlargement. There are certain exceptions when its use is justifiable. For instance, we meet prostatics, especially among the well-to-do, intelligent class, who readily learn and faithfully carry out regular aseptic catheterism and vesical irrigation, and when neither patient nor physician is willing to take the risk of an operation, slight though this risk may be; or, there may be complications, such as advanced diabetes, chronic myocarditis, and contracted kidneys. Such patients may get along well with the catheter introduced once or twice in twenty-four hours, while operation might possibly mean death.

It is not this class of cases that my remarks have reference to. I speak of the rank and file of prostatics, the men who leave in the morning and return home at night, working for a livelihood for themselves and their families, and for whom it is impossible to observe the necessary asepsis in all its details. Here the family physician or surgeon should at least suggest an operation; he should explain its advantages as well as its dangers, and should *not* give the catheter the first place in the list of remedies at our disposal. So long as the catheter receives the *first* consideration, we shall not, I fear, arrive at any satisfactory solution of the question as to the best advice to be given a prostatic. The catheter must be relegated to the rear; it must be our last instead of our first resort—in the average case.

Then, too, the mortality resulting from long continued self-catheterization doubtless would be found to exceed that of any operative intervention now in vogue.

This point, viz., the discontinuance of advising the use of the catheter in prostatic disease as a routine measure, having been agreed upon, the problem would then be solved in a most simple manner—that is to say, operative intervention would be advised in every case as soon as regular catheterization becomes necessary.

As to the method of operation, the choice would lie between prostatectomy and galvano-caustic prostatotomy (Bottini's operation), the only two standard operative procedures now recognized.

Should the patient refuse operation of any kind, then, of course—but only then—the regular use of the catheter would be resorted to. Thus, one would *fall back* on the catheter as the only available means of relief, instead of *primarily advising* it.

Having stated my views as to the question "When shall we operate for prostatic hypertrophy?", I shall now proceed to discuss the *methods* of procedure to be employed.

Generally speaking, I consider prostatectomy to be the most radical, the most surgical procedure—in short, I believe it to be the most nearly ideal treatment for prostatic enlargement. If it be true—and we know that it *is* true—that the trouble of a prostatic is a mechanical one, that the obstruction caused by the enlarged gland is doing all the mischief—then it stands to reason that the total removal of such tissue represents the best cure.

Thanks to the arduous labors of many of our colleagues, the technique of the operation has been perfected to such a point that we are enabled, in most cases, to avoid future complications. The procedure is, therefore, a comparatively safe one, its mortality being estimated at 5 per cent. or less, surely not more than that of Bottini's operation.

Hence, I now advise prostatectomy wherever I find no contraindications, such as, for instance, advanced diabetes (5 per cent. sugar and more), pronounced anæmia, very soft gland, marked contracture of hips, etc. (personal experience), and have personally done the operation by the perineal route, in ten cases—in nine during the last eighteen months. I found the route to the prostate by way of the perineum to be the typical and safe operation which my former experience with the same in opening prostatic abscesses on antiseptic principles,* removing a sequestrum from the tuberculously inflamed

*Read, by invitation, before the Brooklyn Medical Society, and before the Harlem Medical Association.

**New Yorker medizinische Monatsschrift*, 1894, No. 1.

gland and evacuating the glandular tissue from within the capsule, for chronic gonorrhœal prostatitis (three cases) had taught me to consider it.

As far as the age of the patient is concerned, at which prostatectomy may still be safely done, I have extended the limit indefinitely. With other words, I consider there should be no limit, *the patient's general condition* being the only point to be taken into account when advising radical operation.

The dangers that might arise from general anæsthesia can be well overcome by employing spinal anæsthesia. The latter, I believe, has a great field in prostatic surgery in old patients, and will, no doubt, tend to widen greatly the indication for prostatectomy. In one of my patients spinal anæsthesia afforded me ample time to enucleate the prostate and extract a large calculus from the bladder. The patient was presented before the New York Surgical Society, cured, in January, 1903.

Superficial anæsthesia with ether, given by the drop-by-drop method, as well as with laughing gas, administered by a number of surgeons, when shelling out prostate glands of larger size by the suprapubic route, must also be mentioned in this connection.

Therefore, if to-day a patient with symptoms of enlarged prostate comes to me for advice, I proceed as follows:

I inquire as to the frequency of micturition and other subjective annoyances produced by the disease. I palpate per rectum to see if the gland can be diagnosed in this way. As regards this point, it should be borne in mind that in 33 per cent. of the cases such tumor is not discernible with the finger in the rectum, while intravesical inspection with the cystoscope reveals its presence, as also that of a trabecular bladder, the latter being, cystoscopically, the foremost pathognomonic symptom of the enlarged prostate. If the patient has never been catheterized before, I prepare him with quinine for two to three days, giving three times 8 grains per day, sometimes adding methyl blue, after which the catheter is introduced under due aseptic precautions, the patient having previously emptied his bladder as far as he was able. If the amount of residual urine is found to be considerable and the patient declares that something must be done to give him relief, I propose operative interference. I emphasize the superiority of prostatectomy, pointing out that it will produce the most satisfactory and lasting results. Should the cutting operation be refused, or I should have come to the conclusion that in the given case Bottini's operation is preferable, then I urge the latter. If both operations are refused by the patient, the catheter must, of course, be resorted to.

Cystoscopy I propose in all cases in which the kidneys are still in good condition. In the presence of advanced pyelitis and pyelonephritis, I rather abstain, knowing the dangers of intravesical instrumentation in such cases. Cystoscopy will readily show the presence of a vesical calculus or calculi, as well as their size, which knowledge often enables us to determine whether extraction through the neck of the bladder may be accomplished. Cystoscopy will also reveal the presence of a median lobe as well as the general configuration of the whole gland. It will thus greatly assist us, in establishing the indication for the operation, best adapted for the individual case. All of these points, of course, are of less value to the surgeon who employs the suprapubic operation only, in which event the finger will detect much of this interesting detail.

Cystoscopy, however, is absolutely indicated in that 33 per cent. of patients suffering from the symptoms of prostatic enlargement, but in whom rectal palpation does not show the presence of a tumor. Here one glance, with the prism within the neck of the bladder, and one turn of the instrument will show the intravesical prostatic tumor as well as the trabecular bladder.

As to the technique I employ in doing perineal prostatectomy, this does not vary much from that of other operators. I prefer the semilunar, pre-anal incision, the highest point of the curve corresponding to the lower third of the bulbous portion of the urethra. I consider this incision preferable to the transverse one that reaches the lower end of the symphysis, where the flap turned downward is too high to allow the catheter placed in the bladder for drainage to pass out straight. Some surgeons therefore divide this flap in the middle, place the catheter at the lower end of the incision and close the upper part again by suture. I have used the semilunar, pre-anal incision, as originally advised by the late Professor von Dittel of Vienna in 1874* for the last fourteen years whenever attacking the prostate by the perineal route, and see no reason, at present, to change it for the one made in the median line. It certainly allows the most satisfactory access to both lateral lobes, and does not injure any important structures, inasmuch as it is carried through the subcutaneous fat at either end only. After completion of the enucleation the wound is stitched up bilaterally. After the bulbo-cavernosus muscle is reached and its tendinous junction with the external sphincter ani muscle exposed and divided, a point so well described by the originator of the method in 1874 and 1889,† and later again by Zuckerkandl, ‡ the membranous urethra is easily reached by blunt dissection and incised on the staff.

By working bluntly backward on either side of the incision, the lateral lobes are at once exposed. If stones are present in the bladder these are primarily extracted after stretching of the vesical neck; or, if too large and hard, they may be crushed and evacuated through the prostatic urethra or removed by suprapubic incision. Now Young's metallic retractor—which I have used in my last cases to my greatest satisfaction—is introduced, opened, and the prostate pulled down. This retractor, I would mention parenthetically, is simple and clean and of great help to the operator. It permits of any amount of traction, enables the surgeon to always know when the walls of the urethra are approached and thus to avoid injury to the same; incidentally it works as an excellent hæmostatic by compression. Now the capsule of one of the prostatic lobes, preferably the right one, is throroughly incised, close to the prostatic urethra (1 cm. deep, according to Young). I have, so far, always used a straight, longitudinal incision. Young recommends that this incision be made slightly convergent toward the upper end in order to be quite sure that no injury to the ejaculatory ducts be done—a modification well worth adopting, as the slight deviation of the incision does not interfere with the subsequent enucleation. I then try, in as blunt a way as possible, to reach the nucleus or nuclei of the gland, which are carefully shelled out. In semi-soft and small glands this may at times prove difficult; but, with a little patience, can always be accomplished. Sharp retractors and forceps of various size may have to be employed. Of course, the larger and harder the gland, the easier the work. During all this time of enucleation, the retractor, either held by the assistant or by the operator him-

**Wiener medizinische Wochenschrift*, 1874, Nr. 16.

†*Wiener klinische Wochenschrift*, 1889, Nos. 21-23.

‡*Ibid.*, Nos. 28 and 29, 1891.

self, is pulling the prostate down into or toward the external wound, indicating where to stop in order to avoid injuring the prostatic urethra and bladder. Thus we are enabled to do at least the principal part, if not the entire operation, under the direct guidance of our eyes. On reaching the prostatic urethra inwardly, the prostatic tissue immediately adjacent, to it is left behind as originally advised by Rydygier* who called it "enucleation resection." As I have stated before, further experience will have to show whether this part of the prostatic tissue can be left intact and a cure effected nevertheless. Young's more recent observations regarding the preservation of this tissue, the "ejaculatory bridge," as he calls it, seems to bear out Rydygier in his claim that resection be preferable to enucleation of the prostate.

The other lateral lobe having been enucleated in the same way as the first and the median lobe, if present, having been reached through one of the two emptied lateral cavities and removed, I put a divided so-called gutter-drainage tube into the bottom of each cavity, filling the latter with strips of aseptic gauze, sufficient to control the hemorrhage. Then a single large drainage tube with a lateral hole next to the distal opening, or, better still, such a tube with a small-sized catheter tied to it by a few silk threads, is introduced into the bladder and carefully gauged, so that its distal end does not press against the posterior vesical wall. It is then fastened with a silkworm gut stitch to the upper border of the external wound, the corners of the latter closed by a few interrupted silkworm gut sutures and dressings applied. Only in patients suffering from a pronounced chronic vesical catarrh, permanent irrigation is instituted; otherwise the small catheter is plugged and continuous drainage carried out, same as in other vesical cases. Twice daily the bladder is washed with saline or sterilized weak boric-acid solution, followed by ichthargan in doses of increasing strength. The tampons and drains I generally leave untouched for five days, when the former are removed and the latter somewhat shortened, but left in place until the second principal dressing, which is done two days later. The catheter held by the silkworm gut stitch remains *in situ* for seven to eight days. After it is removed, I allow the patient to urinate through the perineal wound; if prostatic urethra and bladder have not been injured, the patient is able from the start, to retain his urine and empty his bladder at certain intervals.

From the twelfth or fourteenth day on, a sound of sufficient size to insure proper patency of the canal is introduced for a short time once or twice a week, preceded by irrigation with boric acid and ichthargan. After the removal of the sound, the patient is requested to pass the solution that was injected into his bladder. Later the patency of the posterior urethra is tested with the sound from time to time.

Older patients with chronic bronchitis are made to get up shortly after the removal of the catheter—that is, at the beginning of the second week; younger patients, when complicating pneumonia is not threatening, may remain in bed somewhat longer.

As regards the relative value of perineal and suprapubic prostatectomy, I do not think any definite decision can be rendered in favor of either, so far.

The tendency on the part of some surgeons to employ one method to the exclusion of the other, is unjustified. Both methods are useful and excellent procedures. The choice will probably depend largely upon the peculiarities of the case, and upon the inclination and practical experience of the individual operator. Although with the advanced technique of perineal prostatectomy also in coping with a large median lobe, and in view of the seeming drawback of the suprapubic operation, that it will always have to be done in the dark (more so, at least, than the perineal one), it would seem but reasonable to assume that the perineal route will eventually receive the preference.

Still future developments may prove this assumption to have been erroneous. So far it has been shown that prostates forming a tumor of some size can be rapidly and thoroughly enucleated by the suprapubic route.* But, on the other hand, we come across glands, especially among those of soft and semi-soft consistency, that have as nuclei tumors the size of a pea or small filbert and that cannot be shelled out of the surrounding tissues *en masse*. Such glands, I am sure, cannot be removed to advantage, if at all, by the suprapubic route, while if attacked by way of the perineum, they can be nicely enucleated. These last remarks have reference especially to patients operated upon in the earlier stages of the disease.

We therefore must learn to individualize and endeavor to determine with the help of all available diagnostic means (*before* resorting to the knife), which route seems best adapted to the given case. Principally, however, I think the choice will hinge upon the question of the possibility of preserving sexual power, provided, of course, this is a matter of import to the patient.

Personally, as stated before, I have done perineal prostatectomy in ten patients, with eight recoveries and two deaths, due to accidents beyond my control, as will be seen from the following brief histories regarding these two cases:

In one case death occurred on the operating table after the successful completion of the operation, as a result of suffocation. The narcosis was in the hands of a young, inexperienced narcotizer, and death could have certainly been averted, had a more experienced man conducted the anæsthesia.

In the other case death was due to an overdose of morphine. The patient, a man of eighty, was greatly debilitated, suffering from paralysis agitans and partial contracture of the hips. Septic conditions had developed in consequence of suppuration of the gland. The prostate was thoroughly shelled out at the patient's home, and on the third day after operation, when the patient was on the highway of recovery, an overdose of morphine was administered by the night-nurse, producing such profound symptoms of poisoning, that antidotes, etc., were of only temporary effect and could not save the patient.

Considering, that these deaths were due to circumstances in no way connected with the operation as such, I think I may with propriety claim my mortality in perineal prostatectomy so far to be nil.

A most important, and yet unsettled question, as just mentioned, is that of impotence following prostatectomy. Carefully collected, reliable data regarding this point with reference to the two routes—perineal and suprapubic—are still missing.

Of course, in the consideration of this point we must not confound impotence with sterility. The preservation of the ejaculatory ducts does not necessarily imply the preservation of the power of erection. A patient's ejaculatory ducts and posterior urethra may have remained absolutely intact during the operation, he may have emissions of semen through the normal channel, and yet may become totally impotent.

Centralblatt für Chirurgie, No. 41, 1902.

* At time of correcting proof: Within the last few weeks I have had this experience myself in six cases.

The cause of this most unwelcome sequela must, it seems to me, be looked for in the interference with the nerves, which induce the proper filling of the corpora cavernosa with blood. Future statistics will show, whether impotence is more frequently caused by the perineal or by the suprapubic operation. The decision of this question will, of course, greatly influence the surgeon in selecting the route, for, as mentioned before, either procedure has its good points.

In spite of all that has been said in favor of prostatectomy, the fact remains that there *are* cases in which special circumstances are present rendering prostatectomy contraindicated, or the cutting operation is absolutely refused—and such cases are by no means rare in our daily practice. It is in *these* cases that Bottini's operation should hold undisputed sway, and not resort be taken to the catheter as the only remaining means of bringing relief, as done by the opponents of Bottini's operation.

In a paper read by me before the last meeting of the American Surgical Association at Washington* I have tabulated my cases of enlarged prostate treated by Bottini's operation within the last five years, 59 in number. I was able to trace 34, which were reëxamined or heard from in April, 1903. Of these, 10, or 28 per cent., remained cured; 18, or 54 per cent., materially benefited; 6, or 18 per cent., were not improved. Of 15 patients who had used the catheter regularly, 10, or 66.6 per cent., laid the same aside permanently. The mortality of the operation was 6.9 per cent., *i.e.* 4 deaths as a direct result of operation in the entire series of 59 cases. It must be mentioned, however, that two of the fatalities occurred in the first 12 cases, when the instruments were rather poor and sufficient personal experience was lacking, one in the second and one in the third dozen of patients operated upon. In the last 23 patients there has been no death directly due to the operation. It is worth stating that these 59 cases were not selected ones, but were operated upon as they came along.

Of 23 cases that could be utilized with reference to the important question of the maintenance of sexual power after Bottini's operation, it was found to have been fully preserved in 20, or 86.9 per cent. It was alleged to have been more or less interfered with in three. This surely is a good showing compared with prostatectomy, especially with perineal prostatectomy.

Out of this series I have picked out the following three cases, in order to demonstrate what can still be accomplished by Bottini's operation in patients to whom life has become a burden and who could have been helped in no other way.

Case I.—Mr. H. H. H., sixty years, has had urinary trouble for the last eight years; of late very frequent and painful micturition and overflow at night. At times there was bilateral lumbar pain and rather profuse hæmaturia. Prostatectomy, as well as Bottini's operation, had been strongly advised against by a prominent surgeon on account of the co-existing advanced kidney trouble. The establishment of a permanent suprapubic fistula, that was suggested, was not consented to.

The patient came under my care on July 2, 1900. Physical examination at that time showed a man greatly depressed and in an extremely anæmic and weak condition. Spontaneous micturition was very painful and frequent, every thirty to forty-five minutes during the day; overflow during night. A most gentle introduction of Nélaton's soft rubber catheter produced intensely painful spasms and was immediately followed by hæmaturia. Residual urine—700 c.c. Rectal palpation shows prostate large and soft, and painful on compression; its upper border cannot be reached with the finger. Urinary analysis revealed a marked secondary affection of the kidneys. There was blood, a large amount of pus and mucus; hyaline and granular casts; cells from bladder and pelvis of the kidney. Amount of urea discharged in twenty-four hours—14 grams. *Diagnosis.*—Chronic pyelonephritis and cystitis. In view of the seriousness of the complications and the fact that a colleague had absolutely refused to do even Bottini's operation, it was but natural that I too should hesitate to do it. However, the patient, as also his devoted wife, well aware of the greatly increased risk of the operation, implored me to proceed and do the best I could under the circumstances. So I consented. Cystoscopy was omitted in view of the complicating pyelonephritis. On July 7, after the usual careful preparation, Bottini's operation was done under local eucaine anæsthesia and a suggestive general anæsthesia with alcohol and water.

Beak of the incisor, on exploring interior of bladder, did not strike a stone. After hugging the gland, the tip of the beak could be felt per rectum, 7½ cm. from the sphincter ani muscles, the distance between these muscles and the lower border of the gland being 3½ cm. In order to make the division as thoroughly as possible, the posterior incision was now carried to a length of 4½ cm.; that through right lateral lobe (which latter was found the larger of the two on rectal palpation) 3½ cm.; through left, 3 cm., both at an angle of 45°. A permanent catheter was left in the bladder. The patient stood the operation beautifully. There was not the slightest reaction. After ten days, during which the bladder had been irrigated twice daily, the permanent catheter was removed on trial, but the patient was unable to urinate spontaneously. It was, therefore, replaced and worn until July 26, or nineteen days after operation, when regular catheterization and vesical irrigation were begun instead. After a few days the patient began to pass his urine spontaneously, without pain, at regular intervals, 4, 5, and 6 ounces being voided at a time; but there was still residual urine, varying from 10 to 15 ounces. On August 5, or one month after the operation, 92 ounces were passed spontaneously within twenty-four hours.

When the patient called on me again, after a two months' stay at his country home, where he had been attended by a colleague and nurse, I was agreeably surprised to find him free from his former despondency, and in possession again of his old pluck, which, it was said, had always been a spec al characteristic of his. Some color had returned to his cheeks; his eyes were bright. He urinated every two or three to four hours in varying quantities without pain, and the hæmaturia had ceased entirely. The total amount of urine passed in twenty-four hours was 60 to 130 ounces, of which about two-thirds were voided nights, one-third during the day. There was some overflow during sleep, which was caught by a glass urinal placed between his legs. Bowels were normal. Residual urine, though present, did not annoy the patient. He remained in this good condition for the following two years, refusing, to my regret, a second operation. He never again suffered pain, nor did the hæmaturia return. He died in the spring of 1903, from the effects of his advanced bilateral pyelonephritis.

*"Prostatectomy and Galvanocaustic Prostatotomy (Bottini's Operation), Their Present Status in the Radical Treatment of the Hypertrophied Prostate Gland."—Medical Record, October 24, 1903.

This case beautifully illustrates what may still be accomplished by means of Bottini's operation in seemingly hopeless cases. This patient, before a great sufferer and an invalid in the true sense of the word, with a bilateral pyelonephritis so severe that an operation on the prostate had been refused by others, and unable, on account of intense pain and bleeding, to longer continue the regular use of the catheter, was, by means of Bottini's operation, transformed into a man who could again enjoy life, who attended to his business regularly, from morning till evening. Surely a brilliant result, even though the one operation had not entirely overcome the mechanical obstruction caused by the enlarged gland. Had I had my own way, a second Bottini operation would have been done three months after the first. As it was, I had to be contented with conditions as they were. Here prostatectomy most assuredly would have been absolutely out of question; only an operation of less magnitude, if any, could be attempted.

The next case to be narrated illustrates the usefulness of Bottini's operation in closing a persistent suprapubic vesical fistula that had resulted after cystotomy; it also shows most strikingly the beneficial effect of the operation upon the sequelæ of prostatic enlargement in general, in the presence of a co-existing marked pyelonephritis.

Case II.—Mr. X, seventy-five years old. First noticed trouble in micturition, fifteen years ago. Soon required catheter; vesical catarrh developed. In 1890 a prominent New York surgeon performed a suprapubic cystotomy with the hope of finding a stone. This expectation, however, was not realized; a suprapubic fistula remained, in which a tube was worn for two years. All vesical symptoms continued. Upon the advice of a surgeon at his home, the permanent tube was removed, and it was found that there was very little leakage above the symphysis. By catheterizing himself three to four times in twenty-four hours, the patient managed to get along tolerably well for a while. Soon, however, the bladder became very irritable. So one year later his doctor reopened the bladder and removed two phosphatic stones, snipping off, at the same time, a portion of the middle lobe of the prostate. After this the patient was much better for three years. Then the vesical symptoms again returned and the patient submitted to unilateral (left) castration, which was followed by a decrease in the size of the prostate, but brought no improvement in the symptoms. Lumbar pains, pointing to a complicating, bilateral pyelitis, were noticed during the patient's sojourn at the seashore in 1897. The physician there, evidently looking upon the trouble as urethral fever, advised discontinuing the use of the catheter, suggesting instead a female silver catheter of very small size to be passed through the suprapubic opening and to serve for vesical irrigation at the same time. This procedure was kept up for the next few years. However, the suprapubic fistula never was patent, a condition which was a source of incessant annoyance to the patient. In May, 1899, Bottini's operation was performed at a hospital in the patient's town, and he was discharged the day following. No improvement. One month later a second Bottini operation was done by the same physician. Twenty-four hours later fecal matter passed per urethram: a rectourethral fistula distal to the prostate gland had been established, and the same allowed a great deal of thin fæces to pass through the anterior urethra and external meatus.

When first seen by me, November 8, 1900, the small silver catheter was introduced by the patient through the suprapubic fistula about ten to twelve times in twenty-four hours. Sometimes he passed his urine in a fine stream through the suprapubic opening, but he was always wet, had marked tenesmus; frequent slight hæmaturia. Otherwise the patient is a well-preserved man, presenting a funnel-shaped suprapubic fistula which just permits of the passage of the small catheter mentioned before. Prostate per rectum is very large; upper end cannot be reached. There is intercommunication between the rectum and the membranous portion of the urethra, sufficient easily to admit the tip of the index-finger on rectal palpation.

In view of the exceptional history and complications of the case as well as the comparatively satisfactory condition of the suprapubic fistula, it will be readily understood that I was not much inclined to perform a third Bottini operation, as demanded by the patient, prostatectomy by either route being excluded by the patient's general condition as well as by the rectourethral fistula present. I very clearly pointed out to him the dangers and possible consequences of Bottini's operation in his present condition, suggesting that it might probably be best for him to leave good enough alone. However, he insisted; the permanent suprapubic leakage meaning such physical and mental torture to him, that he was willing to take any risk. I consented reluctantly, knowing full well, that the usual asepsis, which is of such great importance in the surgery of the uropoietic system, would be rendered impossible by that fistula.

Bottini's operation was done on November 27, after preceding internal medication. Spinal anæsthesia with cocaine was used. Irrigation of bladder through suprapubic wound. Then, with the assistant's finger compressing the rectourethral fistula, irrigation of anterior urethra, followed by the usual injection of sterilized paraffine. The prostatic incisor then slipped into the bladder with great ease. Before starting the operation, the interior of the bladder was carefully explored for a stone, with negative result. On trying to hug the prostate the beak slipped off; a second and third attempt was made with the same result. Diagnosis: large median lobe. Three incisions were made as usual, the posterior one being done twice.

The reaction was by far slighter than anticipated. Although, it is true, he developed epididymitis on the right side and an infiltration of the remnant of the cord on the left, his urinary organs were otherwise not affected. On the fourth day the patient was out of bed. Voluntary micturition through the urethra occurred for the first time within the last ten years on the eighteenth day after operation, but did not continue. On January 4, thirty-eight days after operation, the first larger amounts were voluntarily discharged through the normal channel, so that during the twenty-four hours closing on January 5 the patient had passed 32 ounces per urethram. A part of the urine, of course, always ran through the rectourethral fistula into the rectum. By introducing the catheter through the suprapubic fistula at regular intervals, the patient managed to keep himself perfectly dry.

A truss, as used for ventral hernia, with an air pad served as an additional safeguard against leakage. On January 9, 1901, the patient left for his home, his condition being greatly improved in every respect. Under date of January 17, his physician wrote me as follows: "Permit me to tender you my hearty congratulations for the good work you did in such a complicated case as that of Mr. X. He is doing well; the urethral flow is improving rapidly and he is walking out in the sunshine."

On the 4th of February the patient himself wrote: "The fistula has become so tight that I have difficulty in introducing the catheter. I stopped wearing the belt about a week ago; there is not a particle of leakage."

After enjoying this favorable condition for almost two years, the patient insisted upon having the rectourethral fistula closed. This was attempted at his home, but, unfortunately, without success. Soon afterward he died, as a result of his chronic trouble.

Thus a suprapubic fistula due to cystotomy in the presence of an enlarged prostate gland, having persisted for ten years, became definitely closed, and normal urinary drainage that had been suspended for the same number of years, was reëstablished by Bottini's operation, and that in a patient whose condition rendered prostatectomy as well as the continued regular use of the catheter through the normal channel impossible.

CASE III.—J. S., eighty years of age, was brought to me suffering from a far-advanced paralysis agitans with contracted hip-joints and absolute retention. His widowed daughter had been taught to catheterize her father, as the people were too poor to afford a trained male attendant. After months of faithful work the daughter had broken down under the strain, and then the question as to what might possibly be done for the patient became most urgent. As a matter of course, I was opposed to performing even Bottini's operation upon the patient, but the relatives insisted upon more than palliative work, being willing to take any risk. Thus, in the summer of 1902, Bottini's operation was done at the hospital; a very troublesome after-treatment followed. The result was that the patient got rid of the catheter absolutely, and now has very little trouble with his urinary organs.

These three cases will prove what may still be accomplished by means of Bottini's operation in otherwise positively hopeless cases, prostatectomy by either route being contraindicated and the use of the catheter having become intolerable.

What Bottini's operation can do in ordinary cases of prostatic enlargement, I have tried to show by the statistical data given above, covering a series of fifty-nine cases.

Surely, an operation that may be the means of accomplishing such excellent results should have the fullest and most careful consideration. To my mind the operation certainly does not deserve to be cast aside as worthless or unsurgical on merely theoretical grounds. It clearly should be classed as one of the surgical procedures for the radical treatment of the enlarged prostate gland. As recent contributions to the literature by some of our best men show, the truth as to its value is already being more generally recognized in this progressive country.

After all that has been said, I hold that the surgeon, in order to do justice to the prostatics entrusting themselves to his care, should train himself so as to be able not only to perform perineal or suprapubic prostatectomy properly, but also to do Bottini's operation. For, no one method of operating is applicable to all forms of prostatic enlargement; in other words, we must select the operation that suits the case.

1. *Conclusions.*—In view of the present advanced status of prostatic surgery, the catheter should no longer be advised as a *routine measure* in the surgical treatment of the disease under consideration.

2. Operative intervention should be urged as soon as the time for the regular use of the catheter has come.

3. Prostatectomy, being the most radical as well as the most surgical procedure, commands the first place in the treatment of the hypertrophied prostrate gland, especially since the technique has been perfected to such a point as to render the operation a comparatively safe one, the mortality having been shown to be less than 5 per cent.

4. The perineal route seems preferable to the suprapubic, for the reason that it enables the surgeon to do the operation more under the guidance of his eyes.

5. The choice of route in the average case will probably hinge on the question of preservation of sexual power, provided this point is of importance to the patient.

6. The patient's age, as such, does not furnish a contraindication to operation; it is his general condition merely, that has to be taken into consideration.

7. Where the effects of general anæsthesia are feared, spinal anæsthesia is indicated.

8. If the operation with the knife be refused or contraindicated, Bottini's operation should be advised, since it, too, yields excellent results.

9. Thus, we have two useful methods of operation for prostatic hypertrophy, viz., prostatectomy by the perineal or suprapubic route, and Bottini's operation, each holding its own place, and one complementing the other.

700 MADISON AVENUE.

A CASE OF HYPERPYREXIA WITH RECOVERY.

BY H. WALTON WOOD, M.D.,
TAUNTON, MASS.
ASSISTANT PHYSICIAN TO THE TAUNTON INSANE HOSPITAL.

AUTHENTIC reports of hyperpyrexia have been recorded, varying from 108° to 148° (Jacobi), but, excluding some cases of insolation and status epilepticus, the majority of others are attributed to hysterical disturbances, mostly occurring in females.

The case which is here reported occurred in a male who presented no stigmata whatever of hysteria, and gave no evidence of neurotic diathesis in the anamnesis. The patient was a well-developed, well-nourished and robust Nova-Scotian, twenty-five years old; habits good; and by occupation a night supervisor in the hospital.

The first symptom was a hard chill occurring at noon, corresponding to the middle of his sleeping hours. He was unable to sleep the remainder of the day, and I was called to see him about five hours after the chill. His temperature at this time was 102.3°; pulse 82, of good tone and rhythm; respiration 22, fairly deep, and free from pain. He complained of chilly sensations with a dull headache, and aching of the muscles of his back and back of his legs, accompanied by a general feeling of malaise. These symptoms were ascribed to the febrile condition. No sharply-defined pain was complained of and no definite location of pain. His tongue was slightly coated, but his bowels were said to have been regular and in good condition. Auscultation of his lungs demonstrated the vesicular murmur to be more pronounced than normal over the lower lobe of the right lung, especially marked during the end of inspiration and beginning of expiration. There were, however, no well-defined râles. Inspection showed both sides undergoing rhythmical and equal excursions. Percussion, negative. Palpation gave a slight increase of fremitus over the right upper lobe. There was no cough or dyspnœa. There was a slight relaxation of the walls of the pharynx with a small degree of congestion. Tonsils not enlarged. The heart was found to be in good condition. The sounds were normal, with no murmurs or arrhythmia

in action. Examination of abdomen, negative. Blood examination did not show any leucocytosis or organisms. The urine showed a slight trace of albumin, otherwise negative.

Four hours later his temperature had risen to 105.2°. A sponge bath, with an alcohol rub following, was given, and an ice-cap placed to his head, which reduced his temperature .5°. The next temperature was taken one-half hour later, or ten hours after the chill, and was found to be 107°. A sponge bath was again given with little, if any, effect upon the temperature. The patient at this time was very restless, tossing from side to side, and apparently was suffering from pain in the hypogastric region, as he was rubbing his abdomen with his hand, and had his thighs flexed. His pulse was 120, regular, small, and soft. His respiration was 36, and was not as deep as formerly, but regular.

His temperature, half an hour after his last sponge bath registered 112°. A control test was made, and the thermometer was found to register correctly, after which the patient's temperature was again taken and still found to be 112°. His respiration at this time was 90, very shallow and panting in character, with momentary cessations at irregular intervals, but did not simulate the Cheyne-Stokes' type as the excursion was regular, and did not fade gradually into the cessation, but would stop abruptly. Neither were the pupillary or pulse changes indicative of the Cheyne-Stokes' type. The pulse was 140 and regular, but thready in character. There was a slight flushing of the skin all over the body, which was covered with a light perspiration.

A tub of water containing large pieces of ice was then placed beside the bed, and his whole body was vigorously bathed with ice water, and rubbed with cakes of ice by two nurses. An ice-bag was placed over the præcordium, and ice was placed at the sides of his neck over the carotids, and under the arms. The temperature of the room was successfully lowered by raising the windows, with outside temperature at 15°. This treatment was continued for thirty-five minutes, and when his temperature was again taken, it was found to be 103.2° (a drop of 8.8° in thirty-five minutes).

The first indication of a reaction was noticed in the respiration, which became a little deeper and slower, followed closely by an improvement in the pulse. After the temperature had dropped a slight shivering was noticed, and a blanket was put around the patient and a hot-water bag at his feet.

His mental condition remained clear until the temperature reached 105°, when he became somewhat flighty in his talk, and appeared to be in a dreamlike confusion, from which he passed into a comatose condition. When the patient's temperature was 112° he could not be aroused at all. After his temperature began to fall he passed from this comatose condition into a delirium with auditory and visual hallucinations. During the delirious period he was totally disoriented for time, place, and persons, but comprehended with difficulty anything spoken to him. His mind was clear when his temperature again reached 102.5°.

One hour after the height of the fever was reached he had another rise to 103.8°, and remained at that elevation until the evening of the second day, when it dropped to 101.3°, where it remained, varying less than a degree a day, until the fourth day, when it reached 102.5°, but quickly dropped in a few hours to normal, from which it fell to 97.4° on the sixth day. After this it rose to normal, and did not again rise during convalescence.

He was allowed to sit up in bed after his temperature had remained normal for eight days, and returned to work in good physical condition three weeks after his first symptom. He had, however, requested to be allowed to resume his duties a week earlier.

The only drug treatment used in the case was a small dose of a coal-tar antipyretic at the onset, and a laxative of cascara sagrada three times during the course. His diet for the first few days consisted of egg-nog and milk, which was gradually increased by the addition of broth, eggs, toast, etc., until a regular diet had again been resumed.

He has apparently suffered no sequelæ except a catarrhal otitis media, which did not appear until after he had resumed his duties.

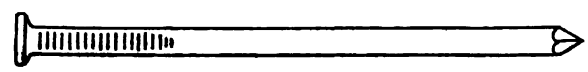
CASE OF NAIL IN THE DEEP URETHRA.

By G. FRANK LYDSTON, M.D.,
CHICAGO.

PROFESSOR OF SURGICAL DISEASES OF THE GENITOURINARY ORGANS, MEDICAL DEPARTMENT, STATE UNIVERSITY OF ILLINOIS; SURGEON TO ST. MARY'S AND SAMARITAN HOSPITALS.

A MAN, thirty years of age, married, laborer by occupation, was brought into my office by his physician with the following history:

Twenty-four hours previously the patient inserted a tenpenny wire nail, head first, into his urethra, for purposes best known to himself. The nail slipped from his fingers and was swallowed up by the urethra. Some hours later, becoming frightened, he consulted his family physician, who made persistent but ineffectual attempts to remove it. As a result of the irritation of the foreign body, and the traumatism incidental to attempts at removal, urethral hemorrhage and inflammation of the entire penis had developed. There was partial retention of urine. I decided that it would be unwise to introduce instruments into the urethra under existing conditions, until I had made an effort to locate the nail by palpation. Careful examination of the entire course of the urethra failed to discover the foreign body until the finger was introduced into the rectum, when the nail was readily felt, and could be



Nail Removed from the Deep Urethra.

outlined with a clearness which would have been surprising to one unfamiliar with the palpation of foreign bodies in the deep urethra. The nail lay diagonally along the canal, with its point embedded anteriorly in the right side of the wall of the membranous urethra. The head of the nail apparently lay just within the vesical neck, where it could be felt quite distinctly. The question now arose as to how best to remove the foreign body. As the point was embedded in the urethral wall, it was obvious that some difficulty would be experienced in dislodging it. In so dislodging it there was danger of pushing the nail into the bladder, which would require a cystotomy. The location in which the nail was found was a very fortunate one, and it seemed unwise to send the patient to the hospital, there being danger that the foreign body would become dislodged and enter the bladder on the way. The patient was poor and could ill afford the time and money necessary for the sojourn in the hospital which a cystotomy might demand. Taking the foregoing points into consideration, I considered it best to perform immediately a perineal section.

I placed the patient upon my office table, and after making the skin of the perineum aseptic, injected in the proposed line of incision a few drops of a one per cent. solution of cocaine. A small quantity of 4 per cent. was injected directly into the urethra. A small incision was made in the perineum

upon the point of a medium-sized urethral sound. The incision in the urethra was just large enough to admit the tip of the index-finger. The opposite index-finger being placed behind the head of the nail, *from* within the rectum, it was gradually worked loose from the point of impaction in the membranous urethra, and worked forward until it could be felt by the finger in the perineal wound. The latter finger was replaced by forceps and the nail withdrawn. The entire operation required less than one minute from the time the cutting began. Three catgut stitches were taken in the urethra, and the patient sent home on the street car in company with his physician, who was instructed to pass the catheter at regular intervals. Recovery was complete and rapid.

The nail removed was the ordinary wire nail, of the size known as the tenpenny. Its form and size are shown in the accompanying illustration.

The case is an interesting one, as showing especially the readiness with which the foreign body could be felt from the rectum, and the ease and simplicity with which a perineal section can be performed upon the surgeon' office table in cases of emergency.

CHEMICAL AND PHYSIOLOGICAL ACTION OF THE POTASSIUM CHLORATE AND IRON MIXTURE.

By W. R. DREYFUS, A.B., Ph.D.,
NEW YORK.

CHEMIST TO THE DEPARTMENT OF PUBLIC CHARITIES OF THE CITY OF NEW YORK, AND CONSULTING CHEMIST TO BELLEVUE AND ALLIED HOSPITALS.

I believe there is no remedy which is better known to the medical and pharmaceutical profession, or which has become more of a "specific" in medical practice than the chlorate of potassium and iron mixture, popularly known as "Jacobi's Special." The formula and directions for its use are as follows:

Potassii chloratis	80 gr.
Tinct. ferri chloridi	160 ♏
Glycerini	fl. 2 ♁
Aquæ	q. s. ad fl. 8 ♁

Use as a gargle in doses of ½ fluidounce; internally for children from two to six years old, one teaspoonful every hour if required.

The value of chlorate of potassium gargles, also of ferric chloride as styptics, respectively disinfectants, are too well known to be set forth here. What has, however, made the combination of chlorate of potassium and ferric chloride so interesting is that neither of these chemical agents produces the same gratifying results when used alone, or when employed alternately. No matter whether diphtheritic serum is used or not, 50 per cent. of all physicians still rely on this remedy as a great aid in combating the bacillus diphtheriæ. As it is therefore a fact that neither chlorate of potassium nor ferric chloride produces the same results as their combination does, what explanation can be advanced for the antigermicidal action of this compound?

The liquor ferri chloridi of the U. S. P. contains at least 5 per cent. free acidum hydrochloricum U. S. P., which is equal to 1, 6 per cent. by weight of absolute hydrochloric acid; the tincture of ferric chloride contains about 0.4 per cent. of absolute hydrochloric acid. I take it for granted that the prescription is dispensed *lege artis*, *i.e.* that the tincture of ferric chloride is not added to the chlorate of potassium. In the latter case the free acid besides the acid salt (ferric chloride) would set free the chloric acid ($HClO_3$) from chlorate of potassium under decomposition. On the other hand, if the chlorate of potassium be dissolved in water and the ferric chloride added, no reaction will be noticed; the same reaction, however, takes place, only with the exception that the chloric acid set free out of a portion of the chlorate of potassium remains stable in the cold aqueous solution. There is present, therefore, in a well-prepared solution of "Jacobi's Special," besides the chlorate of potassium and the tincture of ferric chloride, some undecomposed chloric acid. At a higher temperature and in contact with organic matter, the chloric acid is split up into perchloric acid, chlorine peroxide, and water according to the following equation:

$$\underbrace{3\,HClO_3}_{\text{Chloric Acid}} = \underbrace{HClO_4}_{\text{Perchloric Acid}} + \underbrace{2\,ClO_2}_{\text{Chlorine perox.}} + H_2O$$

Such a decomposition probably takes place when a solution is employed for medication. In contact with the bacillus diphtheriæ the temperature of the solution is raised, and some of the water is withdrawn. All chlorine derivatives, but especially chlorine peroxide, are fatal to bacteria, and especially to the bacillus diphtheriæ. While the germicidal power of chlorine peroxide is greater than that of chlorine itself, it is milder and more innocuous to higher animal life.

I do not venture to assert that the specific action of "Jacobi's Special" is due only to the energetic disinfecting power of chlorine peroxide in the nascent state, but the explanation above given is in all probability correct.

A CASE OF TURPENTINE POISONING.*

By E. D. NEWMAN, M.D.,
NEWARK, N. J.

D. W., aged fifty-seven, appeared at my office on November 30, 1903, with a history as follows: he is married, and has been working as a varnisher. Six days before I saw him, while going to his employment, he felt slightly nauseated; on his essaying to speak, as he puts it, "he got stuck;" he knew the words, but could not enunciate them; on his return to his home, his wife noticed this loss of coördination, and also his decided thickness of speech; she likened it to that of a drunken man; he had noticeable incoherence of ideas, decided exhilaration of mind, and diminished muscular strength.

On his appearance at my office, he informed me that he had been suffering for some weeks with frontal headache; that on the two days previous, at about 11 P.M., he had feelings of smothering. For some days he suffered with irritability of the bladder. There was no blood nor pain when passing his urine, but frequent desire; eructations were frequent, no purging, rather slight constipation; labored breathing, and the bronchial secretion was increased; no increased sexual appetite. When he was eating, at times the tongue had a tendency to go between the teeth on the right side of the mouth; the taste was decidedly impaired, and he could not, if blindfolded, tell one article of food from another; in swallowing, it seemed as if something wanted to go down beside the food; the mouth looks reddened at the margin of the gums with some white deposit. He could not blow air through the right nostril, but on examination I found the cavity patent; on attempting to read, he did it in a hesitating way, and with thickened tones and many lisps; such letters and sounds as are produced when the tongue is pushed against the teeth were the ones noticed as most affected (c, s, z, th, tt). On further questioning I learned that about twelve years ago he had an attack somewhat similar in character; at that time he could work but one-half of the regular period, urinating frequently, sometimes as often as twelve times an hour; the urine contained blood and caused pain in passing;

*Reported at the Physician's Club, of Newark, N. J., January 8, 1904.

he was nervous and morose, and had the same sensation in swallowing as in the present attack; he also had bleeding from the gums; the arms and legs were not affected in either attack.

He had been working as varnisher for about nine years when he had the first attack; he ceased working as such, when he began to recover and remained well until this attack; about June 1, 1903, he again started to work as varnisher, and this attack began about five months after his second attempt at this trade. His urine had the odor of violets and remained fresh and sweet, with no evidence of decomposition for 120 hours, in a room with an average temperature of 70° F.

As is known, varnishes are generally made in one of three ways, with oil, spirits, or turpentine. This patient used the latter, and thus occurred the turpentine poisoning. The points of interest are:

(1) The susceptibility of the patient.
(2) The acute onset.
(3) The profound poisoning.
(4) The poisoning by inhalation.
(5) The extreme rarity of the case.

81 New Street.

THE SIMULTANEOUS OCCURRENCE OF TYPHOID AND MALARIAL FEVERS IN THE SAME PATIENT.

By V. E. WATKINS, M.D.,
Medical Department, U. S. Army Fort Miley, California.

In an article on typhoid and malarial fevers at Chickamauga, appearing in the *Journal of the Association of Military Surgeons* for February, 1904, the writer remarks: "It is much to be desired that a positive statement might be made as to the co-existence of typhoid and malarial fevers in the same patient."

The occurrence of these two diseases simultaneously in the same patient is so rare as to be almost a medical curiosity; but that such a combination does occur is an indisputable fact.

Two well-established cases came under my observation in the fall of 1898. Both patients were soldiers who had served in Cuba, where the malarial infection was probably contracted.

The first case was admitted to hospital, Fort McPherson, Ga., on August 30, 1898. The temperature was high and there were chills at irregular intervals during the month of September. The typhoid-fever symptoms in this patient were not marked, but the diagnosis of a mixed infection was confirmed by the demonstration of the estivoautumnal organism in the blood, and by the obtaining of a positive Widal-reaction.

The second case was that of a private of the Hospital Corps, who had been an attendant on typhoid-fever patients for some two months prior to his admission to hospital. About three months had elapsed since his return from Cuba, where he had had an attack of malarial fever. He was admitted as a patient to hospital on December 1, with a well-marked case of typhoid fever. Widal reaction was positive. During the third week chills occurred on alternating days with irregularity in the temperature. A microscopical examination of the blood at this time showed the presence of the tertian organism.

The clinical picture of the double infection is not characteristic, but will depend upon which process is the more active. A correct diagnosis from the symptoms alone is well-nigh impossible, and recourse must be had to the microscope.

Dedication of a Hospital.—The addition to St. Francis' Hospital, Freeport, Ill., built at a cost of $47,000, was dedicated June 8, by Archbishop Quigley.

Technique for the Application of Bier's Venous Congestion.—Henle says that one of the reasons why this excellent therapeutic measure has not attained greater popularity lies in the technical difficulties of its application. The proper degree of venous stasis is reached when what is known as "hot congestion" is produced—that is, the venous return is checked only sufficiently to cause a feeling of warmth and tingling. If the constriction is too tight, "cold congestion" is produced which is therapeutically ineffective and is very painful to the patient. It requires much skill and patience to adjust a rubber bandage so that exactly the proper degree of compression results, and the author employs a modification of the Riva-Rocci sphygmomanometer to accomplish the purpose. The extremity is encircled with a closed tube of rubber connected with a mercurial manometer and with a bulb for inflation. By forcing air into the tube the required compression can be easily produced and accurately graduated, while the manometer reading gives a record of use in making subsequent treatments.—*Zentralblatt für Chirurgie*, April 2, No. 13, 1904.

Vaginal Cæsarean Section.—Dührssen continues to advocate very warmly this method of rapid delivery by deep cervical incisions or by vaginal cæsarean section. About one hundred cases of the latter operation have now been reported, and the author considers it one of the most desirable means of rapidly emptying the uterus, particularly in eclampsia. In cases in which some dilatation has already taken place so that the internal os is obliterated four incisions carried up to the vaginal vault will usually give abundant room for delivery. To avoid complications it is important to make the posterior incision first. When the cervix is wholly undilated, splitting up of the anterior and posterior uterine walls, together with the anterior vaginal wall, can be safely performed by any gynecologist and makes delivery easily possible. The posterior incision is an essential part of the technique, and the difficulties some authors describe have been largely due to attempts to deliver through only an anterior incision. Prophylactic nicking of the perineum is also often necessary in primiparæ in order to save injury to the pelvic floor. The author has not given up the use of the metreurynter, however, but always makes a trial with it before resorting to the more radical procedures to which his name is attached.—*Zentralblatt für Gynäkologie*, April 2, No. 13, 1904.

Notes on the Treatment of Neuralgia by Injection of Osmic Acid.—G. A. Wright calls attention to the fact that most of the surgeons who have used osmic acid have injected it more or less at random, without exposing the nerve trunk. Such a method is quite sufficient to account for irregular and defective results, and it is also remarkable that so little is said of any ill effects considering the very marked changes that osmic acid produces in the tissues. In all the writer's cases he has exposed the nerve and injected a 1½ or 2 per cent. watery solution into the trunk or into branches. Sometimes the injection has been both toward the periphery and toward the center, and the acid has generally escaped more or less freely into the tissues immediately around the nerve.. Most of the writer's cases are much too recent to attempt to draw any conclusion as to the permanent value of the method. It is also impossible to eliminate the effect of the exposure and the mechanical results of the manipulation and puncture of the nerve, and in some cases of unintentional section by the trephine. The writer believes, however, that if this method is employed, the nerve should be fully exposed. He also believes that the immediate results in his cases, as regards both harmlessness and at least temporary relief, quite justify the use of the plan before resorting to any such severe procedure as excision of the Gasserion ganglion. It must be remembered that pain may continue for some days or even longer after the injection and then pass off. The writer then appends a list of cases.—*Medical Chronicle*.

THE PRACTICAL FACTOR IN IMMUNITY—BACTERICIDAL OR CONSTITUTIONAL?

THE perusal of an article in the *Journal of Medical Research* for May, by Dr. A. B. G. Nicholls, demonstrating the presence of bacteria in the mesentery of normal animals, is calculated to rouse thought on the ever-living question of immunity from disease. The author cited shows that in many of the lower animals bacteria are present within the various cells and capillary channels of the mesentery. Adami had previously observed this vital absorption of bacteria, so to speak, in normal, as well as cirrhotic human livers, and Nicholls has found it equally in the normal kidney in man and the lower animals. He says: "These facts strongly suggested that bacteria were constantly passing from the various epithelial and mucous surfaces of the body into the interior of the organism, whence they were taken up by the blood or lymph and carried to the various organs. In the case of the liver the presumption was that the bacteria were taken up from the lumen of the bowel and carried by the portal circulation directly to the liver, or else that they were removed by the lacteals and lymphatics and thus discharged into the blood, whence they reached the liver in the process of excretion."

By special technique (which included instantaneous killing and rapid removal and staining in thionin), and examination under a Reichert or Zeiss 1–18 or 1–20 objective, a 1–12 not giving sufficient magnification, Nicholls found in the rabbit's mesentery certain bodies which he considers bacteria, giving his reasons at some length; and an identical condition of things was found to exist in the mesentery of the guinea-pig, cat, and dog. Nicholls says: "Of late years evidence has been accumulating that in healthy animals bacteria are constantly passing in from the various surfaces of the body to become lodged in certain tissues, notably the lymph glands, and the discovery that microorganisms can be demonstrated in the mesentery affords one link in the chain of proof which has hitherto been wanting." Macallum has shown that the leucocytes take up iron from the intestine and carry it as far as the villi, and the capillaries of the liver and spleen. Ruffer, examining the intestines of healthy animals for bacteria, found leucocytes on the free surface and between the epithelial cells, many of which contained bacteria, while crowds of microorganisms could be demonstrated within the Peyer's patches. Recently several observers have found the pneumococcus and B. tuberculosis in the peribronchial glands of healthy animals, and Nicholls has observed microorganisms in the healthy mesenteric glands—observations which are in accord with those of Bizzozzero, Ribbert, and Adami. "Collectively these studies appear to afford conclusive proof that in healthy animals phagocytes pass out constantly to the mucous surface of the intestine and return loaded with food particles, fat, bacteria, etc., which they deposit eventually in the various organs. One path of entry is certainly through the lacteals and lymphatics, but another may be through the radicles of the portal vein."

Finally, to complete the tale of evidence, Ford has obtained cultures from healthy organs, as has also Nicholls. The latter concludes by saying: "That bacteria are constantly passing from the various surfaces of the body to the interior of the tissues, in which they can be demonstrated by special methods, is opposed to the long standing opinion that, in health, the various epithelial surfaces afford a complete protection against the entry of bacteria into the organism. Indeed, this conception that in health the organs are sterile has been accepted as a fundamental fact in our views regarding infection. Even now, although so many separate observers have brought forward clear evidence indicating that this is a false conception, the old doctrine regarding the sterility of the normal organs is still being taught. We found it laid down clearly in a textbook of general pathology by a well-known pathologist across the water, published within the last few weeks. I cannot but think that if the simple experiment here described be repeated with reasonable care, it must establish the contrary view beyond cavil; the view, that is, that the normal organs are not actually but only potentially sterile; bacteria are carried into them, but, in health, undergo a fairly rapid destruction."

These results seem to offer much food for thought. Of late years the bacteriological tree has borne much fruit, and to-day one of its most popular products is the conviction that the hygienic millennium is to be furthered by a public anti-bacterial crusade. Without denying some value to the efforts now being made in this direction in many places, the results likely to accrue would, in our opinion, be rather dearly purchased if the pursuit should lead us to forget that after all the final question is one of the physiological personal equation; the factor which used to be called, somewhat vaguely perhaps, "individual resistance," and which we now describe as the sum total of the phagocytic and antitoxic actors. Certainly one who has served in a chronic hospital can, in the case of an old patient succumbing to a "terminal pneumonia," much more easily think of him as having had the microorganisms present for a long time, and that a point was finally reached where "resistance" ceased to operate, than to believe that just that day for the first time he came in contact with the etiological organism.

EARLY BLOOD CHANGES DIAGNOSTIC FOR TYPHOID FEVER.

FOR a long time it has been known that the absence of an increase in the leucocytes speaks in favor of typhoid fever as against suppurative and some inflammatory affections. In the last number of the *Deutsches Archiv für klinische Medizin*, Drs.

Ludwig, Kast, and Carl Gütig give the results of their examinations of the blood in 105 cases of typhoid, with special reference to the question of its availability for *early* diagnosis. For this purpose they analyze the conditions found at the first examination. Of the 105 cases, 97 (or 92.4 per cent.) showed a total leucocyte count of less than 7,000; 6 cases showed between 7,000 and 9,000; and only 2 cases showed above 9,000. These figures are for all the cases, taken without reference to whether they were complicated or not. Forty of the cases were complicated; the lesions being severe bronchitis, lobar and lobular pneumonia, suppurating bed sores, severe icterus, ulcerous colpitis, gonorrhœal urethritis, abscesses, cystitis, etc. In nearly all of these case too, the numbe of leucocytes in the early stages of the typhoid was under 7,000. Two cases of abscess showed an increase in the leucocytes, and the same hyperleucocytosis was seen in individual cases between the forty-first and forty-sixth days of the disease, after the fever had almost or quite defervesced. ne accident, however, was specially apt to bring about a leucocytosis, namely, hemorrhage. One of the three cases showing as many as 29,000. The experience of the authors then justifies the in laying down the rule that, in the vast majority of cases, complications do not alter the natural typhoid blood state of hypoleucocytosis, and that this is especially true of the earliest stages of the disease; but that the leucocyte count is valueless for differential purposes, if a short time before it is made a severe hemorrhage has occurred. With some limitations given below, then hypoleucocytosis points toward typhoid fever, and the more distinctly the more marked its degree, a count of less than 5,000 being especially significant. Kast and Gütig's results are, therefore, in complete accord with those of Kühn, who found the same condition in 92 per cent. of his cases, and who considers that for early diagnosis this sign is entitled to outrank all others. On the other hand, the existence of a hyperleucocytosis tends to exclude typhoid fever, and that disease is negatived with the greatest probability by a count of over 12,000.

The other conditions which, in Kast's and Gütig's experience, have shown a low leucocyte count, are: Measles, malaria, pulmonary tuberculosis, Banti's desease (two cases), severe anæmia, miliary tuberculosis (two cases out of eight), and overpowering general infections; the degree being slight in the first three, and considerably too high in the remaining conditions. In particular, as regards the differentiation of typhoid from tuberculous meningitis, the high normal or increased leucocytosis in the latter disease, is an important point. And between typhoid and severe sepsis or pneumonia, the shifting between high and low in the last two conditions contrasts with the persistently low count of typhoid. With a low leucocyte count in anæmia, for the exclusion of typhoid great caution is required, as the co-existence of the two conditions under mask of a similar blood condition, is by no means impossible.

As regards the comparative merits of hypoleucocytosis, and the clumping of the bacteria which constitutes the Gruber-Widal test, the authors award the greater weight to the latter sign when available. The value of the condition revealed by the blood count, however, lies in its frequently being available at a time when the Gruber-Widal reaction is not obtainable. In fourteen of their cases the blood had already taken on the characteristic typhoid picture, though it was as yet impossible to get the Gruber-Widal reaction.

The authors also point out the low numbers that obtained in the fatal cases, and their experience leads them to believe that the higher figures maintained constantly for a long time, afford grounds for a favorable prognosis. They found a fall in the number of lymphocytes especially ominous. And the same was true where toward the end of the fever complications depressed the leucocyte curve further.

The condition of the blood in paratyphoid fever is, in essential particulars, the same as in typhoid.

EPIDEMIC TRICHINOSIS; EOSINOPHILIA, AND SPLENIC ENLARGEMENT.

In the *Deutsches Archiv für klinische Medisin* for April 14 last, Dr. Karl Schleip gives the results of his personal investigations of an epidemic of trichinosis which originated between August 19 and 26, 1903, at Homberg and environs. The epidemic was a mild one. While in former epidemics the mortality had reached as high as 30 per cent., in the present one no death occurred, though during the third and fourth weeks the prognosis in many cases could not have been favorable. The conclusions reached by the author are that the clinical symptoms in trichinosis are not sufficient to establish a certain diagnosis of that condition. Especially is the diagnosis difficult in cases occurring separately much more so than during an epidemic. Indeed the occurrence of numerous unrecognized sporadic cases shows that such cases are rarely diagnosed, the disease being perhaps unrecognizable. In the direction of a clearer recognition of the disease the Homberg experience bids fair to be of practical value. Two facts of great value were determined: First, that a distinction from typhoid fever based upon the presence of an enlarged spleen, the presence of which has been regarded as a valuable differential point in favor of typhoid, is worthless, as out of forty-six cases repeatedly investigated the spleen was enlarged in thirty-eight, a percentage of 82.6; and, secondly, that in the presence of a marked increase of the eosinophile leucocytes we have a differential mark that amounts, for practical purposes, may be regarded as pathognomonic. For, although apart from its occurrence in helminthiasis generally, eosinophilia is known to occur in some skin diseases (pemphigus, acute dermatitis, chronic dermatitis herpetiformis, etc.), still these conditions are easily discriminated from trichinosis clinically. The existence of eosinphilia in trichinosis was first observed in 1896 by T. R. Brown, who pointed it out as specific for the character disease. Since then it has several times been found. The chief value of this symptom lies in its being a practically certain diagnostic mark, and, moreover, one which is available for diagnosis at a time when the trichinæ have not yet migrated into the muscles and within reach of the spear. In the Homberg epidemic the eosinophilia occurred regularly, and was of a high grade.

As regards the individual stages of the disease, too, the fluctuations in the relative proportions of the different leucocyte species is characteristic.

These fluctuations are conditioned, first, by the action of the metabolic products excreted by the trichina on the places of formation of the leucocytes; and, secondly, through an alteration during convalescence of the lymphatic apparatus, and probably also through a disintegration of the eosinophile leucocytes. During the disease, in many cases a leucocytosis appears; in almost all cases a high-grade eosinophilia is present, while the neutrophiles show, both percentually and absolutely, a diminution. In the stage of convalescence a marked increase takes place in the lymphocytes, with a simultaneous deluging of the blood with blood-plates. Coincident with the diminution of the chemotactic matters excreted by the trichinæ, the neutrophile cells show an effort to regain their normal numbers, and the eosinophilia gradually vanishes. In the peripheral blood the eosinophilia have the normal appearance. From the rarity of transition forms between them and the basophiles, it is impossible to draw any certain conclusion as to the origin of the eosinophile cells.

The interstitial myositis in trichinosis is strongly marked. It is conditioned by a heightened immigration of eosinophile leucocytes to these foci, which probably represent the track of the wandering parasites. The stronger gathering of the eosinophiles in the muscles is due to the fact that the specific irritation is here greater than at other points. The absence from the muscles in trichinosis of immature eosinophiles, together with the complete absence of eosinophiles in other forms of myositis, speaks against the view that the esoinophile granules originate through a disintegration of the muscle substance.

The regularity of the occurrence of eosinophilia in all diseases conditioned by the presence of helminths, even that of helminths which do not migrate into the body, and consequently do not produce myositis, points much more to the conclusion that the leucocytosis is a result not of the myositis but of the helminthiasis, that is to say, of a chemotactic working of helminthic products.

As regards the degree of enlargement of the spleen, measurements of 12.9, 10.5, 7.5, and 14.8 centimeters were not rare. All measurements were made in the erect posture. Upon recovery the enlargement disappeared.

With respect to the length of the incubation period many cases developed the day following ingestion of the infested meat. Indeed with some, digestive disturbances showed themselves immediately after ingestion. The longest period was eleven days; the more general three to six days.

The Dangers of Improperly Sterilized Milk.

Women, nowadays, are generally glad of any excuse in order to avoid feeding their children at the breast. Thus they appear only too willing to believe implicitly the specious advertisements of the manufacturers. Sterilized milk has gained a great reputation as being freed by the process it undergoes from injurious germs, and is given freely to children in the belief that such is always the case, and that milk treated by sterilization is a harmless and nutritious food. Unfortunately, however, the so-called "sterilized" milk is not frequently all that its name implies. Putting on one side the contention that by sterilization milk is deprived of some of its best properties, there are other features in connection with sterilized milk that are worthy of notice.

Dr. William Robertson and Mr. William Mair describe in the *British Medical Journal*, May 14, the result of investigations made by them into the bacteriology of sterilized milk. The conclusions reached are these: The first and obvious conclusion arrived at, say the authors, is that the designation "sterilized" milk, as applied to that sold from corporation depôts, is wrong and misleading, and we would suggest the substitution of the term "Milk Prepared for Infants." In this way there would be no sailing under false colors, nor will undue confidence be placed in the keeping qualities of infant's milk. (2) Every customer should be carefully instructed as to the necessity for keeping the milk in as cool a condition as possible. This instruction will especially be necessary in summer when the temperature often exceeds 70° F. (3) Faith in the powers of our steam sterilizers should not be too implicit. Accordingly in hot weather each day's supply ought to be sold as it is prepared. (4) As an additional precaution, all bottles, after being taken from the sterilizer, should be placed in warm water, and gradually cooled.

The writers point out that Flügge, Lubbert, and Weber show how it is not difficult to understand why imperfectly sterilized milk may be the cause of diarrhœa and intestinal troubles. If imperfectly sterilized milk is allowed to stand in warm rooms it will soon become a source of danger to the consumer, and it is therefore necessary to avoid this possibility by insisting that all "prepared" milk be stored in cool places.

Aliens, Dirt, and Disease.

In Great Britain there has recently arisen an outcry against the time-honored custom of allowing persons of foreign birth to land indiscriminately and settle in that country. The situation has now reached the acute phase, and so strenuously has public sentiment declared itself against the continuance of such methods that an Aliens' Bill has been introduced into the National Legislature, with the view of excluding undesirable immigrants. However, several noted Englishmen are not in favor of the passage of a law of this nature—among these being Mr. Bryce—who has asserted that Russian and Polish Jews are very much healthier than the London workers of British stock. The cudgels for the native race have been taken up by Mr. Bishop Harman, ophthalmic surgeon to Belgrave Hospital for Children, who shows that, at least so far as affections of the eye are concerned, aliens are not nearly so healthy as Londoners of the same class. The alien suffers from conjunctivitis, trachoma, and blepharitis, very much more than does the native, even from five to twelve times as much. All these diseases are contagious, some are epidemic, and others are endemic.

Mr. Harman says that the chief factor in the spread of eye affections is dirt and overcrowding. The incidence of eye affections was more than twice as heavy in the "dirty" schools as in the clean schools. Bacteriological results show that dirt is not far removed from a synonym for disease, in that dirty and ill-kept children are the hosts of more septic organisms than clean children. The examination of native and alien children, according to Mr. Harman, shows that superficial inflammations of the eye are much more frequent in the alien than in the native; also that the alien is deficient in visual acuity to a much greater extent than are the natives of London generally, or of the very poor

natives living under conditions similar to those of the poor alien. The experience gained in New York City of the eye affections of immigrants, and especially of Russian and Polish Jews, will corroborate the statements of Mr. Harman. Eye disease, trachoma in particular, is extremely rife among immigrants of this class, and the widespread prevalence of this malady in New York during last summer was wholly due to aliens suffering from the complaint getting into the city. Its contagious nature quickly spread trachoma far and wide. In self-defence it is right and just that aliens who are apt to spread disease should not be allowed to land. Moreover, in an overcrowded land—like England—strict discrimination should be exercised as to persons of foreign birth desiring to make their homes in the country.

The Feet of the Japanese Soldiers.

All military men are agreed that the feet of soldiers must be in good condition in order that they can fulfil their duties efficiently. No troops, the feet of whose members generally are not sound, are able to carry on a long campaign successfully. Napoleon, Wellington, and many other celebrated generals have insisted upon the necessity of soldiers being suitably shod. Indeed, good food and good feet are two most essential points in determining the issue of a war. The Japanese, according to all reports, is in almost every respect an ideal soldier. He is brainy, enduring, strong, and, moreover, is able to thrive on a diet which would mean almost starvation to a European, He is, in addition, patriotic to fanaticism, and, as is well known, fanatics have ever been most redoubtable fighters. But he has a weakness, and, in the opinion of Dr. Martignon, late resident physician to the French Embassy in Pekin, a fatal weakness—his feet are defective. Hi body is of iron, but his feet are of clay. The *British Medical Journal*, May 14, referring to this matter, gives an apropos quotation from Rudyard Kipling. That writer in "My Lord the Elephant," puts into the mouth of one of his characters, Mulvaney, the witty Irishman, these words, "I had a bootgall, but I was all for keepin' up wid the rig'mint and such like foolishness, so I finished up wid a hole in my heel that you cud ha' dhrew a tent-peg into. Faith, how often have I preached that to recruits since, for a warning to them to look after their feet. Our dochtor, who knew our business as well as his own, he sez to me—in the middle of the Tangi Pass it was—"That's sheer damned carelessness, sez he, how often have I told you that a marchin' man is no stronger than his feet—his feet—his feet! sez he." The feet of the Japanese are not naturally weaker or worse than the feet of other Orientals—probably better—but the authorities, in their zeal to copy accurately the equipment of European infantry, have shod their soldiers in thick heavy boots, and have in this respect overshot the mark. The Japanese have been accustomed for generations to wear sandals, paper shoes, or those made of a soft material or to go barefooted. Thus to put persons not used to having their feet restrained into heavy leather boots was an experiment not altogether in accord with the high intelligence displayed by the Japanese authorities in all other matters relating to war. The mistake may cost them dear, may even influence the result of the war.

The Census of India.

The census of India, which was taken in 1901 and which has been published recently, contains many facts of interest to the medical profession. The total population of the great British dependency was, at the time of the taking of the census, 294,361,056, next to China the most thickly populated country of the world. The gross increase of population, however, since the previous census was only 1.5 per cent. Taking India as a whole, but one-tenth of its inhabitants live in towns. There are in the Empire only 963 females to 1,000 males. There is no evidence of any serious concealment of females in the enumeration, and the difference in the proportion of the sexes must be sought in the excess of male births, which occurs in India as in Europe, and in the heavier female mortality arising from the comparative neglect of female children. Such children are unwelcome, especially where husbands are difficult to get, and they are often ill-fed, ill-clad, and neglected in sickness. Infanticide seems to be rare. Premature cohabitation and child-bearing, with unskilful midwifery, hard work among the lower classes, and other adverse conditions, enhance female mortality.

In the last twenty years there has been a striking and continued decline in the number of all afflicted persons—insane, deaf mutes, blind, and lepers in India. This must be ascribed partly to better enumeration, partly to improved sanitation and extended medical relief, partly to the severe effects of the famine and plague on the poorer sufferers. Insanity is rare in India, and Eurasians and Parsees are most affected by it. Operations for cataract mainly account for a large decline in blindness, which prevails most in hot, dry areas. The prevalence of leprosy is greatest in Benar, Assam, and Bengal, but the disease is extraordinarily local. In Western Bengal it is twice as bad as it is anywhere else, and the figures are 37 per 1,000 for males and 17 for females, as against 0.48 and 0.17 respectively for India generally. The eating of badly-cured fish does not seem to explain leprosy in Western Bengal if it does anywhere, and the areas of greatest prevalence differ as to diet, as well as in race, climate, etc. The census shows a decline of 23 per cent. in lepers since 1891, but the disease is probably more rife than figures show.

In India both birth rate and death rate are high, and the excess of the latter over the former is only about one-half of that in England. Consequently the population increases less rapidly in India. The mean age of the persons of both sexes is about twenty-six years.

The Feeding of Infants.

The need of giving to infants proper food, that is to say, mother's milk, is being continually urged. Notwithstanding that the vital importance of thus feeding babies is made the subject of discussion by medical men everywhere, women as a rule appear to be little affected by arguments and continue to feed their young children in the manner which gives the least trouble to themselves. Accordingly, the cry is heard on all sides that the civilized races are degenerating.

Sir James Crichton Browne, in the Presidential address to the British Association of Sanitary Inspectors, recently delivered by him, treated this matter from a somewhat novel standpoint. He first drew attention to the disastrous consequences to infants of their being deprived of their natural food from the maternal breast, and showed by statistics that this shirking of duties on the part of mothers was followed by most serious consequences. Figures prove that of 150,000 infants who die annually in England in the first year of life, three-

fourths have been fed artificially, and one-fourth nursed at the breast. In France the mortality of breast-fed children is 8 per cent. while that of hand-fed children is 61 per cent. The true cause of this excessive death rate among artificially nourished children, although disguised under the names of various diseases, is in the vast majority of cases malnutrition. The speaker further considered the question from the purely commercial point of view and calculated the pecuniary loss to the nation of abstaining from maternal nursing. He computed that the normal milk supply of English mothers for the year 1901, based upon the birth rate, would have been 63,000,000 gallons, and worth at one shilling per gallon, £3,150,000 ($15,750,000). As to the quantity wasted or suppressed, there are no means of accurately estimating, but it is certain, judging to the extent to which the custom of artificial feeding of infants prevails in England, that a very large proportion of the total amount of mother's milk provided was not utilized for its intended purpose. The way in which the ordinary well-to-do woman, and especially the fashionable woman, evades her duties to the child she has brought into the world, and to the nation of which she is a member, is, thinks Sir James Browne, disgraceful. He therefore, earnestly asked medical men to exert their influence and to endeavor to persuade their female patients to nurse their own children and not to evade this manifest duty upon any trivial excuse.

News of the Week.

The Medical Staff in the Isthmus.—Col. William C. Gorgas, U. S. A., chief sanitary officer on the Isthmus of Panama, together with his first assistant, Major Louis La Garde, sailed for Colon on Tuesday of this week. He has requested the appointment from civil life of 300 physicians to care for the 50,000 laborers who will be employed in the work on the canal. Dr. La Garde will be in charge of the hospital work, having his headquarters at the old French Hospital in Panama.

An American Hospital in Malta.—Mr. Henry L. Clapp of New York, for the last ten years or more a resident of Malta, has commissioned a firm of New York architects to design a hospital which he and Mrs. Clapp propose to build upon St. Julian's Hill, a suburb of Valetta in that island. In a recent letter to the architects Mr. Clapp wrote: "I want the hospital to be of a thoroughly American type—the plans to be prepared by American architects and up to date in every respect. I am the only American resident on the Maltese Island, and I desire to have this hospital an honor to the Stars and Stripes, which will float over it, and a blessing to my countrymen who may need such a refuge in a foreign land." The hospital will be for the care of acute cases only, and no patients with consumption or any incurable disease will be admitted. There will be a Washington Hall, a Lincoln Hall, a Victoria Hall and an Alexandra Hall. In the plan there will be a place for a museum building. The Nursing Sisters of the Little Company of Mary, well known in Malta, will have charge of the nursing department.

Dr. Spratling's Appointment to Bellevue.—The Municipal Civil Service Commission has decided not to recognize the appointment by the Trustees of Bellevue and allied hospitals of Dr. William P. Spratling, formerly Superintendent of Craig Colony for Epileptics at Sonyea in the Genesee Valley, as superintendent of Bellevue Hospital. His appointment from a place in the State service, *vice* Superintendent Mabon, who entered the State service, is questioned, and it is contended that he should have been subjected to a civil-service examination. The commission holds that before it can certify to Dr. Spratling's salary he must be subjected to an examination. Assistant Superintendent Michael J. Rickard was pressed as a candidate for the place and was defeated by only one vote at an animated meeting of the trustees. The trustees who voted for Dr. Spratling contend that the Municipal Civil Service Commission has no power to overrule the State Commission.

Officers of the American Surgical Association.—At the closing session of the American Surgical Association, June 17, the following officers were elected for the year 1904–1905: *President*, George Ben Johnson, Richmond, Va.; *Vice-President*, Emmett Rixford, San Francisco; *Secretary*, Dudley T. Allen, Cleveland; *Recorder*, Richard T. Hart, Philadelphia; *Treasurer*, R. S. Fowler, Brooklyn. San Francisco was chosen as the place of meeting for 1905. A resolution of respect to the memory of Dr. James S. Dunn, who died suddenly on the night of June 16, was adopted. The following were elected to fill vacancies in the membership, which is limited to 125: Drs. Harvey G. Mudd of St. Louis, Charles H. Frazier of Philadelphia, Archibald MacLaren of St. Paul, and Charles B. Porter of Boston.

The New St. Luke's Hospital in St. Louis.—The new hospital building of the St. Luke's Hospital in St. Louis was opened recently. The building occupies a plot of ground 475 x 350 feet, covering over half of a city block. It is situated on the crest of a hill in the resident section, and in one of the healthiest and most beautiful sections of the city. The buildings are on the modified pavilion plan, fireproofs and a separate building for nurses. The cost of the buildings and furnishings was $350,000, and the appointments throughout are of the most approved and complete pattern. The three operating rooms are complete in every detail, with separate chambers for sterilizing instruments and dressings, surgeon's disrobing rooms with shower and tub bath, and retiring rooms. The hospital is governed by the Episcopal denomination, and maintained by private subscription and public contributions, though it has an endowment fund of $75,000. Dr. Harvey G. Mudd is the surgeon-in-chief.

The Delaware State Medical Society.—At the annual meeting of this society, held at Lewes on June 12, Dr. Alexander Lowber of Wilmington was elected president, and Dr. John Palmer, Jr., 1900 Delaware avenue, Wilmington, secretary. The next meeting will be held in Wilmington on the second Tuesday in October, 1905.

A Curious Insurance Ruling.—An interesting decision was rendered a short time ago by a Philadelphia judge in a suit against the Metropolitan Life Insurance Company. A man took out a policy in 1889, in which was a clause providing that after two years the policy should be non-contestable except for non-payment of premiums or fraud. In 1903, the insured, who had paid all his premiums when due, was hanged for murder. The company refused to pay and the executors brought suit. After citing a line of cases bearing upon the subject, Judge Ralston said: "We consider, therefore, that upon grounds of public policy the law of Pennsylvania forbids recovery upon a policy where the insured has been executed for crime, and this whether the policy contains a clause upon the subject or not, and even if it stipulates that the company shall be liable in such a contingency. The rule for judgment is discharged. This is visiting the sins of the father upon the children with a vengeance; for of course the punishment of the dead man is not increased, the only

sufferers being his wife and children, already deprived of his support by the execution.

Smallpox in the Ohio Penitentiary.—Two cases of smallpox have broken out in the Ohio State Penitentiary at Columbus, Ohio. The Penitentiary Hospital has been quarantined.

Failure of Electrocution.—At the Ohio Penitentiary annex during the past week two miserable failures have occurred in electrocuting condemned men. Michael Shiller was given an initial shock of 1750 volts but revived, later he received 1900 volts for eight seconds; this was run down gradually to 250 volts during fifty-three seconds, after three minutes he again revived and was again exposed to the current for two minutes. Moses Johnson, the second victim, required eighteen minutes of intermittent shocks before he was pronounced dead.

Association of American Medical Colleges.—The fifteenth annual meeting of this association was held in Atlantic City, N. J., June 6, 1904. Fifty-two colleges were represented. Four colleges applied for membership and were accepted. The application of one college was not acted upon, pending further investigation. The total membership of the association is seventy colleges. The association acted favorably on the recommendation of the Special Committee to continue the visitation and inspection of all the college that are members, and the following committees were appointed to report at the next meeting: *Committee on Uniform Curriculum*, Geo. M. Kober, W. J. Means, and Parks Ritchie. *Committee on Medical Education*, Fred. C. Zapffe. This Committee to confer with similar committees from the American Medical Association, Southern Medical College Association, American Confederation of Reciprocating Examining and Licensing Medical Boards, The National Confederation of Licensing and Examining Boards, The American Institute of Homœopathy, The National Association of Eclectic Physicians and Surgeons, and the Association of Physio-Medical Physicians and Surgeons. This committee is to consider the question of medical education in all its phases, including preliminary education and entrance requirements. Papers were read by Wm. H. Wathen, Louisville; H. L. Taylor, Albany, N. Y.; Geo. M. Kober and Seneca Egbert, Philadelphia. The following officers were elected for the ensuing year: *President*, Samuel C. James, Kansas City, Mo.; *Vice-Presidents*, R. Dorsey Coale, Washington, D. C.; R. H. Whitehead Chapel Hills, N. C.; *Secretary-Treasurer*, Fred. C. Zapffe, 1764 Lexington Street, Chicago. *Judicial Council*, Wm. J. Means, Columbus, Chairman; Randolph Winslow Baltimore; H. B. Ward, Lincoln, Nebr.; Geo. M. Kober, Washington, D. C.; Thos. H. Hawkins, Denver, Colo.; Parks Ritchie, St. Paul, Minn., and John M. Dodson, Chicago. The next meeting will be held on June 5, 1905, at Portland, Ore.

The American Gastro-Enterological Association held its annual meeting at Atlantic City, June 6 and 7. A symposium on Gastric Ulcer was the chief topic of the proceedings. Harlow Brooks, New York, discussed the pathological anatomy, and W. G. MacCallum, Baltimore, the pathogenesis. Campbell Howard analyzed the post-mortem and clinical statistics of many hospitals in the United States and Canada. Symptomatology, course, complications, sequelæ, and differential diagnosis were discussed by M. Einhorn, J. Kaufmann, M. Manges, all of New York, and H. W. Bettmann of Cincinnati. Medical and surgical treatment were discussed by S. W. Lambert and J. A. Blake, both of New York; the condition of the blood and urine was discussed by T. Futcher, Baltimore, and the occurrence of gastric ulcer in children by E. G. Cutler of Boston. Other papers were read by J. C. Hemmeter, J. Friedenwald, both of Baltimore, C. D. Aaron of Detroit, F. H. Murdoch of Pittsburg, and F. B. Turck of Chicago. The following officers were elected for the coming year: *President*, S. J. Meltzer, New York; *Vice-Presidents*, F. H. Murdoch, Pittsburg; H. W. Bettmann, Cincinnati; *Secretary*, C. D. Aaron, Detroit; *Member of the Council*, W. G. Morgan, Washington. The next meeting will take place in New York during the Easter vacation.

The Basis for Medical Charges.—Judge Ryan of St. Louis recently decided that the finanical condition of a patient should not be taken into consideration by physicians in making charges for professional charges. "The character of the service, the seriousness of the complaint, the skill and time required, the result reached," he says, "are elements to be considered, but not the wealth or poverty of the patient." The decision was rendered in setting aside the verdict of the jury in the suit of Dr. M. P. Morrell of St. Louis against Dr. J. J. Lawrence of New York. Dr. Morrell came to this city and performed a surgical operation on young Lawrence, charging $30,000. The jury awarded him $12,000, but Judge Ryan deemed even this amount excessive..

To Guard British Interests at the Lisbon Congress.—In order to allay the feelings of irritation and disappointment rankling in the minds of those who attended the Madrid Congress, and to reassure these and others who may contemplate attending the Lisbon Congress, the British National Committee announces that it will "take steps to prevent or reduce to a minimum at the Lisbon meeting the annoyance, discomfort, and disappointment experienced in Madrid in regard to traveling facilities, lodging accommodation, etc." To attain this end it is purposed to have a local British Committee at Lisbon to keep in touch with the executive of the Lisbon Congress.

A Russian Red Cross Scandal.—In a despatch from St. Petersburg to the Berlin *Post*, it is stated that a Russian general lost over a million rubles through speculation in stocks, and took the money from the Red Cross Treasury. In order to avoid scandal, the Empress Dowager, who is the protectress of the Red Cross Society and a friend of the thief, reimbursed the sum. The dispatch further says that several of the nobility have also been guilty of irregularities in connection with the Red Cross management.

A Gift to the Home for Incurables.—At the recent annual meeting of the Society of the Home for Incurables, Vice-President D. O. Mills announced that a check for $25,000 had been received from Miss Emily A. Watson for the purpose of adding a story to the south pavilion. At the beginning of the year just ended there were 276 patients in the Home. Thirty were discharged and 50 died and 81 new patients were admitted during the year. There are 88 free patients, 13 life-bed patients, 37 on endowed beds, and the remainder are pay patients.

Another Medical College in New York.—It is stated in the daily papers that a medical school and a law school will be added to St. John's College, Fordham, in the Borough of the Bronx. Formal application has been made to the State Board of Regents for permission to have included in the curriculum the departments of law and medicine. The charter of the college, obtained in 1846, is that of a university, and the name of the institution will be changed from St. John's College, Fordham, to St. John's University. The trustees of Bellevue and Allied Hospitals recently purchased several lots on the grounds of

St. John's College as a site for the new Fordham Hospital, and the clinical facilities of this hospital will probably be at the disposal of the new medical school.

Carnegie Biological Laboratory Opened.—A branch of the Carnegie Institute, at Washington, was formally opened at Cold Spring Harbor, L. I., on June 11, with appropriate ceremonies. The branch is established for the purpose of carrying on the work of the institute during the summer months. The laboratory will be in charge of Dr. Charles B. Davenport, who has had charge of the biological laboratory of the Brooklyn Institute for the last ten years. The two institutions will work in harmony and will carry on their researches together. The construction and maintenance of the institute are provided for by funds from the Carnegie Institute, at Washington. The object of the new institution is to afford facilities for the study of the various branches of evolution—heredity, descent, relationships, and development of species both of animals and plants.

Reorganization of the American Red Cross.—At a recent meeting of the Red Cross Society in Washington, the trouble which has divided the members of the society into two factions was, it is hoped, satisfactorily adjusted. All of the trustees and other officers, with the exception of three, resigned and a new set was elected. Ex-Surgeon General W. K. Van Ruypen of the Navy was made president and Dr. Walter Wyman, surgeon-general of the Public Health and Marine-Hospital Service, vice-president. The appointment of a special committee was authorized to adopt resolutions in recognition of the services of Clara Barton, the former president of the society. A resolution complimentary to Miss Barton was offered at the meeting, but is was ruled out of order.

Plan to Record all Consumptives.—Dr. John H. Simon, Health Commissioner of St. Louis, is endeavoring to have all cases of consumption reported to the Board of Health, and secure to that body authority to supervise such cases. Dr. Simon's plan is to have each case recorded as soon as possible, and by the observance of certain rules, to be issued by the Health Department, obviate the dissemination of the disease. The houses will not be placarded as is done in the case of diphtheria, typhoid fever, etc., but persons sick with consumption are to be reported to the Health Department, and that body is to have a supervising control over the care of the patient.

Obituary Notes.—Dr. JOHN H. DORN of .this city died suddenly on June 17, in London, while on his way to a health resort in the south of France. He was born in Johnstown, N. Y., April 9, 1840. He enlisted at the beginning of the Civil War and was captured at the first battle of Bull Run. At the close of the war he returned to the Albany Medical College, where he had begun his medical studies. He was graduated in 1865 and began practice in New York. In 1875 he was appointed Police Surgeon, and he remained in that office until 1895.

Dr. JAMES HENRY DUNN of Minneapolis, Minn., died suddenly in St. Louis on June 16. Dr. Dunn delivered an oration before the American Surgical Association, and shortly after retired and went to his room at the Southern Hotel. Several hours afterward a chambermaid entered his room and found him dead. He appeared to be in the best of health, and had taken active part in the proceedings of the meeting, and his death was a great shock to the members. At the autopsy it was found that death was due to parenchymatous myocarditis. Dr. Dunn was fifty-five years old when he died. He was president of St. Mary's Hospital in Minneapolis, and Professor of Genitourinary Diseases in the University of Minneapolis. He was Minnesota's delegate to the International Congress at Copenhagen in 1884, and President of Minnesota State Medical Association in 1889. He was a graduate of the New York University Medical School in the class of 1878.

Dr. MICHAEL J. HUGHES, port physician of Wilmington, Del., died at Bedford Springs, Pa., on June 19. He was graduated from Jefferson Medical College in the class of 1883. He had for several years been port physician, and he was also a member of the Wilmington Board of Health.

Obituary.

NATHAN SMITH DAVIS, M.D., LL.D.

CHICAGO.

DR. N. S. DAVIS, through his life-long interest in the American Medical Association, perhaps the best-known physician in the country, died at his home in Chicago on June 16, at the ripe age of eighty-seven years. He was in good health up to within a few days of his death. He was born in Chenango County, N. Y., on January 9, 1817, and was graduated from the College of Physicians and Surgeons, Fairfield, N. Y., in 1837. He began practice in Vienna, N. Y., but soon removed to Binghamton, and in 1847 came to New York City, where he edited for a time the *Annalist*. In 1849 he received a call to the chair of physiology and pathology at Rush Medical College, Chicago, and moved to that city the latter part of August as soon as the subsidence of the cholera epidemic of that year left him free to follow his own inclination. He continued to reside in Chicago until his death.

A resolution which Dr. Davis introduced at a meeting of the Medical Society of the State of New York in 1845, calling for a national convention to discuss medical education, gave the incentive to the foundation of the American Medical Association, and for that reason and because of the intense devotion which he always showed to the organization, he was often called the "Father of the American Medical Association." He was also one of the founders of Northwestern University, the Chicago Academy of Sciences, the Chicago Historical Society, the Illinois State Microscopical Society, the Union College of Law, and the Washingtonian Home for Inebriates. His fame as a physician was by no means confined to the boundaries of Illinois, for he bore an exalted reputation in his profession throughout the entire country. In 1855 he became editor of the *Chicago Medical Journal*. In January of 1860 he started a new magazine, and called it the *Chicago Medical Examiner*, which he continued as an independent journal until 1873, when both publications were merged under the title of the *Chicago Medical Journal and Examiner*. In 1883 he was chosen editor of the *Journal of the American Medical Association*. The most important of Dr. Davis' writings is said to be a textbook on agricultural chemistry, used in district and public schools. He was also the author of a history of medical education and institutions in the United States, from the settlement of the British Provinces to 1850. He was a frequent contributor to current periodical medical literature. Dr. Davis was President of the International Medical Congress of 1887, and was Dean of the Faculty of Northwestern University, a professor in Rush Medical College, and one of the staff of Mercy Hospital for forty years.

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent.)

MEDICAL COUNCIL—ROYAL COMMISSION ON TUBERCULOSIS—CANCER AND HETEROTYPICAL MITOSIS—MEDICAL TEMPERANCE ASSOCIATION—REGISTRATION FOR BARBERS—HOSPITAL FINANCES AND APPEALS.

LONDON, June 3, 1904.

THE General Medical Council concluded its sitting on Tuesday. The session was not so long as usual, thanks chiefly to the less time demanded by its penal work, and which always suggests that the council is a very imperfect tribunal.

An inordinate amount of time was bestowed on the dispute between the council and the two Royal colleges, and more than once the discussion was animated—not to say heated. A revised course of study was submitted by the colleges, in which some slight concessions were made to the views of the council, but the members were by no means satisfied. It was reserved, however, for Sir Victor Horsley to give full expression to this feeling by moving that the proposed new courses were not "sufficient." A resolution which meant that the college should be reported to the Privy Council. The members hesitated, as usual, to take so decisive a step. But as the finances of the council are in so unsatisfactory a condition it was determined to ask the Lord President of the Privy Council to introduce a bill into Parliament to confer on the Medical Council power to establish a compulsory register for medical students and to exact a fee of £1 for registration. This was denounced on behalf of the colleges as an attempt to undermine them and at the same time minister to the propensity of the council to grasp at both power and money, and after all why should the unfortunate student be fined because the council has squandered its funds? A much more sensible suggestion would be to reduce expenses; but for this purpose it seems the only way would be to reduce the fees of the members and to restrain their talkativenes .

The most effective speech was that of the president, Sir W. Turner, who invited the councillors to reflect on what might be the consequences if every corporation held only to the letter of its ancient charter, which would not be held in every thing to suit modern methods of scientific progress.

There was another warm debate on biology, the consideration of which has once again been postponed, a resolution having been passed requesting the Education Committee to report on the question and on the advisability of including in the curriculum certain subjects without requiring them to be also included in the examinations for qualifications.

The Royal Commission on Tuberculosis issued an interim report on Tuesday. They were instructed to inquire "(1) whether the disease in animals and man is one and the same; (2) whether animals and man can be reciprocally infected with it; (3) under what conditions, if at all, the transmission of the disease from animals to man takes place, and what are the circumstances favorable or unfavorable to such transmission." So far the experiments carried o t have proved that such transmission can occur, and the commissioners have thought it their duty to make this short interim report for the reason that the result at which they have arrived, namely, that tubercle of human origin can give rise in the bovine animal to tuberculosis identical with ordinary bovine tuberculosis, seems to "show quite clearly that it would be most unwise to frame or modify legislative measures in accordance with the view that human and bovine tubercle bacilli are specifically different from each other, and that the disease caus d by the one is a wholly different thing from the disease caused by the other."

This brings us back to the view universally entertained until Koch's remarkable communication to the London Congress. The commissioners obtained about two hundred bovine animals for the purpose of their inquiry. Some were supplied with food mixed with tubercle of human origin and others were directly inoculated with human tubercle. The material for these experiments were taken from twenty different cases and from different organs. Other animals were inoculated under conditions as similar as possible with material from other bovines. The general result was that tuberculosis more or less acute, according to the circumstances of the individual case, was set up. The commissioners carefully compared the disease arising in bovines from human tubercle with that set up in the bovines by material of bovine origin. So far they found the one, both in its broad general features and in its finer histological details, to be identical with the other. Up to the present time they have failed to discover any character by which the one can be distinguished from the other. Their records contain accounts of the post-mortem examinations of bovine animals infected with tuberculous material of human origin, which might be used as typical descriptions of ordinary bovine tuberculosis.

Messrs. Farmer, Moore, and Walker's researches on malignant growths have given rise to the erroneous idea that they consider heterotypical mitosis is a sufficient explanation of the phenomena of carcinoma. But they disclaim any such notion. In their papers before the Royal Society they gave no occasion for such a conclusion, although it may have been easy enough to gather a near approach to it from the condensed abstracts that have been circulated by the press. The heterotypical mitosis in certain of the cells in malignant tumors resembles that of the sexual cells in the ovary and testicle and has been spoken of as reduced, because the number of chromasomes is no more than half of the number produced by the ordinary somatic cells. In the tissues of benign growths they do not find similar mitoses. They do not pretend to explain the relation between heterotype mitosis and the life history of carcinoma.

The British Medical Temperance Association cel brated its twenty-eighth annual meeting last week, Prof. Sims Woodhead, F.R.S.E., presiding. He said it was by no means an inactive body, but has had an important influence in strengthening the temperance cause. A lantern demonstration of colored photography and a musical entertainment followed the report and formal business, after which Mr. A. Pearce Gould gave an address in which he urged that the scientific view rather than the social should be adopted by medical men in their intercourse with patients.

Registration being the fashionable cure for all evils, it is proposed on no less authority than the Medical Officer of Health for the city to register barbers. Among other things, those registered would have to discard powder puffs for pulverizers, have all shelves of glass, refuse to serve a customer apparently suffering from any skin or hair disease, keep razors and combs in a 5-per-cent. solution of sodii carb., boil all curlers and tongs for ten minutes and so on. Regular customers are advised to provide their own requisites. Perhaps the barbers will next agitate for diplomas.

Hospital festivals and demands for money have been numerous during the week. On Tuesday His Royal Highness the Duke of Connaught presided over the annual festival of King's College Hospital. He spoke of the interest of the Queen in hospitals, of the work of Lord Lister at King's, and of the approaching removal to Denmark Hill. Subscriptions amounting to £2,160 were announced. Last evening there was a meeting in the new locality in aid of the project, when it was announced that 500 guineas had been voted to the building fund by the Grand Lodge of English Freemasons.

A great fancy ball was held on Tuesday evening at the Albert Hall on behalf of Charing Cross Hospital. The program was not concluded until the early hours of Wednesday morning.

Lord Glenesk presided at the annual meeting of the West London Hospital and referred to the lost forceps' case. He pointed out the necessity of operating in a hurry on the patient's admission *in extremis*, and further that it had to be hastily concluded, as the patient was rapidly sinking. He was glad the case had been reported to the coroner, so that poor patients could always feel they had every protection. He hoped good might come out of the evil, and that such events should become impossible. The report showed a total expenditure of £11,330 and income of only £10,216.

Yesterday, at the annual meeting of the North Eastern Children's Hospital, it was stated that without immediate help most of the wards must be closed; £9,000 had been spent on the enlargement on the prospect of increased subscriptions. But these have not come in. It seems another instance of reckless building on the chance of a public response to a cry for help. But what a time is this to indulge in such hopes!

OUR LETTER FROM THE PHILIPPINES.

(From Our Special Correspondent.)

SANITARY PROBLEMS IN THE PHILIPPINES—OBSTACLES TO HYGIENIC REFORMS—HOW TO OVERCOME NATIVE PREJUDICE AND IGNORANCE—DIFFICULTIES OF COMMUNICATION—DIVERSITY OF RACES AND TONGUES—NEED OF A COMMON LANGUAGE.

MANILA, May 4, 1904.

WITH a more extended acquaintance with the Filipino, his beliefs, customs and surroundings, one is tempted to forecast the future and estimate the sanitary progress which it may fairly be anticipated a continuance of the American policy will bring to these islands. Under Spanish rule, health matters were largely neglected, sanitary organization was defective and the little that existed served chiefly for purposes of "graft" and corruption. Some few sani-

tary regulations held a place in the local ordinances, but were rarely enforced except as a means of extortion by the unscrupulous. In the great majority of communities, no laws having to do with the public health existed, and the individual pursued his way from the cradle to the grave untroubled by any responsibilities affecting the health of his fellows. In the smaller villages and among the less civilized tribes the insanitary conditions of primitive mankind were the rule. These sanitary defects were not, however, fairly chargeable to the Filipino, for the latter took the Spaniard as his model in all things, and was not aware that the Spanish nation, as a whole, in matters sanitary, is regarded as least advanced among the civilized peoples of the world. The sanitation introduced by the Americans was therefore a new thing to the Filipino. It was unfortunately not introduced gradually, but the appearance in the islands, in rapid sequence, of the infections of bubonic plague and Asiatic cholera caused its measures to be applied in their greatest stringency broadcast over the archipelago and in places and among persons in whom there was not the faintest conception of what constituted the elementary rules of a hygienic mode of life. The necessary sanitary precautions against epidemic outbreaks of the above-mentioned diseases were such as would have provoked considerable opposition from an even more intelligent population, and it was therefore not strange that the Filipino—suddenly surrounded by irksome restrictions of a nature previously unknown and whose purpose was little understood, instituted by persons whom he had been taught by the Spaniards to distrust and with whom he had but recently been at war—should have harbored resentment against sanitary control over his life and opposed it by every means in his power. The measures instituted meant interference with business and social communication, financial loss, interference with the privacy of the home and the removal and treatment of the sick and the disposal of the dead in a manner which was opposed to personal preference and offensive to religious teaching. Under the circumstances, on looking back over the whole situation, the wonder is not so much that the Filipino often nullified measures intended purely for his welfare, but that his opposition to these unknown measures was not more general and pronounced. The American is too apt to regard the situation here from his own standpoint, instead of assuming that which tradition, race, and environment have forced upon the Filipino, and to argue from the false hypothesis that the latter has had the benefit of equal educational and civilizing facilities with himself and reasons from a sound knowledge with the clear perception and unbiased mind of the Anglo-Saxon. On the contrary, the great majority of Filipinos live in small hamlets under the most primitive conditions, cut off from the world by lack of facilities for communication, and with mentalities dwarfed by environment and lack of opportunity. Too much cannot be expected under such conditions any more than that in the United States the schoolboy twelve or fourteen years of age cannot be expected to perform a man's part or possess the discretion of an adult. Patience, charity, forbearance, and a desire to understand the native attitude are therefore urgently demanded in the prosecution of any sanitary purpose. On the whole, the Filipinos are a very tractable people and submissive to proper authority. Like any other class the world over, however, they view the innovation and the unknown with a suspicion which disappears only with closer acquaintance and a more thorough knowledge. Declaration not only of the purpose but the reasons therefor and the ends to be obtained should therefore be fully set forth. It would seem that perhaps at the outset this matter was disregarded, and the effort made to enforce new laws the purposes of which were not understood by the natives, with the result that there was not, in many cases, any effort for coöperation by them and the passive opposition frequently aroused, was sufficient for the complete nullification of the measures intended for their benefit. A prime essential for sanitary success therefore consists in securing the confidence of the Filipinos, making them understand that the authorities are working for their welfare, and in allaying the popular impression that sanitary work is carefully devised for the sole purpose of their annoyance. It must not be forgotten that the mass of the people are absolutely fatalistic and disinclined to help themselves, believing that their lives are so regulated by the Divine Will as to render human effort unavailing. This belief is not confined to the pagan tribes and the Mohammedans of the south, but is very strongly entertained by even the higher classes of the Christian tribes as a result of the mediæval type of Catholicism inculcated by the Spanish friars, jealous of medical science and anxious to have it thought that the sole power over health and disease reposed in the Church. Such a belief was a powerful aid in their control of the minds of the people, and the whole attitude of the friars toward preventive medicine was secret opposition and open contempt. The kind of religion taught by them could not stand the light of modern education and was not at all of a kind which would receive the approval of American Catholics. Nevertheless, this attitude of the Church has left its impression and must be reckoned with in the prosecution of sanitary work. First and foremost, the Spanish friars should be replaced by American priests. With very few exceptions, the former neither understand us nor our institutions, dislike our purposes and methods and regard the collapse of their power as the result of American sovereignty. They cannot be reconstructed and should therefore be removed. With American priests largely installed in their places, the unquestioned power of the Church over the people should be recognized and utilized and the hearty coöperation of the American-bred priests would be gladly granted. The priest is the power in the small community, and his influence determines the attitude of his parishioners. The church should thus be worked through literature circulated through its medium, and in the case of all important measures the support of subordinate priests enjoined by the local insular hierarchy. This support will be even more readily secured because of the recent native defection from the Catholic Church, both resulting bodies of which are anxious to secure the governmental favor. The new independent Catholic church numbers its adherents chiefly among the poorer classes, whom it is most important to reach in a sanitary way and probably controls half of the Christian natives. It will probably not be able to maintain its existence long, but for the next few years it should be reckoned with and utilized. The seceding native priests of the new church will not be individually inclined to support sanitary measures strongly, but their attitude can be directed by their superiors, who are eager for recognition. The Protestant churches are numerically unimportant, but their heads are energetic Americans, whose influence will be valuable and will be given without reservation to any worthy purpose. Every effort should be made to inculcate the knowledge among the people that disease is largely preventable, and that epidemics are not the sign of divine wrath for dereliction in church duties. Just so long as disease is regarded as inevitable and retribution for sin, the necessary measures for its prevention will not be taken.

Another practical difficulty in the way of sanitary work is found in the inadequacy of communication throughout the islands. Here all roads (and steamer lines) lead to Manila instead of Rome, and it may often be necessary to make a journey to and from Manila, lasting a week or more, in going from one place to another a hundred miles distant. There is but one short line of railroad in the islands. There are but few roads, the majority of those are bad, and all of them are practically impassable during the five or six months of the rainy season. During this season whole districts can scarcely be entered, roads are flooded and washed out, and unbridged watercourses become uncrossable, roaring torrents. The chief means of communication is found in the small interisland steamers. These dodge about among the islands, picking up cargo. Except in a few instances, they have no fixed day of sailing, and scarcely any of them pretend to make their runs on any schedule time. The majority of them are owned by large trading companies and are operated primarily in their business, little attention being paid to the general carrying trade for other parties, and the dates of sailing and ports of destination being altered without notice. These vessels trade to the chief shipping points, whence further travel or shipments must be made by small native sailboat or canoe. In addition, it is not infrequently required that the person to whom shipment is made must see to the removal from the vessel, almost always anchored far from shore in the absence of wharves, of the articles shipped. Should the consignee be absent and have failed to secure some one to act for him, the goods sent him are invariably brought back to Manila. In addition, there are practically no sheltered ports on the entire Pacific side of the Archipelago, and during the monsoon from November to June almost no landings can be made on that coast through the rough surf. On the other hand, the coast washed by the China sea has but few harbors in which landing can be made during the typhoon season from June to November, and the best that can be done during that period is to make landing at the nearest port and secure such transportation over the difficult roads as opportunity offers. The interior is penetrated by canoes, which go up the shallow but often long rivers, except in the season of flood. The interior of Luzon is penetrated for several hundred miles in this way, but transportation of this sort is naturally slow and primitive. Finally, there are many large interior sections which can be reached only on foot or horseback, and at least two provinces of Luzon to which access is had only on foot and burdens are carried in and out by bearers. Thus to go from Nueva Vizcaya province to the end of the railroad, 120 miles, takes a week—from the end of the railroad to Manila, 140 miles, takes seven

hours. Some of the smaller islands are even yet visited by steamers but twice a year, in spite of the effort being made to bring all parts of the Archipelago into better communication with the capital. Mail service naturally depends on facility of communication, and is in many places infrequent and irregular. Telegraphic communication, through the military telegraph lines, is now far better than it ever was before, but a large number of districts are not penetrated. Further, as the lines were intended to be temporary only, they are constantly being broken and communication interrupted. Outside Manila there is no telephone service. Under such conditions, sanitary work can be prosecuted only with difficulty. Disease may assume an epidemic form before report of its existence has reached the authorities, emergency orders are delayed by infrequent mails or broken telegraph lines, and employees may be held up for weeks awaiting transportation while unchecked pestilence rages. Supplies sent out spoil en route, are misdelivered or are returned to the sender as a result of the absence of the consignee or the ignorance or indifference of the carrier. Under such circumstances, the best laid sanitary plans may at any time be nullified. This contingency is only to be avoided by the creation of better means of communication, a satisfactory condition of which is, from present indications, at least a generation off. Much depends in this respect upon the influx of capital and the commercial development of the country, and the insular laws are at present of such character as not to attract capital to the islands.

Another factor interfering with sanitary work is the great dissimilarity of peoples, customs, and languages throughout the islands. It is said that no less than eighty-one native languages and dialects are spoken in the Archipelago, and for circulation in the island of Luzon alone the Board of Health lately printed circulars in eleven languages. The ethnological field presented in the Philippines is probably the richest for any place of equal area the world over. The tribal system prevails, and even those of the same racial stock are hostile to each other and many were until lately at war. The savage tribes wage constant feuds with each other, and between Christian Filipino and Mohammedan Moro there is undying enmity. Predatory bands and tribes of head-hunting savages render certain districts unsafe for small American parties, and in Mindanao there are still places where a body of a hundred white men would not dare to venture. The Americans have already explored the islands more than the Spaniards did in three centuries; yet there are still many primitive savages who have never seen a white man. One tribe cannot understand another's language and is unacquainted with affairs outside its own territory—frequently persons in all tribes will be found who have never been five miles from the place where they were born. Even within the same tribe, the inhabitants of two neighboring towns regard each other as foreigners. The diversity in appearance, customs, language, and religion between such main types as the Filipino Negrito, Moro, and Igorrote is complete, and the minor types have almost as little in common with each other. In spite of the efforts of the anti-imperialists to create such a political entity, there is no such thing as a Filipino nation, nor can there ever be. Differences are too great to fuse them all into a single national type. The various units will undoubtedly come closer together, and some, like the negrito, will disappear before a higher civilization, but highways, railroads, and telegraphs will never bridge the gulf which race, religion, and custom has created between the various tribes. A common language, as a means of intercommunication, is much to be desired. This will naturally be English, as none of the native languages possess any literature or is in sufficiently general use to warrant its supplanting the others. This general adoption of a single language is, however, far in the future. English is being generally taught in the schools, but is practically in the position of a dead language, as it is not used in everyday life, and will rarely if ever be employed by a large part of those to whom it is now being taught.

A QUESTION OF PRIORITY.

To the Editor of the Medical Record:

Sir: Dr. D. Tod Gilliam says, in the Medical Record of May 14, 1904, in regard to uterine suspension by the round ligaments, as recently advised by Bardescu (*Centralblatt für Gynäkologie*: "I simply wish to claim for this country that which is due and of which she is often deprived. The credit for original work and investigation." As laudable as Dr. Gilliam's patriotism is, so defective is his claim for priority in this method. A glance at the *Centralblatt für Chirurgie* for August 21, 1897 ("Eine neue Methode der Hysteropexie"), shows that I practised uterine suspension by means of round ligaments just two years and seven months before Dr. Gilliam published his account of the procedure.

Carl Beck, M.D.

VACATION FOR THE DOCTOR.

To the Editor of the Medical Record:

Sir: While many may say there is no vacation for the worker in the medical profession, and least of all for the young practitioner, and while the recent graduate may, of all others, be least able to pay for an outing, I think that not only does the younger man need a change and relaxation from the responsibilities, but the middle-aged doctor as well will be enabled to keep his arteries softer if he will go away for a couple of months a year. I desire to describe a plan whereby one may enjoy a summer holiday at the cost which has more than once been presented to me in the following words after having taken such trips, "You don't owe me a cent, and you can come aboard anytime you like, and stay as long as you're a mind to."

The coasting trade of the United States upon the seaboard and great lakes requires many hundreds of schooners in its service, and it is upon these vessels that veritable yachting cruises may be taken for the asking, and at little or no expense to the voyager. The captains, who are usually part owners of the vessels in which they sail, will be found a most approachable set of men. While a letter of introduction from a ship brokerage firm may be useful in obtaining the desired end, these keen observers of human nature, after but a few moments of conversation, will be found willing to take the inquirer into the family groups of their floating homes without more ado. Having made a number of cruises under such circumstances as have been related, varying from a few days' run down the coast to trips into "deep water" lasting over months of time, the statement of the ease with which a cruise is arranged for may be accepted. The welcome one receives is the best aboard, a room in the cabin, a plentiful supply of good, plain food; fresh, cool sea-air to breathe, and sunshine, with a slattening sail in a calm or the rush of waters in a strong breeze to lull one to sleep at night. The associations are with a class of men from whom one can learn many and strange things in the sailorman's art, whose chief characteristic is resourcefulness. To see an uncouth, long-legged, and loosely-jointed mate aboard a "down-easter" con his logarithms after taking a "sight" is enough to make a senior collegiate thoughtful. I have known some of these men able habitually to come within a few hundred yards in their calculations of the exact position of their vessels, and have known some smart United States Naval officers to be twenty-seven miles in error when approaching our coast.

To be driven past Cape Hatteras in a gale of wind while aboard a two-masted schooner riding under a double-reefed foresail, may make it difficult for one to maintain his equilibrium of body, but it will aid him in securing the proper balance of his importance among his fellows.

Frederic Griffith, M.D.

49 East Sixty-fourth Street.

THE LOCAL USE OF QUININE IN HAY-FEVER.

To the Editor of the Medical Record:

Sir: So many remedies have from time to time been proposed for the relief of hay-fever, that subjects of this peculiar malady have become very skeptical as to their value; and very naturally so, for they all have one serious drawback—the uncertainty of their action.

The writer offers a method of using quinine locally in typical cases of hay-fever, which has proven remarkably successful in his hands. The treatment consists of the employment of a saturated solution of the quinine sulphate in sterilized water, as a nasal spray, and the application to the mucous membrane of the nares of an ointment consisting of quinine and vaselin in the proportion of thirty grains to the ounce, the applications being made every four to six hours. After trying various unguents and combinations, I have found simple vaselin to be the best. The white vaselin is not suitable, nor is the liquid vaselin. Lanoline is an ideal base, but is too offensive to the sense of smell. The use of the spray alone will not suffice, but should be used as an adjunct to the ointment. Spraying the nares will at once stop all symptoms of coryza, but the effect will not be maintained long unless followed by the thorough application of the ointment. This may account for the failure of this treatment as first suggested by Helmholtz, who employed only the spray. The application of the ointment should be made at least every six hours, and it may be necessary to repeat it every four hours. An application at bed time, and at two or three o'clock in the morning, will prevent all symptoms through the night. Two or three applications of the spray should be made in the twenty-four hours, at the times when the patient has found the irritation to be at the maximum

degree of intensity. In respect to the mode of using the ointment, the little finger is the most convenient applicator.

As far as the effects of this simple remedy have been observed, the results are as follows: Used according to the foregoing suggestions, the symptoms of coryza are immediately removed, nor will they return as long as the treatment is continued. The usual accompanying irritation of the conjunctivæ of the Eustachian tubes and palate quickly subsides. Opportunities have not been had so far to test this treatment in irregular types of the disease, or to estimate how far these results may be modified by individual peculiarities, but, so far as its effects have been noted, it seems fair to conclude that hay-fever subjects will find this a remedy of actual value, and that it will promptly and completely relieve a large proportion of these cases.

HENRY D. FULTON, M.D.

The Boston Medical and Surgical Journal, June 16, 1904.

Human Slavery as a Prevention of Pulmonary Consumption.—Thomas G. Mays draws very interesting comparisons between the state of health of the negroes when in slavery over forty years ago and that at the present time. There has been a tremendous increase of consumption and insanity in this race. This increase is due to the heavy economic and industrial burdens which were suddenly placed on their shoulders. They had neither the wisdom, mental strength, nor organized constitution to withstand this strain. This change in the race is due also to improvidence of living, to poor and improperly prepared food, to ignorance of the laws of physiology, to bad hygienic surroundings, to overcrowding, laziness, and the lack of persistent employment, to improper care and nursing when ill, to dissipation of all sorts, to lack of self-restraint, to alcoholism and other vices. The writer believes that efforts of prevention should be made which comprise the inculcation of sound principles of hygiene; the eating of wholesome and properly prepared food; the wearing of suitable apparel; the avoidance of damp and overcrowded dwellings; the abstinence from nerve-strain and overwork; the shunning of strong drink and other vices; the encouragement of useful labor and training in physical development; the supervision of proper convalescence from what to them seems a trivial cold or cough. The writer thinks it would be well to inaugurate a campaign of education by means of a charitable organization. A city could be divided into sections and canvassed by physicians whose duty it would be to teach these people how to live properly and to care for them in illness.

Journal of the American Medical Association, June 18, 1904.

Notes on Curettage.—A. P. Stoner says that this operation has become such a common practice that there are few practitioners who will not attempt the operation. He believes, however, that comparatively few surgeons become skilled in the use of the curette. Faulty technic is often manifested in operations on cases of simple endometritis. Then, again, cases for curettage are not always properly selected, in either of which case the patient receives little or no benefit; indeed, may become much worse. The uterus should be first outlined bimanually, and before the curetting is begun, the uterine cavity should be carefully explored with a dull wire curette. Then with the image of the uterus, and especially its cavity in mind, every part of its surface is systematically scraped with a thin sharp curette, the cornua being separately treated with the smallest sized instrument. The cavity is then washed with sterile water, and no packing used except in septic cases; a little loose iodoform gauze may be left in the vagina, which should be changed twice daily. Practically the only danger arising from the operation is that of infection. This can usually be avoided by the practice of scrupulous cleanliness. Indeed, the preparations for curettage should equal those for vaginal section. Infection following perforation of the uterus by the curette appears to be a rare occurrence. The peritoneum is able to take care of a great deal of toxic material, so long as it remains unimpaired, by handling or prolonged contact with the atmosphere.

The Prophylaxis of Fourth-of-July Tetanus.—In a special article on the "Prophylaxis and Treatment of Fourth-of-July Tetanus," the writer says that the abolition of blank cartridges and giant crackers would have reduced the number of deaths last year to less than twenty, and this is probably true of all other years. Display fireworks, such as Roman candles and rockets, caused but few tetanus infections, and, so far as we could learn, there were none from paper caps, torpedoes, and the small firecrackers. Surely these harmless forms of explosives ought to be sufficient for the entertainment of the children, and for "instilling patriotism" of at least equal value with the toy pistol and the cannon cracker Blank-cartridge wounds form as deceptive a class of wounds as can be imagined. Usually they present simply a rather clean-cut perforation in the skin, about which are imbedded many powder grains, for the wound is usually produced with the muzzle of the pistol but a few inches away from the skin. This is not a serious appearing wound, and if the boy's parents are not familiar with the danger he runs from tetanus they are likely to think that a simple dressing is all that he needs. And even if he is taken to a physician, too often the same opinion is expressed. The surgical treatment of the wound must be most thorough. Merely opening the wound and picking out the wads, even if followed by drainage, is evidently inadequate; and if we take into account that tetanus spores, even in the test-tube, are not killed by 5 per cent. of carbolic acid in ten hours, it is evident that no amount of washing of the wound with antiseptics will assure safety from tetanus infection. Safety demands that every part into which dirt from the surface can have been blown be cleaned out, and so packed that air can enter and wound secretions escape. This requires anæsthesia and careful dissection. The greatest difficulty in most cases will probably lie in the objections of the parents of the boy, and this must be met with instruction as to the dangers and the necessities of the situation. The prophylactic administration of tetanus antitoxin is entitled to much serious consideration. Whatever may be said concerning the treatment of advanced tetanus by antitoxin, there is no room for doubt that as a preventive it is most efficient. We now possess numerous instances of its unquestionable value in checking epidemics of tetanus in hospitals and maternities. We have been unable to learn of a single instance in which a person who had been given antitoxin soon after receiving a suspicious wound has developed tetanus. On the other hand, we have not learned of any harmful results from its injection into persons not infected with tetanus. It therefore seems safe to assume that a person who receives a prophylactic injection of tetanus antitoxin will be protected against tetanus, and will not be injured by the procedure.

Medical News, June 18, 1904.

Vesical Retention of Urine.—Fred C. Valentine and Terry M. Townsend summarize this paper as follows: When danger to life is not imminent, the domestic methods ordinarily employed may relieve the vesical retention, provided no mechanical obstacle exists. Diuretics, diluents, and antispasmodics are of no use in vesical retention of urine. Opiates and general anæsthesia are useful only under certain circumstances. Capital surgical intervention may be necessary to cure the basic condition, but the urgent symptoms can, in most instances, be relieved without life-endangering procedures. Even the youngest general practitioner can carry every case of vesical retention of urine to a successful issue. The cause of the retention must in each case be ascertainedt Only most exceptionally does a case present which cannoe be relieved by minor procedures. No bladder should be suddenly entirely emptied because of the danger of hemorrhage *ex vacuo*.

The Danger of the Use of Opium in Infancy.—T. D. Crothers states that the physiological action of opium and its alkaloid are more striking in infancy and childhood, than in later life. The organism is more unstable at this time, as well as less resistant. The sedative action of opium is that of palsy. The higher the organism, the more pronounced the effect from smaller doses. It is impossible to tell what organic changes may follow from the chemical and physiological action of any form of opium. It is hard to decide, when it is given in infancy, whether its effects are transient or whether each dose does not create a demand for its further use. In cases in which the effects of the drug are rapid and pleasing, the demand for it is pathological and an ominous symptom of the danger of its use. Nursing children may be quieted by opium taken by the mother. Children have been permanently injured in this way. Continuous sedation or palsy of the sensory centers in early life is never repaired. The writer gives instances showing the great injury done to children by this drug. Among its effects are nervous dyspepsia, beginning soon after puberty and continuing till some form of alcohol or opium is used. Early and profound exhaustion from overwork or excitement, low vitality and feeble, nervous resistance are natural sequels of its use. Defects and degeneracies appearing in early manhood suggest the same cause. The writer believes that the magnitude of this danger is not at present recognized. Too much caution cannot be given against the use of narcotics in infancy. Opium is probably among the most dangerous of these drugs, because it is so easy to obtain, and its effects are apparently so simple.

Water Anæsthesia in Surgery, and Its Suggestions in Medicine.—Joseph Clements describes two cases illustrating the effects of the injection of distilled water. In one case five hemorrhoids were injected with the water, emptied, clamped, tied, and cut away. The operation took about fifteen minutes, and the patient returned home at once after the operation. In another case two fistulæ were opened and scraped, one after the injection of water, and the other without water injection. In the last process the pain was intense. The writer describes the process as follows: The water enters the interspaces of the tissues and fills them; the pressure of the distention causes rapid osmosis into the intracellular interspaces which are between the granular appearing substance, the protoplasm, temporarily suspending intracellular respiration. This, like the heart-beat, is incessant, and when it is stopped, local "death" is caused for the time being. The nerve centers are paralyzed and no afferent impulse is sent, and no response arises in the central ganglion, and pain is consequently impossible. There is just as much of "curative" or other "property" in distilled water as in solutions of cocaine or any drug. In other words, there is none whatever. The "property," the therapeutic or whatever action arises, is protoplasmic. Upon the fact and principle of protoplasmic activity are to be interpreted all organic phenomena.

New York Medical Journal, June 18, 1904.

Labor Complicated by a Fibroid and Ruptured Uterus.—The patient of E. T. Hargrave was a negress of thirty-nine years who had had nine previous normal confinements. When summoned to her he found that she had had about one hour previously a sudden sharp pain in the right side, and when first seen was in collapse. Forceps delivery was tried, but could not be done, and podalic version was attempted. The introduction of the hand into the uterus showed a large tear in the right side of the fundus, through which loops of bowel could be felt. A fibroid was also detected. Removal to hospital was advised and rallying measures at once instituted, but the patient soon died. The author believes that the main causes of rupture were ergot (given before his arrival by an ignorant nurse), the presence of the fibroid, and an unusually large fœtus.

A Case of Splenomyelogenous Leukæmia.—C. M. Ross reports the case, his patient being a man aged thirty-four years. His symptoms began with œdema of the feet and legs, more marked at night, and with epigastric distress. These continued for ten weeks when he sought admission to the hospital. Blood examinations enabled a definite diagnosis to be made. After a week's stay in the hospital without improvement, he went away and died six days later after a condition lasting twenty-four hours, during which he became wildly delirious, refused all nourishment, and finally passed into coma with suppression of urine and abolition of superficial and deep reflexes. The noteworthy points of the case were: (1) Absence of any etiological factor; (2) absence of constitutional symptoms until splenic enlargement caused by pressure, œdema of the feet, gastric trouble, and dyspnœa; and (3) the typical picture shown by the blood, the white cells consisting largely of myelocytes numbering almost one-fourth as many as the red cells with the comparatively small diminution in red cells and hæmoglobin. No malarial parasites were found.

Appendicular Abscess with Fish Bone in the Appendix. Operation; Recovery.—The case is reported by W. P. McIntosh. His patient was a man of fifty-four years with the usual symptoms of appendicitis. He was not operated on till about three weeks after his initial symptoms, which underwent several remissions. The incision was made high up and rather long. On opening the abdomen considerable foul-smelling pus escaped. The appendix was above and behind the cæcum and was imbedded in the abscess wall. It was long and much thickened, and was perforated about the middle. The examining finger came in contact with a small hard substance about 4 cm. in length, lying across the appendix. The parts were strongly adherent to the intestines, and were bound down by adhesions. The appendix was surrounded by inflamed mesentery, the whole forming a large granular mass. The abdomen was packed around with iodoform gauze and the mass dissected out. The foreign body proved to be a fish bone, about one inch and a half long, and about the thickness of an ordinary silver probe. The appendix with adherent omentum was about five inches long and two inches in diameter. Recovery was uneventful.

American Medicine, June 18, 1904.

The Antiseptic Treatment of Smallpox.—Samuel M Wilson calls attention to the excellent results following the daily use of the scrubbaths. When it is used thoroughly before the primary papules develop, it appears to prevent vesiculation. When too late for that, it does away, to a great extent, with the repulsive appearance and foul odor characteristic of patients who do not have this treatment. If vesiculation has begun before the patient is seen, the summits of the vesicles must be punctured, compresses of full strength of hydrogen-dioxide solution applied, and these followed by a mask wet with some antiseptic. A solution of mercuric chloride—1 to 1,500—gives good results. The application of the dioxide followed by the mask may be used several times daily, if desired, and appears to add to the patient's comfort as well as promoting desquamation. Cases treated in this way have had only a few faint traces of scars, although the vesicles were large and numerous. In several cases the scrub bath with toilet soap has left the patient with only a few perceptible scars. The disease was also of very short duration.

Strangulated Femoral Hernia Containing the Vermiform Appendix.—Emery Marvel reports this case. The patient was a woman of sixty-eight years. The patient was operated on for incarcerated femoral hernia. After the bowel had been replaced in the abdomen, the finger was inserted through the femoral ring into the abdomen, where the vermiform appendix was recognized and brought out. It was folded upon the cæcum and constricted at a level with the cæcal constriction produced by the incarceration of the ring. The appendix was about seven inches long, enlarged at the tip, with a foreign substance in the lumen. The mesoappendix, as well as the mesocæcum, was very much elongated, and allowed of the appendix being easily brought out through the femoral canal. The appendix was dissected out, amputated, stump invaginated, and cæcum replaced again. Union was by first intention, and the patient left the hospital on the thirteenth day. The author notes that the aged may, and most often do, recover and repair with favorable comparison to the young.

The Lancet, June 11, 1904.

Ptomain Poisoning Followed by Desquamation.—Percy T. Goodman reports being called in the early morning to a family of seven persons who had all partaken of a fish supper on the previous evening. They were in a state of collapse, with pallid faces, clammy perspiration, and cold extremities, and were complaining of severe abdominal pain and vomiting. In two cases diarrhœa was present with very offensive stools. There was no urticaria or rash of any description. None of the family had any rise of temperature or sore throat. Warmth was applied to the extremities and a purgative was given followed by stimulants (ammonia and ether). All the patients recovered. Ten days later the mother brought one of her boys for examination of the hands and feet from which the skin was coming off, chiefly on the palmar surface, in large flakes. The mother also had some slight desquamation on the forearms. The other children, whose ages ranged between seven and sixteen years, had the same desquamation on the palms of the hands and the soles of the feet. The father alone was not affected in this manner.

Sequel to a Case of Inoperable Cancer Treated by Oophorectomy.—Walter Edmunds recalls a case of scirrhus of the breast, reported in *The Lancet* of March 29, 1902, in which symptoms of intrathoracic growth appeared five years after amputation. There was also a recurrence in the remaining breast. Oophorectomy and thyroid feeding were resorted to, with the result that at the time of the report, a year after the operation, the patient was much better. The tumor in the breast and axillary glands had almost disappeared and the dyspnœa, too, had nearly gone. The further history of the case is that nine months later the tumor in the breast had somewhat increased and was commencing to involve the skin: the dyspnœa, too, was somewhat worse. Three months later the skin over the tumor had ulcerated, and on this account it was thought advisable to amputate the breast. The patient died from heart failure while under the anæsthetic. At the post-mortem examination a mass of secondary growth was found at the bifurcation of the trachea involving the roots of the lungs. Although the oophorectomy did not save the patient's life it produced for a time great benefit; the tumor in the remaining breast almost disappeared, while the small growth behind the ear did completely disappear; the symptoms due to the intrathoracic growth were also greatly relieved.

British Medical Journal, June 11, 1904.

First Manifestation of Heart Symptoms about the Age of Forty.—John C. Thorowgood recalls the death of Dr. Thomas Arnold at Rugby. Dr. Arnold was forty-six years old at this time and had always enjoyed active muscular exercise. He retired in perfect health one night, and early next morning died in his first attack of angina pectoris. Necropsy disclosed the presence of but one coronary artery. It was of unusually small caliber, and

very slightly atheromatous. The walls of the heart were thin, and a few atheromatous patches were found on the aorta. This one small coronary artery had kept the heart going until the age of forty was well passed by.

A Bacteriological Inquiry into the Sterilization of Hands.—J. Rupert Collins reviews certain experiments and believes that they point to, if they do not justify, the following conclusions: The nail-brush used should be either boiled before use, or better still, kept always in an antiseptic solution. Vigorous scrubbing is required for at least five minutes. The water should be as hot as can be comfortably born. Chemical antiseptics of efficient strength should be used for cleansing the skin, and it is preferable that they should be used in the primary washing as well as in the final soaking. With sufficient time and care sterilization is not impossible. The mode of preparing the skin of the patient for operation will be similar to that found best for sterilizing the hands of the surgeon, though probably less friction will be required.

Pregnancy after Removal of Both Ovaries for Dermoid Tumor.—W. A. Meredith reports the history of this case. The patient was a woman of thirty-five, and recently married. The last menstrual period had terminated seven weeks before, and for eight weeks the patient had been troubled by nausea, and believed herself to be pregnant. Examination revealed the presence of double ovarian cystoma, probably dermoids. Early pregnancy was also suspected. The tumors were entirely removed and were found to be typical examples of dermoid growth. On the third day after operation, uterine hemorrhage began, and after persisting for forty-eight hours, culminated in the expulsion of a vesicular mole. Some months later menstruation began, and after nearly a year normal "periods" were established. After about a year longer, the patient began to be troubled with nausea, and at the end of the fifth month she began to feel movements at intervals. In another month the patient had a fall, followed by a miscarriage. The case illustrates the possibility of pregnancy after double ovariotomy for advanced dermoid disease under circumstances admitting of no doubt as to the complete extirpation of both ovaries.

Further Observations on the Therapeutic Value of Radium and Thorium.—J. M. H. MacLeod concludes, in regard to the therapeutic value of radium bromide, that its chief utility is in the treatment of rodent ulcer, and in the case of small rodent ulcers it acts almost like a charm. In rodent ulcers of a diameter larger than a shilling, treatment by the *x*-rays is more practical, as the whole of the ulcer can be exposed at once. In some cases of rodent ulcer which have been subjected to a long series of exposure to the *x*-rays, these rays seem to lose their effect, and the healing process becomes stationary. Radium may then be used with advantage, and the healing again stimulated. The writer believes that radium is of little value in regard to epithelioma. In the case of cancer of the uterus, further experience is necessary before any definite statement can be made. In lupus vulgaris, radium causes the disappearance of the granuloma and a replacement of it by healthy scar tissue, but this treatment is practical only in very small lesions. It is a useful adjuvant to the Finsen light and *x*-rays, as it can be applied to positions which are difficult to get at. In lupus erythematosus its value seems to be negligible. The results of the use of thorium do not appear to be at all encouraging.

Deutsche medizinische Wochenschrift, June 4, 1904.

Unilateral Nystagmus.—E. H. Oppenheimer reports an undoubted instance of this rare condition in an otherwise healthy child of fifteen months. A horizontal oscillatory nystagmus was present in the right eye while the left was perfectly normal and unaffected. He believes that it was purely optical in nature and due to a hypertropia. Treatment by atropine instillations in the normal eye was kept up for some weeks but without any visible effect.

Demineralization and Tuberculosis.—F. Steinitz and R. Weigert have made a series of practical experiments with a view of determining whether this theory holds good. The latter was first promulgated by the French writers, who claimed that a reduction in the inorganic constituents of the body, and hypoacidity, decreased the resisting powers of the organism against the entrance of the virus of tuberculosis and, in fact, rendered the soil more favorable for its growth. The experiments here reported consisted, not in an estimate of the metabolic exchange, but in analysis of the entire organism with reference to the mineral constituents. For this purpose the body of a child was employed which had succumbed to a general tuberculosis, and the results obtained by the chemical analysis compared with those already known of normal infants. The figures obtained show that the total ash from the child which died of tuberculosis was about the same as that from the four months' infant which succumbed to ordinary gastroenteritis, therefore no marked demineralization was present. The amount of lime, phosphorous, and magnesia was found to be somewhat less than expected. But this decrease in the mineral constituents was probably not specific for tuberculosis, but undoubtedly resulted from the well-marked rachitis from which the tuberculous child also suffered and from which the other infant was free. The potassium salts were unchanged, and the sodium and chlorine constituents were somewhat diminished. These observations seem to show that the theory of demineralization does not find any application in tuberculosis.

A New Method of Cardiac Examination.—M. Katzenstein proposes a method by which it is possible to estimate the functionating power of the heart, especially when about to be subjected to the strain of a surgical operation. Most of the methods for making this determination require that the patient be subjected to various exercises which necessitate his getting up out of bed, and this, in many cases, is a great disadvantage. The author's method is based on numerous observations made in animals, normal, healthy animals, that ligature of the larger arteries call forth increased activity on the part of the heart, which is marked by increased blood pressure, but no change in the pulse rate. This phenomenon remains until the collateral circulation is fully established, and gradually there is a return to the normal after several weeks as the resistance diminishes. Marked resistance in the arterial circulation brings about increased heart action, and this observation constitutes the rationale of the procedure, the technique of which is as follows: the pulse rate and the blood pressure are determined in the patient in a quiet, reclining position. Both iliacs are then compressed for a period of from two and a half to five minutes in the inguinal region and the changes noted in the pulse rate and the blood pressure. In a normally acting heart there is found an increase in the blood pressure of from 5 to 15 mm., of the mercury column, while the pulse rate remains the same or is slightly diminished. With a hypertrophied heart, the blood pressure is raised from 15 to 40 mm. while the pulse remains the same or is increased. Where there is a slight insufficiency, the pressure is o, and the pulse the same or greater. A marked cardiac insufficiency is accompanied by a minus pressure and an increase in the pulse rate. The method is simple and readily applied, and the only possible unfavorable circumstance is the effect of physical excitement, but with care this may be avoided.

Berliner klinische Wochenschrift, May 30, 1904.

A Case of Sinus Pericranii.—M. Littauer adds a tenth case to the nine already reported of this rare condition, which Stromeyer first described as a tumor under the pericranium which contains venous blood, and is in communication with the cerebral sinuses either directly or through the medium of the venous canals in the cranium. A number of varieties exist. A man of twenty-four years received a blow on the head which did not appear to be followed by serious consequences; but two weeks later, after having been in stooping position for a time, a soft swelling was noticed in the right temporal region, which disappeared when the erect posture was resumed. The tumor appeared intermittently whenever the head was bowed low, but was not accompanied by any symptoms. Examination was practically negative as regards the anatomical parts. The possibility of the fluid being the cerebrospinal liquor could be excluded, as neither a meningocele or a cerebral hernia was present. The contents must therefore have been blood which remained in communication with the general circulation. This could be brought about by a rupture of one of the veins of the diploei or an emissary vein from the injury and subsequent retraction and closure of the vessel prevented by the dense adhesions of these structures to the surrounding tissues.

A New Hæmostatic.—Theo. Landau presents a new drug obtained from the spleen by autolysis which, he claims, has well marked hæmostatic properties. He applied it successfully in a number of cases of menorrhagia and metrorrhagia in the form of injections. He is unable to report definitely on its mode of action, but thus far has determined that the effect does not depend on any contractile power exerted on the blood-vessels similar to that resulting from the use of suprarenal extract. Apparently the effect is produced by some influence exerted on the coagulation of the blood, and the action is a chemical one. Local application is ineffective. Its sphere of action seems to be in capillary hemorrhages, and the author has found it of particular efficiency in gynecologic affections. He believes, however, that it would also be of value to various internal diseases accompanied by hemorrhages, gastric ulcer, intestinal or pulmonary hemorrhages,

etc. He recommends the remedy, not as a substitute for surgical treatment, but only in those instances in which more radical measures are not immediately indicated. Hirsch reports on the method of securing this product and its mode of employment. The drug is an extract from the spleens of horses obtained by the method of antiseptic autolysis. Experiments on animals showed a reduction in the blood pressure and apparently an increased tendency of the blood to coagulate. The remedy is given by intramuscular injections in the gluteal region by preference, but may also be given subcutaneously. No unpleasant after-effects were noted. Fifty-nine cases of various forms of uterine hemorrhages were treated with good results in almost all cases, sufficient to stamp the article as an excellent styptic which is worthy of further trials.

A Case of Fatal Gastric Hemorrhage.—H. Hirschfeld reports a case in which a fatal issue was brought about by a gastric hemorrhage due to a ruptured arterial aneurysm of one of the gastric vessels. The patient was a man of twenty-eight years, who, during the course of seven years, had had severe gastric hemorrhage thirteen times. The patient was a hæmophiliac, and there was also a family history of this condition. To the last of these attacks the man succumbed, and at the autopsy the source of the bleeding was traced to a small miliary aneurysm situated at the base of a superficial ulcer in the gastric mucosa. There were also a number of varices in the immediate vicinity, but no evidences of ruptures of these. The author thinks that the fatal issue would have been avoided if the patient had not been a hæmophiliac. The differential diagnosis of such cases would be difficult, but in a case in which there are repeated hemorrhages from the stomach without the presence of pain, aneurysm should be thought of. Surgical interference would, in this instance, have been appropriate, but the patient's history forbade such a step being taken. The etiology in this case may be traced to a chronic alcoholic gastritis, which was found to have involved the mucus membrane with different degrees of intensity. The hæmophilia probably also favored the production of the aneurysm and the varices. One of the objects in reporting the case was the possibility of being able to restrict the number of so-called parenchymatous hemorrhages of the stomach, in which the source of the bleeding has never been definitely ascertained.

Münchener medizinische Wochenschrift, May 31, 1904.

The Dangers of Potassium Chlorate.—Buri believes that the dangers attendant upon the use of this drug are largely overestimated. He comments particularly on its value in the form of a tooth paste as a prophylactic against mercurial stomatitis. Fatal cases of poisoning have only resulted from the ingestion of large doses of a concentrated solution in error, and to avoid any possibilities of this occurrence, he advises giving the drug only in the form of compressed tablets or tooth paste. Only small daily doses are necessary and no unfavorable effects have been observed. It is also claimed that none of the so-called cases of chronic poisoning have ever been satisfactorily demonstrated.

Results of the Bassini Operation for Inguinal Hernia.—F. Frankel draws the following conculsions from a series of 250 cases operated on by this method. He believes that the only contraindication against operating in any case of non-strangulated inguinal hernia is that furnished by the patient's general condition, and if it is a question of anæsthesia, recourse should be had to local anæsthetics if possible. Operation should always be indicated, unless this conflicts with the statements just made, whenever other measures have failed or are inapplicable. But even when a truss apparently suffices, the advantages of radical operation should be made clear to the patient, especially as it does away with the dangers of strangulation. Among 185 cases out of 250 which could be traced, recurrences were found in seven. Secondary operations are recommended and were successfully done in three.

French and Italian Journals.

Treatment of Incontinence of Urine by Lumbar Puncture.—Babinski and Poisseau report that lumbar puncture may bring about a cure in incontinence of urine, whether of neurotic or of organic origin. These authorities cite cases showing the effect of lumbar puncture in this condition. One patient, a syphilitic, had suffered from organic spasmodic paraplegia for two years. When the incontinence reappeared, a second puncture overcame it. The method was not successful in the case of an atoxic patient who had been incontinent for four years.—*Journal des Praticiens*, May 7, 1904.

Semeiology of Stomatitis.—Fernand Levy, in discussing stomatitis, speaks of it as having the character of a local infection or as a complication of an illness by which the whole organism is affected. The observance of careful hygienic details in relation to the mouth, regular cleansing of the teeth, and immediate attention to carious teeth will do much to prevent stomatitis. In general maladies, the most minute attention to the care of the mouth, such as frequent rinsing of the mouth and teeth, will prevent the complication of stomatitis. Certain inflammations, such as mercurial stomatitis, can be avoided by special precautions. When once the inflammatory manifestations have appeared, local applications of the tincture of iodine, or methylene blue, cauterization with silver nitrate and antiseptic washes will rapidly ameliorate the condition.—*Gazette des Hôpitaux Civils et Militaires*, June 4, 1904.

Two Cases of Subcutaneous Angiomata in Children; Treatment.—Adrien Besson cites these two cases which came under the service of Duret. The first child was twenty months old. The tumor was about the size of a small nut, and of violet color. The mother had always noticed it, but for eight days it had been sensibly increasing in size. It was extirpated and dressed. At the end of eight days the bandages were removed and only a slight scar remained. The second patient was a child of sixteen months. The vascular nævus was of the size of a nut situated in the subclavicular region. Its base was large. Injections of Piazza's liquid were made daily for eight days. The result was excellent, but the child was removed before the tumor had entirely disappeared. The writer believes that when these tumors are limited and not in a position where scars are to be dreaded, total extirpation is indicated. When they are extensive with a large base electrolysis is the proceeding of choice. The coagulating injections of Piazza are indicated in intermediate cases.—*Journal des Sciences Médicales de Lille*, June 4, 1904.

A Special Type of Enteric Infection by Bacterium Coli.—F. Sicuriani has observed a small epidemic of five cases of fever similar to typhoid in many ways, but resulting from infection of the intestine by the bacterium coli. Such an epidemic appeared in Siena, in 1895, with a mortality of 70 per cent. Microorganisms were isolated from the fæces in the form of cocci, bacill,i and diplobacilli, resistant to Gram's stain. The cases observed by the author had a continuous, remittent or intermittent fever, varying from 37.8° to 39.5°, with a pulse and respiration that were little changed, and a good general condition. In most cases there was constipation, with hard, yellowish fæces, and meteorismus, but with little tenderness of the abdomen on pressure. There were no nervous manifestations, the spleen was not enlarged, and there was no eruption. Indican, creatinin, and urea were increased.—*La Riforma Medica*, May 11, 1904.

Rapid Recovery from Puerperal Septicæmia after Administration of an Injection of Formalin.—Hoerschelmann has had excellent success with the formalin treatment in a case of puerperal septicæmia. The patient was a primipara who was delivered of a dead fetus. The amniotic liquid and the placenta had a strong putrid odor. The patient quickly developed all of the symptoms of a violent septicæmia. The writer first administered nine drops of the tincture of opium by mouth, and then gave an injection of 600 c.cm. of salt solution with the addition of eight drops of a 4-per-cent. solution of formic aldeyhde. Within two hours, marked improvement supervened. About a quart of the solution escaped with fæcal matter after the injection Within five days the fever was entirely dissipated. The writer thinks that the history of the case deserves attention. He thinks that it is not prudent to give more than five drops of this solution in an injection.—*Gazette de Gynécologie*, June 1, 1904.

Infectious Disseminated Gangrene of the Skin Consecutive to Typhoid Fever in a Child of Thirteen Years.—B. Auché and Latreille report this case. The patient after an abdominal traumatism was taken ill with typhoid fever. Several vesico-pustules were noted in the center of a red area in the dorsal region. Within the next few days there appeared disseminated areas of cutaneous gangrene. They came the most often in the location of the vesico-pustules; one time in a red area which had no vesico-pustules; at other times they appeared where there were cutaneous abecesses. The pustules sometimes showed the characteristics of the pustules of variola. There were numerous cutaneous and subcutaneous abecesses. The vesico-pustules and the unruptured pustules, like the cutaneous abecesses, contained the yellow staphylococcus in pure culture. The gangrenous areas gave in culture the yellow staphylococcus and the colon bacillus. There were no diphtheria bacilli, nor anærobic microbes. The staphylococcus inoculated in the rabbit caused the formation of a large abscess which opened, and healed rapidly without any trace of the gangrenous process. The colon bacillus caused only a subcutaneous induration which disappeared very rapidly.—*Journal de Médicine de Bordeaux*, May 8, 1904.

SECTION ON GENERAL MEDICINE.

Third Day—Thursday, June 9.

Etiology of Cholecystitis and Cholelithiasis.—Dr. WALTER L. BIERRING of Iowa City, Iowa, called attention to the necessity of recognizing that this viscus constituted one of the most vulnerable points for infection in the abdominal cavity; it was analogous to the appendix and the fallopian tubes, except that while microorganisms were more or less constantly present in the lumen of the appendix normally the gall-bladder was generally free and infection of the gall-bladder concerned itself more with the contents than with the walls, the sterile bile becoming a culture medium for microorganisms. The gall-bladder, situated as it was between the bacteria hordes of the intestine and of the liver, was liable to infection. Experiments have demonstrated that a great many microorganisms flourish in the gall quite vigorously. Clinical and experimental observations showed that infection occurred in two ways: (1) by way of the blood, descending or hæmatogenous; (2) ascending, or by way of the common bile duct. Stoppage of the bile by gallstones or foreign bodies favored the growth of bacteria. The etiologic relation of cholecystitis and cholelithiasis had been found to be so close that those factors which pertained to the etiology of gallstones would also be catisative of cholecystitis. He said that cholelithiasis was very rare in early adult life, occurring usually after the age of forty. It was far more frequent in women than in men; this was probably due to child-bearing, tight-lacing, sedentary habits, and constipation. The deduction was made from the accumulated evidence of experimental and clinical knowledge of the pathogenesis of gallstones that while the essential cause was usually cholecystitis, there were other factors at work beside infections, and special attention should be given infectious diseases and altered metabolism which promoted a change in the bile chemically, so that it constituted an irritant. He was of the opinion that cholecystitis and cholelithiasis were secondary affections and that they would soon become rare diseases if we could eliminate the influences of improper wearing apparel, lethargic habits, constipation, gastric and intestinal catarrhal disorders.

Diseases of the Gall-bladder and Bile Ducts, in Relation to Diseases of the Gastrointestinal Tract.—Dr. BERTRAM W. SIPPY of Chicago presented this paper. He called attention to the close anatomical proximity of the gall-bladder and bile ducts to portions of the gastrointestinal tract. He divided diseases of the stomach and intestines rising from disease of the gall-bladder into those of nervous origin and those due to direct extension of the anatomical disease. Functional activity of the stomach and intestine was influenced in a reflex way by disease of the biliary tracts, but produced no serious results, while the extension of anatomical disease was fraught sometimes with most serious consequences. Pyloric and duodenal obstruction from cholecystitis coexistent with pyloric stenosis was serious. In the management of duodenal and pyloric obstruction consequent upon an attack of cholecystitis he advised postponing operation until the patency of the pylorus had been tested by rest and rectal feeding, except in cases in which immediate operation was necessary, because of serious local inflammation. Gastroenterostomy should rarely be performed at this time unless there was evidence of old pyloric or duodenal obstruction. If, after rest and rectal feeding, the obstruction persisted and the condition of the patient permitted, an operation for cholecystitis might be combined with gastroenterostomy. It was possible that a gallstone might occlude the lumen of the bowel with fatal result. In making a diagnosis between gastric or duodenal ulcer and cholelithiasis it was well to remember that there was not a single symptom of one that might not be present in the other. A fairly accurate differential diagnosis might be made between the two conditions by making a careful study of the whole clinical picture, not laying too much stress on any one symptom.

Diagnosis of Cholecystitis and Cholelithiasis.—Dr. PARKER SYMS of New York City said that the important diseases of the gall passages were (1) inflammatory disease of the gall-bladder and gallducts without stone; (2) gallstones in the gall-bladder and gall ducts without inflammation; (3) inflammatory conditions of the region surrounding the gall passages causing obstruction by pressure or distortion; (4) neoplasm of the gall passages, benign and malignant, with or without gallstones and with or without inflammatory disease. The prominent symptoms of these affections were: pain, tenderness, fever and chills, vomiting, change of pulse rate, collapse, tumor jaundice, urinary changes, blood changes, and stools. The pain was colicky, occurring often when the stomach was empty; tenderness was localized to the region involved, usually opposite the juncture of the ninth rib with its costal cartilage; fever was of an acute type, subsiding as rapidly as it rose; vomiting was of a reflex nature and independent of nausea, pulse was accelerated and tension increased; collapse might occur in severe attacks, tumor might be felt below the free border of the ribs; jaundice might be present or absent according to the degree of obstruction of the flow of bile; urinary changes were of interest in determining the presence and degree of jaundice, and the amount of leucocytosis was helpful in determining the presence of suppuration; stools showed the presence or absence of bile. X-ray examinations had thus far given no satisfactory results. He said that bile-passage diseases should be differentiated from gastric ulcer, appendicitis, renal colic, pancreatitis, phlebitis portalis, angina pectoris, empyema, subphrenic abscess, malignant disease of the pyloris, duodenum, pancreas, liver, kidney, etc. He described each of these affections and presented a chart of the diseases of the gall-bladder and ducts which aided in a more accurate diagnosis.

The Treatment of Cholecystitis and Cholelithiasis.—Dr. LUCIUS W. HOTCHKISS of New York City called attention to the general tendency to place diseases of the gall-bladder and bile ducts within the category of surgical affections. He divided treatment into two classes, first the medical or palliative, and second, the surgical or radical. He spoke of the opinion of some experimenters who thought that gallstones might be dissolved by administering sodium glycocholate or alkalies and bile salts with a rich diet. The rationale that aimed to relieve congestion and increase the flow of bile was perfectly sound. He thought that the great point to be determined was the border line between balneological and surgical procedures. He believed that as we learned to diagnose with more certainty there would be less call for difficult and dangerous operations upon the common duct and fewer cases requiring cholecystenterostomy. The danger in operation lay principally in delay. He was of the opinion that choledochostomy, choledochectomy, choledoenterostomy were possible only in rare conditions, and operations upon the hepatic duct were still in their infancy. Experience had shown him that certain cases seen in the first mild attack subsided quickly under medical treatment; cases in subsequent mild attacks were ideal ones for cholecystectomy, while in cases of repeated severe attacks cholecystostomy was always justifiable and the operation of choice, cases showing evidence of a mild local infection for a short time and suddenly developing signs of sepsis and peritonitis required early operation. It was wise to treat cases of common duct obstruction by calculus, expectantly for a week or two. In these cases the treatment must ultimately be surgical.

Ergot in General Practice.—Dr ALFRED T. LIVINGSTON of Jamestown, N. Y., endeavored to show that inefficient tone of unstriated muscular fiber was a common and serious element of disease, and that it was important to guard against or correct such an abnormal state of the tissues. He thought that the abnormal disturbance of blood distribution depended upon a relaxed state of the muscular coat of the blood-vessels. The location, degree, and persistence of such vascular relaxation, together with irritants or etiological factors, determined a variety of diseases which would not occur if there was a good tone of the vascular walls. He said that but a small percentage of humanity possessed a good state of tone; in all the unstriped muscular fiber of the body being thus more liable to disease. For inflammation of the arteries, veins, and lymphatics he prescribed rest for from two to five months and daily injections of ergot. Septic inflammation of veins and lymphatics had repeatedly yielded to treatment. He considered the serious and fatal elements of febrile disease in detail, and said that the evidence afforded by the action of ergot in shock was that the condition was not so much a paralysis of vasomotor centers as it was a disturbance of the equilibrium of the circulation, and the indication was to contract the dilated and engorged vessels and to establish an active circulation. Ergot was the agent that would do this. He regarded the toning of relaxed unstriped muscular fiber as of great importance in a variety of diseases and of vital importance in many instances.

Dr. HERMAN GRAD of New York reported excellent results from the use of ergot before, during, and after surgical operations in greatly relieving the nausea and vomiting which followed the administration of anæsthetics.

Dr. JAMES J. WALSH of New York spoke of the cases in Dr. Wakefield's service in which ergot had been of great benefit. He spoke of the relaxation of the blood-vessels in the abdominal region, and that it was claimed that two-thirds of the blood in the body could be contained in the abdominal vessels. By toning up the abdominal vessels, as by the administration of ergot, the circulation could be improved.

Dr. ALEXANDER LAMBERT of New York related his experience with 8,000 cases of alcoholism at Bellevue Hospital. The death rate in nine years had been about 3 per cent. in those patients with a wet brain condition, and that this death rate had been reduced about 44 per cent. by the use of ergot.

The Differential Leucocyte Count as an Aid to the Diagnosis of Fevers.—Dr. WM. KRAUSS of Memphis, Tenn., read this paper and presented the following conclusions: (1) It is not so much the absolute increased per cent. of large lymphocytes which is diagnostic of malarial infection as the relative increase over the small lymphocytes. (2) In cases of malarial infection without much fever and without quinine history, the polynuclears are markedly diminished and the large lymphocytes very much increased in proportion. (3) In the absence of an adenopathy, possibly also of influenza and measles, the above finding is positive evidence of present or very recent malarial infection. (4) During the rise of a malarial fever, or as a result of quinine therapy, the polynuclear leucocytes may reach 80 per cent., but in that event the large lymphocytes exceed in number the small ones. (5) In malarial hæmoglobinuria any of the various blood-findings characteristic of malarial fever may be present in any stage, and there is no evidence now at hand to explain this. (6) Malarial and typhoid fevers can be more positively differentiated from fevers of sepsis, pneumonia, rheumatism, malignant tumors, etc., by the differential leucocyte count than by the hæmatometer and it can be done on dried films sent from the bedside. (7) Malarial infection makes a strong impression upon the leucocytes no matter what other disease it is associated with. (8) It is said to rule out typhoid fever when the malarial variation is [illegible] as it is not malaria modifies the therapeutic test may decide before a Widal would appear. (9) In a gradually developing fever, the absence of marked increase in large lymphocytes or polynuclears during the first week justifies a preliminary diagnosis of typhoid fever.

The Pathogenesis of Uræmia and Eclampsia.—Dr. ROBERT N. WILLSON of Philadelphia presented this paper and offered the following conclusions: (1) That it is probable that there are at work in the cerebrum, as well as throughout the system of uræmic subjects, at least one, and probably several toxic substances, which exert their influence more or less locally upon the cortex. (2) That it is equally certain that other portions of the brain than the cortex are also acted upon, as in the production of coma, etc. (3) That no small part in the production of the uræmic and eclamptic condition is played by intracranial pressure, due to a temporary excess of fluid, whether acting independently of, or in conjunction with, the toxic substances already mentioned. (4) That lumbar puncture will at least temporarily relieve certain of the symptoms most readily ascribed to localized intracranial pressure; and that cases in which pressure is the main factor, drainage of the spinal canal may save life. The procedure, together with free bleeding, purging, and diuresis, should be added to our routine treatment of the condition. (5) That transfusion of normal salt solution by intravenous injection or hypodermoclysis, except in cases of anuria, or a greatly diminished urinary secretion, is contraindicated, as tending to increase the liability to saturation of the tissues. (6) That the results of lumbar puncture in the three cases cited in the paper would not warrant the assumption that relief of intraspinal or intracranial pressure could alone be depended upon to cure the uræmic or eclamptic condition, provided the toxic influence was a prominent one in a particular case.

Dr. JAMES TYSON of Philadelphia thought that we must consider some toxic agency responsible for the phenomena.

Dr. ALEXANDER LAMBERT of New York said that in eclampsia the lesions noted were often identical with those of acute yellow atrophy of the liver.

Dr. ROBERT N. WILLSON of Philadelphia emphasized the fact that when bloody fluid was withdrawn by lumbar puncture, the cases terminated fatally, whereas if clear fluid was obtained patients could recover.

Amœbic Dysentery: Its Local Lesions and Treatment.—Dr. JAMES P. TUTTLE of New York read this paper which was based upon his personal experience with seventy-four cases of amœbic dysentery, together with the information that he had gained from literature. The invasion of the colon by the amœbæ dysenteriæ caused this disease. The life of the amœbæ was indefinite at the body temperature, but at a temperature of less than 70° they lost their motility and life became extinct; heat would not restore them. The treatment should be directed to the local lesions, the destruction of the amœbæ and the prevention of a redevelopment from the spores. These spores were buried in the tissues and superficial washing would not destroy them. Simple cold water was very effective. The patient was placed in the knee-chest position and the bag elevated about three feet above the level of the hips. The water was allowed to run in slowly, the amount used being regulated by the tolerance of the patient. Local measures should be employed in the treatment of ulcers of the rectum and sigmoid. As it was possible that the appendix might be the seat of amœbic infection, it was wise to remove it in those cases in which the appendix was utilized as a means of introducing the cold water into the large intestine. In seventy-three cases treated by this method seventy cases had been cured.

Dr. PERRY PRACK of Chicago said that it had been his experience that the various solutions used had very little effect upon the amœbæ. He referred to oil, which acted as a powerful irritant and which excited peristaltic hyperæmia and had more or less effect upon the plasmodium. He employed hot water beginning with the water at a

temperature of 115° F. and gradually raised it to 131. After every treatment the amœbæ disappeared. He followed this by the use of ice water and the results were better than though he had used ice water alone.

Dr. A. W. Warden of Union Hill, New Jersey, gave an account of the beneficial results that he had obtained from the use of chaparro or a nargosa.

The Family Physician as a Factor in the Solution of the Tuberculosis Problem.—The speaker said that the family physician should be carefully trained in the early recognition of tuberculosis and should make calls at regular intervals whether the family was ill or not. He thought it important that there should be periodical examinations of the chest of each member of the family. At the slightest indication of predisposition to tuberculosis preventive measures should be inaugurated. He pointed out the need of more sanatoria, hospitals, better tenements, etc. The family physician should be the friend of the family as well as the medical advisor, and as such should be able to prevent the marriage of a consumptive.

Has Influenza Been a Causative Factor in the Increase of Appendicitis.—Dr. Phillip Marvell of Atlantic City gave a statistical review of the periods from 1884 to 1894, and from 1894 to 1904, as taken from the records of the Episcopal and Pennsylvania Hospitals. A comparison of these records showed that there had been a great increase of appendicitis during the latter period and also a great increase over all the more important pelvic and abdominal inflammatory diseases. He did not think this increase could be entirely explained by our better knowledge of diseases. He said that if we were unable to arrive at fixed conclusions we could make the following deductions: (1) That appendicitis had increased in the past five years much more rapidly than in either of the previous five-year periods studied. (2) That the accessory cavities were more frequently attacked, and when diseased, more likely to be aggravated by influenza than by other diseases. (3) That there is more than the possibility of the existence of chronic interstitial influenza, therefore a probability of its causative relation to appendicitis. (4) That the observations set forth in the abstracts which he had set forth in the course of his paper must be admitted as a measure of proof in favor of the inferences drawn and the conclusion arrived at.

Fourth Day—Friday, June 10.

Aneurysm of the Innominate Artery.—Dr. Albert P. Francine of Philadelphia summarized his paper as follows: A delayed and weakened beat in the right radial, absence of pulsation in the right temporal, a turgid external jugular, in association with paroxysmal attacks of dyspnœa and pain at the root of the neck or referred to the right side, were very suggestive of innominate aneurysm. The two signs to which he wished to call special attention were the regurgitant quality in the right radial pulse, which he did not think had been described before in this connection, and the more convincing sign in the supersternal notch behind and above the right sternoclavicular articulation in association with a distinctive angle of reëntry in the second interspace. If these aneurysms were not relieved by operation they would rupture sooner or later. In operating he employed distal ligation of the right common carotid and subclavian, one or both, either consecutively or, if necessary, at the same time. In uncomplicated cases this operation had proved highly successful, the sac becoming obliterated by organized clot.

Symposium.—"Arthritis Deformans."

Pathology and Etiology of Arthritis Deformans.—Dr. Thomas McCrae of Baltimore read this paper. He said that in our present uncertain state of knowledge of arthritis deformans it was important to determine whether we had one or more diseases included under this term. He described the anatomical distinctions between two types and expressed the view that they were varying manifestations of the same disease. This seemed to be supported by the fact of their occurrence in the same person. He reviewed the various theories as to etiology and favored the possibility of an infection as being the cause. There was as yet no positive evidence of a specific infection as against the possible agency of various ones.

Symptomatology in Arthritis Deformans.—Dr. James J. Walsh of New York presented this paper. He was of the opinion that uric acid had nothing to do with rheumatic conditions. Arthritis deformans could be traced in history in nearly all times, bones that had been buried perhaps 5,500 years ago showed the signs of the changes in arthritis deformans. English authorities have divided arthritis deformans into three groups: (1) The disease commonly known as osteoarthritis, often confined to the hip-joint and most common in old men. (2) A disease in milder form represented by deformities occurring in the terminal joints of the fingers and most common in women in middle life. (3) This form was one simulating acute rheumatism and produced lasting changes in the joints; it had a tendency to recur and ultimately cripple the victim permanently. It occurred more commonly in young women. The fact that the salicylates failed to reduce the fever or to lessen the pain and discomfort was the most characteristic differential diagnostic symptoms. Probably the most important feature of this affection was its tendency to recur.

The Treatment of Arthritis Deformans.—Dr. Clarence Edward Skinner of New Haven, Conn., said that for a routine treatment, to be modified according to the requirements of the individual case, was the following: (1) A diet as generous as could be digested and assimilated by the individual, and consisting largely of red meats. (2) Rest in bed for at least ten hours out of twenty-four. (3) A pill consisting of $\frac{1}{10}$ of a grain of strychnia sulphate and $1\frac{1}{2}$ grains of ferrous iodide three times daily half an hour before meals, and in emaciated cases one to four drachms of cod-liver oil three times daily after meals. (4) A dose of some one of the mineral waters before breakfast two or three times a week if constipation was present. (5) A body dry hot air treatment two or three times weekly. (6) Central galvanization two or three times weekly. (7) A general application of mechanical vibratory stimulation two or three times weekly. (8) A static electric application at least once every day, using in acute cases the Morton wave current localized over the affected joints or spine; in chronic cases, of long thick sparks to the affected joints one day and the Morton wave current localized over these joints the next. (9) With ankylosed joints in which the acute condition had subsided and the functional impairment was not due to osteophyte formation, passive movements every day, in the form of alternate flexion and extension, the attempt being made to increase the excursion of the manipulated member each time, was of considerable use. Fifty-one cases treated in private practice during the past four years showed what could be done by the application of this treatment. These cases were summarized as follows: Out of 24 patients who were totally incapacitated for the performance of ordinary duties, 6 were restored to a condition of unimpaired usefulness, 3 to a condition of but slight impairment, and 8 of the remainder discontinued treatment prematurely; out of 27 who were partially incapacitated, 7 were restored to unimpaired usefulness, 4 to but slightly impaired usefulness, and of the remainder 14 discontinued treatment prematurely. Out of 36 patients who were suffering constantly from pain, 10 were relieved entirely, in 12 pain was reduced to some extent, and 11 of the remainder discontinued prematurely. Of 15 cases in which pain was present, only on movement, 5 were relieved entirely, 3 were greatly relieved, and of the remainder 8 discontinued treatment prematurely; of 25 cases in which partial ankylosis of one or more joints was present, 13 were completely relieved, 12 partially, and 11 discontinued prematurely. Of 27 cases in which the general condition was bad when the treatment was begun, 10 were restored to normal health, 12 were greatly improved; of

19 cases in which the general condition was fair, 5 were restored to normal health and 8 were greatly improved.

Dr. GOLDTHWAIT of Philadelphia did not think the nomenclature was important so long as we knew what we meant by the terms used. He said that Dr. McCrae had mentioned the atrophic and hypertrophic types, but there were many cases encountered which he termed infectious arthritis. It was quite possible to distinguish these by means of the radiograph. In the disease as described by Still he did not know whether it was atrophic or hypertrophic in character. He thought it strange that we should have these two types of the same disease, and no man had stated that from the start the disease never became chronic, and others held that at the start it was chronic and never became acute.

Dr. ALLEN JONES of Buffalo did not think that we ought to throw out the term chronic rheumatism until we had seen demonstrated positively either the specific cause for acute articular rheumatism or a specific cause for acute rheumatism and arthritis deformans.

Dr. DELANCEY ROCHESTER of Buffalo said that the treatment outlined by Dr. Skinner was impracticable to the general practitioner because of lack of apparatus. He thought the general practitioner could get good results by care and watchfulness, and that the application of hot air, though not so hot as advocated, was productive of good results. He also recommended the use of the cabinet and of friction.

How the General Practitioner Should Treat Gonorrhœa.—Dr. FERD. C. VALENTINE of New York presented this paper and offered the following conclusions: (1) Every general practitioner was practically competent to treat successfully uncomplicated anterior gonorrhœa, if he would devote as much attention to this as he did to any one other disease. (2) Every patient with gonorrhœa was entitled to the services of his family physician, just as much as though he had acquired some other disease in consequence of drunkenness or other violation of morals. (3) The general practitioner who declined to treat uncomplicated anterior gonorrhœa avoided one of his most sacred duties to the profession and to humanity. (4) The patient who, because he had gonorrhœa, refused the services of his family physician was likely to become an opponent of scientific medicine, to the detriment of his health, that of his family, and that of the community. (5) The scientific treatment of this form of gonorrhœa was perfectly within the power of the general practitioner. (6) The irrigation treatment was as yet the most effective method and was most in accord with the modern scientific understanding of the disease.

Problems for the Tuberculous Convalescent.—Dr. A. MANSFIELD HOLMES of Denver, Colo., read this paper. He said that the patient required suitable and nutritious food as well as pure air and sunshine; that without suitable food the fresh air and sunshine availed but little. It was difficult to impress patients with the importance of proper living, and for this reason sanatoria treatment surpassed home treatment. The danger lurked in a latent form long after all subjective symptoms had disappeared. To form a correct estimate of convalescence, one should form a composite picture of all the available clinical evidence. If there was a gradual gain in weight extending over a comparatively long period, and if this gain was accompanied by a gain in strength, which was also permanent, and if the cough, sputum, and bacilli diminished and disappeared, a cure might be considered as practically established.

Election of Officers.—*Chairman*, Dr. Richard Cabot of Boston; *Secretary*, Dr. Joseph Miller of Chicago; *Executive Committee*, Drs. Frank A. Jones of Memphis, Tenn., W. S. Thayer of Baltimore, and Alexander Lambert of New York.

SECTION ON DISEASES OF CHILDREN.

Third Day—Thursday, June 9.

Hæmaturia as the Earliest or Only Symptom of Infantile Scurvy.—Dr. JOHN LOVETT MORSE of Boston reported a number of cases illustrating the fact that hæmaturia was a not uncommon symptom of infantile scurvy. It might be the earliest symptom of infantile scurvy, and therefore, for a time, the only symptom. Scurvy was the most common cause of uncomplicated hæmaturia in infancy.

Dr. WILLIAM L. STOWELL of New York City said that this entire subject of disturbances of the blood in children was still very much confused. If there was a special germ or diathesis underlying the condition, it had not yet been found, nor had a special remedy been discovered. Hæmaturia was probably a more common symptom in these cases than was generally supposed. A more systematic examination of the urine of young infants was desirable.

Dr. H. M. MCCLANAHAN of Omaha called attention to the value of Dr. Morse's paper from a clinical standpoint. Scurvy was readily curable if recognized within a reasonable time, before secondary changes had taken place.

Dr. J. ROSS SNYDER of Birmingham, Ala., called attention to the fact that this early and important symptom of scurvy had probably been frequently overlooked.

Intestinal Obstruction in Children.—Dr. JOHN F. ERDMANN of New York City, in this paper, discussed intussusception, strangulated hernia, post-operative bands, and Meckel's diverticulum as possible causes of intestinal obstruction in children. The major part of the paper, however, was devoted to intussusception. The diagnosis of this condition was not difficult, although the symptomatology, as given in the former text books on diseases of children, etc., should be rewritten with a view of placing most stress upon blood or bloody mucus in the stools, instead of upon the presence of a sausage-shaped tumor. In over 60 per cent. of a series of twenty-eight cases seen by Dr. Erdmann, twenty-four of which he operated on, no tumor of any kind was palpable per rectum or through the abdominal wall. On the other hand, there was not a single case in which blood or bloody mucus was not found either upon the diaper, in the commode, or expelled from the anus after digital examination. Sudden pain was almost invariably the first symptom that the child manifested; then a degree of shock, varying in intensity, and efforts at defecation took place. These symptoms were followed by manifestations of spasmodic pains, accompanied by a peculiar whining cry or fits of crying. During the first hour or two, the abdomen was lax, and no marked evidence of pain was produced by palpation. No tumor could be felt unless the intussusception was of considerable extent and took place rapidly. After a few hours, depending upon the degree of obstruction, abdominal distension and evidences of complete obstruction occurred. Although some fæces might be expelled with the bloody rectal contents, they were due entirely to the fact that those contents were below the point of obstruction. When a tumor was present, it was not usually the proverbial sausage-shaped tumor, but was more apt to be round or nodulated, and moderately movable. There was usually an accelerated pulse, and an elevation of temperature from one to two and one-half degrees.

Rectal enemas during the first few hours were not productive of harm, and might, though rarely, be followed by reduction. This occurred but three times in the twenty-eight cases observed by the writer. The condition usually demanded prompt surgical interference, and his experience had led him to oppose temporising with air inflation or water injection. Although these little patients bore operative interference quite well, it was significant that his greatest mortality rate occurred in those cases that required the longest time. Chloroform was the anæsthetic used in all his cases. The incisio was invariably

made in the middle third of the right rectus, and usually did not exceed two inches in length.

Dr. ISAAC A. ABT of Chicago called attention to the fact that all cases of intestinal obstruction in children were not of mechanical origin. Some were of a paralytic nature occurring in the course of pneumonia and other systemic affections. Others were apparently dependent on the ingestion of certain kinds of food, producing ptomain poisoning and intestinal infection. The speaker said he did not believe that such cases could be benefited by surgical interference.

Dr. LOUIS FISCHER of New York City said his experience with this class of cases had impressed him with the belief that children did not bear laparotomy well. He could recall at least six cases in which laparotomy was done, and all resulted fatally.

Dr. S. W. KELLEY of Cleveland, Ohio, said that spontaneous reduction was occasionally seen in intussusception, and it might take place under the use of opium, but the use of the drug should be limited to the beginning of the attack. The method of inflating the bowel with air was useful in certain cases if properly done, and was preferable to water pressure. One objection to the use of air was that it was difficult to gauge the amount of pressure. He had overcome this difficulty to some extent by first introducing air, and then water, which could be more easily handled and by which the air pressure was regulated. He thought a pressure of four or five pounds was sufficient, and this should be kept up for a period of from 15 to 25 minutes. He considered this more effective than a higher pressure kept up for a shorter time.

Dr. SAMUEL MCC. HAMILL of Philadelphia said it had been shown experimentally that irritation of the rectum produced reversed peristalsis, and this fact might have some bearing on the spontaneous reduction occurring in some cases of intussusception.

Dr. A. JACOBI of New York City said that the reversed peristaltic wave would probably be interrupted at the place of intussusception.

Dr. JOHN LOVETT MORSE of Boston said that their experience at the Infant's Hospital in Boston indicated that babies bore not only laparotomies, but other severe operations, well, provided they were kept warm during the operation.

Dr. Erdmann, in closing, said that the introduction of air or water in these cases usually proved ineffective, and was so much time lost. One reason why the injection method was ineffective was that the air or water could not be held in, and readily escaped through the sphincter. The danger of rupture of the gut must also be borne in mind. After the intussusception had existed for any length of time, reduction by the injection method was out of the question. In such cases the coats of the intestine were soggy and œdematous, and very careful manipulation was necessary to effect reduction. As regards the mortality of the operation, Dr. Erdmann said that during the past fourteen months he had operated six times, with two deaths. One of these died of status lymphaticus twenty-four hours after the operation; the other case was a very severe one, necessitating the excision of ten inches of the ileum, and an end-to-end anastomosis. Children, as a rule, bore operation well.

Perinephritis in Children.—Dr. WISNER R. TOWNSEND of New York said the term perinephritis was used by most writers to describe an inflammation in the tissues surrounding the kidney. The condition was not of frequent occurrence. He reported six cases in children seen at the Hospital for the Relief of the Ruptured and Crippled during the years 1894–1903. In not a single one of these cases was the correct diagnosis made by the attending physician who first saw the patient; all were sent to the clinic to have either spinal or hip braces applied. Gibney and others state that an erroneous diagnosis was made in over 50 per cent. of the cases seen. Only in rare instances should any difficulty arise correctly interpreting the symptoms in a case of beginning perinephritis. After the abscess had formed, the diagnosis was usually very easily made. In most instances, the etiological factor was obscure. Among them he mentioned exposure to cold, a strain or sprain, a blow or fall on the side, constipation, excessive exercise, jarring of the body, etc. The secondary form might follow infection of any part of the body, and had been seen in all forms of kidney lesions, especially in pyonephrosis, pyelitis and stone in the kidney, or after operations on the kidney, ureter, bladder, or urethra. The first symptom of a primary perinephritis was usually pain, which might be very severe in character. It was most frequently felt in the region of the kidney, near the vertebræ. It might be mistaken for neuralgia or lumbago, or it might extend downward and simulate sciatica. As movement of the body tended to aggravate the pain, the spine was generally held rigid, and it was due to this fact that so many of these cases were mistaken for Pott's disease. As the disease was of an inflammatory type, chills or rigors, followed by fever and septic temperature were among the early symptoms. Constipation was the rule. The treatment should meet the indications. If seen early, rest in bed, laxatives, and mild stimulation were indicated. After an abscess had formed, prompt surgical interference was imperative.

Dr. JACOBI said that constipation was not only a symptom of this condition, but also an important factor in its causation, both in the child and the adult. In the latter the constipation was generally severe, and of many years' standing. He could recall only four cases of perinephritis in children.

Diagnosis of Enlarged Bronchial Lymph Nodes in Children.—Dr. ALFRED FRIEDLANDER of Cincinnati stated that the lymphatic glands constituted a filtration apparatus. Given the factors of rapid growth on the one hand, and of poorly developed powers of resistance on the other, it could readily be seen that the period of childhood must necessarily be accompanied by marked reactive irritation and inflammation of the entire glandular system. During this period the mucous membranes were prone to irritation, with resulting inflammation. This, together with faulty conditions of hygiene and development, not infrequently taxed the filtration system to its utmost capacity. From the nature of things, we should expect to find inflammation of the tracheobronchial glands to be enormously common. The three groups of these glands, the tracheal, the tracheobronchial, and the peribronchial, intercommunicated freely; they received the lymphatics of the trachea and bronchi, the lungs and the pleuræ, and were directly connected with the mesenteric lymphatic nodes. Simple adenitis of these glands was very frequently the only precursor of a far more serious tuberculous involvement. There could be no doubt that many cases of enlarged bronchial glands tended to recovery without subsequent tuberculous infection, but the danger of such infection was always present. One of the early symptoms suggestive of enlarged bronchial glands was the peculiar paroxysmal cough; this resembled the cough of pertussis, excepting that there was not crowing inspiration. The paroxysms were often very violent, and exhausting, and might end in vomiting. Dyspnœa on even slight exertion, without demonstrable cardiac lesion, was frequently present. The appetite was capricious; the child was not well-nourished, and usually anæmic. There might or might not be an afternoon rise of temperature. Hoarseness, more or less constant, was often noted. Listlessness was frequently one of the early symptoms noticed by the parents.

The Importance of an Early Aural Examination in Acute Diseases of Children.—Dr. JAMES F. MCKERNON of New York emphasized the importance of frequent otoscopic examinations during the acute diseases of children, so that the presence of any pathological condition might be early recognized and treated. Otoscopic examination in very young children was by no means

an easy matter to those not constantly practising it; in the first place, the specula used were often too large; secondly, the auricle was drawn upward, backward and outward, and in this way the major portion of the lumen of the canal was shut off, whereas if the auricle were drawn gently downward and backward the canal was opened and the deeper structures exposed. In many cases, upon inspecting the drum membrane, when middle-ear disease was suspected, the drum, while white and prominent, showed not the slightest vestige of congestion, but if its surface be brushed with a cotton-tipped probe, the white-looking drum would be replaced by a bulging, reddened, and angry-looking surface, which showed the true condition of the middle ear after the exfoliated epithelium had been brushed away. In other cases complicating exanthemata, the upper half of the drum membrane appeared normal save for a slight tinge of congestion along the superior border of Shrapnell's membrane, while the lower half, and particularly that portion of the drum corresponding to the tubal opening in the middle ear, looked lustreless, and had a grayish, mottled appearance. This showed that already the mucous membrane of the tube and that portion around the tubal entrance was swollen and pouring fourth a serous exudate which demanded an immediate evacuation through an opening in the drum if we wished to cut short the process and prevent the disease from attacking structures higher up. In young children suffering from the acute exanthemata, Dr. McKernon said he thought an aural complication should be looked for each day. In a large number of the cases there was no symptom pointing to an aural condition until after the damage had occurred, namely, a spontaneous rupture, with destruction of a portion of the drum membrane, which might easily have been avoided had otoscopy been practised frequently. Ear complications should also be looked for in acute gastro-intestinal conditions, pneumonia, grippe, acute follicular tonsillitis, and typhoid fever.

Dr. Herman Jarecky of New York City said that in connection with the acute exanthemata, children who suffered from adenoids were particularly liable to middle-ear complications on account of the imperfect drainage. In typhoid fever the ear complications were probably so frequently overlooked on account of the general apathetic condition of the patient. In any case in which the ears were involved, if there was any bulging of the drum membrane, it should be promptly incised. This operation was a simple one, and could be done by the general practitioner as well as by the specialist.

Dr. Samuel Walker of Chicago said that otitis media could simulate almost any disease of childhood. There was nothing more important in the treatment of children than the routine and thorough examination of the ear.

Dr. Samuel McC. Hamill of Philadelphia said that of seven cases of typhoid fever in his wards at the hospital, three were complicated by otitis media. In the majority of such cases that he had seen, the complication occurred almost at the point of the defervescence in the temperature.

Dr. Louis Fischer said that, according to his experience, the temperature in connection with middle-ear suppuration was peculiar, and a rather uncertain guide. So much so, that he had come to look upon it as not a very positive symptom of that condition, especially during the infectious diseases. He regarded irrigation and cleansing of the nasal cavities as a very important factor in the production of middle-ear disease.

Dr. S. W. S. Toms of Nyack, N. Y., reported an instance in which cleansing of the nose in a child that was suffering from purulent rhinitis was followed by a double otitis media.

Dr. Thomas S. Southworth of New York City said that a certain percentage of patients with infectious diseases would develop an otitis media, whether the nose was irrigated or not, and the number would probably be reduced rather than increased by carefully cleansing the nasopharynx, where absorption of infectious material was so apt to occur.

Dr. McKernon, in closing, said he never used a spray or douche in the nose or nasopharynx. In young infants, excessive secretions could be wiped out with a cotton-tipped probe; in older children the head could be held to one side, and the cleansing fluid gently allowed to run through the nose. In reply to a question as to whether he advocated paracentesis in every case of bulging of the drum, Dr. McKernon said that he did, and in a certain number of the cases he would make the incision without waiting for the bulging.

Some Physical Signs in Infants and Children Not Sufficiently Emphasized.—Drs. Samuel McClintock Hamill and Theo. Le Boutillier of Philadelphia presented this paper, which contained the results of a systematic examination of the hearts and lungs of infants and children in the Out-Patient Department of the Howard and Polyclinic Hospitals, of Philadelphia, and showed important variations in the anatomical structures in the child as compared with those in the adult.

The Management of Hernia in Infancy and Childhood, with Results of Operative Treatment.—Dr. William B. Coley of New York, in discussing the question of whether the treatment should be mechanical or operative, expressed the opinion that the truss should be tried up to four years of age; rarely after that. The truss should be applied as soon as the hernia was discovered, and worn day and night. In cases in which the truss failed to correct the hernia, or when strangulation occurred, or when the hernia was irreducible, or associated with hydrocele, an operation should be done without delay. In a case in which a truss had never been worn, and which was not seen until after the age of four years, the question of mechanical or operative treatment had to be decided according to the circumstances of the patient. An operation saved time, and the cure was more likely to be permanent in 4 per cent. of his cases; since that time it had been less than 1 per cent. Almost any operative treatment succeeded in children much better than in adults.

Chorea.—Dr. W. C. Hollopeter of Philadelphia said that the treatment of chorea which he had found most satisfactory was the hydropathic, which he described as follows: The child was placed in a bath at a temperature that would prove no shock or surprise to it. A temperature of from 90° to 98° F. was usually satisfactory. The child, when once placed in the bath, was entertained by the nurse or mother by placing some playthings or floating toys in the water. Draughts should be guarded against, and the temperature of the water should be maintained sufficiently high. The bath could be prolonged for one or two hours, and given twice daily, the whole body being submerged, excepting the head and neck. At least ten minutes of the time could be profitably devoted to gentle, superficial massage of the arms, legs and trunk. Dr. Hollopeter said he had treated forty or fifty patients by this method, with the result of shortening the duration of the attacks from three months to six weeks.

Diseases of Children Occasioned by Affections of the Nose: The Necessity for Recognition and Treatment.—Dr. Louis J. Lautenbach of Philadelphia stated that children were great sufferers from obstructions of the nostrils. They were very prone to diseased conditions affecting the nose, and occluding the passageway. The mischief thus occasioned was common, and unfortunately often very serious to the life of the child, as well as to its health. Along the respiratory apparatus, tonsillitis, pharyngitis, laryngitis, and particularly bronchitis and pneumonia were commonly so caused—in great part by the mouth-breathing. Stomach and intestinal disorders were frequent results of nasal disease. Nervous affections, and lack of mental and physical development were by no means unusual. General lack of vitality and that in-

definable something called a general cold were frequent resultants. Lack of development of the dental arches and irregularities in tooth formation, as well as placement could very often be traced directly to nasal disease; the widespread mischief thus caused lasting often throughout life. An impartial, unbiased examination would nearly always develop a satisfactory diagnosis. The connection between the secondary conditions and the primary cause might not at first be clear, but when once understood, the local and general treatment could generally be instituted harmoniously, and the effective results would more than repay for the difficulties encountered. Fortunately, nasal troubles in children were easily cured, as a rule.

A Study of a Cas Conjoining Myxœdema and Diabetes Mellitus.—Dr. AUGUST ADRIAN STRASSER of Arlington, N. J., read a most carefully prepared paper on this subject and presented a number of diet tables.

The following officers of the section were elected for the ensuing year: *Chairman*, Dr. John Lovett Morse of Boston; *Vice-Chairman*, Dr. William E. Darnell of Atlantic City; *Secretary*, Dr. J. Ross Snyder of Birmingham, Ala.; *Member of the House of Delegates*, Dr. W. C. Hollopeter of Philadelphia.

Books Received.

While the MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will be promptly made of their receipt under this heading, it must be with the distinct understanding that its necessities are such that it cannot be considered under obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

GOLDEN RULES OF ANÆSTHESIA. By Dr. R. J PROBYN-WILLIAMS. Series No. XIV. 48mo, 67 pages John Wright & Co., Bristol, England. Price, 1 shilling.

THE MEANING OF A MODERN HOSPITAL. By W. BRUCE CLARKE, M.A., M.B. OXON., F.R.C.S. 8vo, 47 pages. Longmans, Green & Co., London, England. Price, 1 shilling net.

THE ELEMENTS OF KELLGREN'S MANUAL TREATMENT. By Dr. EDGAR F. CYRIAX. 8vo, 506 pages. Illustrated. Muslin. William Wood & Co., New York. Price, $4 net.

RAILWAY AND OTHER ACCIDENTS WITH RELATION TO INJURY AND DISEASE OF THE NERVOUS SYSTEM. A BOOK FOR COURT USE. By ALLAN MCLANE HAMILTON, M.D., F.R.C.S. 8vo, 351 pages. Illustrated. Muslin. William Wood & Co., New York. Price, $3.50 net.

LECTURES ON CLINICAL PSYCHIATRY. By Dr. EMIL KRAEPELIN. Authorized translation from the German. Revised and edited by Dr. THOMAS JOHNSTONE. 8vo, 308 pages. Muslin. William Wood & Co., New York. Price, $3.50 net.

MEDICAL DIAGNOSIS: SPECIAL DIAGNOSIS OF INTERNAL MEDICINE. By Dr. WILHELM V. LEUBE. Translated from the sixth German edition by Dr. JULIUS L. SALINGER. 8vo, 1058 pages. Illustrated. Muslin. D. Appleton & & Company, New York.

BLOOD IMMUNITY AND BLOOD RELATIONSHIP: A DEMONSTRATION OF CERTAIN BLOOD-RELATIONSHIPS AMONGST ANIMALS BY MEANS OF THE PRECIPITIN TEST FOR BLOOD. By GEORGE H. F. NUTTALL, M.A., M D., Ph.D. Including Original Researches by G. S. Graham-Smith, M.A., M.B., D.P.H. and T.S.P. Strangeways, M.A., M.R.C.S. 8vo, 444 pages. Muslin. University Press. Cambridge.

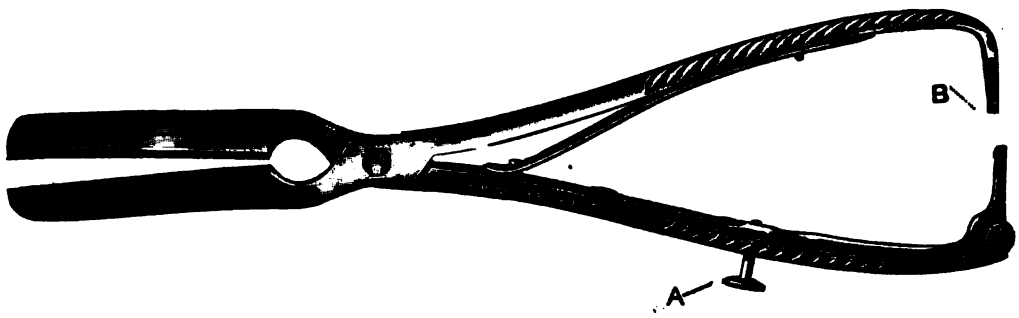
AMERICAN EDITION OF NOTHNAGEL'S PRACTICE. DISEASES OF THE INTESTINES AND PERITONEUM. By Dr. HERMANN NOTHNAGEL. Edited, with additions by Dr. HUMPHREY D. ROLLESTON. 8vo, 1032 pages. Illustrated, Muslin. W. B. Saunders & Company, Philadelphia, Pa. Price, $5 net.

New Instruments.

AN AUTOMATIC HEMORRHOID CLAMP.

BY MARTIN W. WARE, M.D.,
NEW YORK.

A NUMBER of hemorrhoid clamps exist, that seemingly fulfil our requirements, but they one and all call for the additional hands of an assistant to manipulate the screw that secures the blades. The greatest drawback to such an arrangement, therefore is, the multiplication of hands about the operative field.



To obviate this drawback is the object of this clamp devised. The construction permits of its being operated by one hand of the surgeon, the other being free for every other manipulation. The hemorrhoidal mass may thus be seized with the left hand, and the clamp applied to it. The pressure of the right operates the ratchet (B) at the head of the handles, and thus the blades are held securely. It is not intended that this mechanism should have the effect of the angiotribe, but merely to facilitate the application of the clamp, as ordinarily used heretofore.

The cauterization of the hemorrhoid completed, the pressure of the pin (A) in contact with the spring mechanism, releases the rachet, and the handles are forced apart with greater or less rapidity, dependent upon a relaxation in the grasp of the handles.

A clamp thus easily operated permits us to dispense with an extra assistant. Rapidity of operation and greater cleanliness are thus more easily obtained. The instrument can be taken apart and thoroughly sterilized,

1198 LEXINGTON AVENUE.

Splenic Anæmia.—J. H. Davenport and H. C. Pitts report a case of this nature, their patient being a girl of sixteen years. In addition to a severe anæmia she showed a mass rising from the right side of the pelvis to within about two inches of the navel, separate from and in front of the uterus. By vaginal examination it was movable and not tender. The greater part was on the right side, but it crossed the median line. It seemed probable that it was an ovarian cyst. An exploratory laparotomy was deemed advisable, and the mass was found to be the spleen with a long, slim pedicle. The viscus was not removed and the patient rallied well but died some two weeks later after a persistent vomiting of dark bloody fluid. In reviewing the literature, the authors note that the general consensus of opinion seems to be that early removal of the enlarged spleen gives the best hope of cure. Sippy has collected seven cases, which he thinks were probably ones of splenic anæmia and in which splenectomy was done. But of these seven, five apparently recovered entirely, while two died from hemorrhage. He makes the assertion that the mortality following splenectomy in this disease is much less than in leukæmia. Treatment with iron and arsenic sometimes gives marked improvement, and perhaps should be tried before resorting to operation.—*Yale Medical Journal.*

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending June 18, 1904:

	Cases.	Deaths.
Measles	652	15
Diphtheria and croup	375	50
Scarlet fever	190	16
Smallpox	...	...
Varicella	63	...
Tuberculosis	362	156
Typhoid fever	32	7
Cerebrospinal meningitis	...	53

The Early Diagnosis of Cirrhosis of the Liver, Considered from the Pathological Standpoint.—W. W. Ford has made a study of this subject based on a serious of 500 autopsies. In 49 of these cases, advanced cirrhosis occurred as the direct or accessory cause of death. Sixteen of these cases are directly associated with chronic interstitial nephritis, with secondary hyperthrophy and dilatation of the heart; 8 are associated with pure cardiac insufficiency, without renal complications. The majority of the 49 cases are examples of atrophic cirrhosis. Over 50 per cent. are definitely associated with arteriosclerosis. Next in point of frequency to the cases of atrophic cirrhosis, come the cases of syphilitic cirrhosis of the liver. Out of the whole series, only 2 can be considered hypertrophic in character. Parenchymatous degeneration of the liver cells occurred in 26 cases. Fatty degeneration was found in 158 cases. With a few exceptions, the cases of beginning cirrhosis of the liver are associated with renal disease, cardiac affections, and arteriosclerosis. The writer in referring to the attempt to solve the ultimate problems of this disease, calls attention to the triad of deities which Olsen would hold responsible for arteriosclerosis, Mars, Vulcan, and Venus.

A Study of the Condition of the Upper Air Passages Before and After Intubation of the Larynx. Also, an Inquiry into the Method of Feeding Employed in the Cases.—Louis Fischer presents the results of his studies of a series of cases of intubation. Not one of these cases had a normal throat at the time of intubation. Adenoid vegetations, enlarged tonsils, and chronic rhinopharyngitis were met with in almost every case. When the danger of diphtheritic laryngeal stenosis in a child is considered, it is important, if possible, to restore normal conditions in the rhinopharynx. Greater attention should be bestowed on the nose, as the most fatal cases are those of nasal diphtheria in which general sepsis follows. It is interesting to note that all of the children in this series that recovered had been breast-fed. This form of feeding must have had an important bearing on their bony development as well as their muscular structure. No chronic cough was encountered which could be attributed to the wearing of the tube. Comparing an equal number of children who never suffered with diphtheria nor were intubated, of the same age and development, it was found that they suffered with pneumonia and other infectious diseases in the same proportion as the children in this series. The larynx showed a tolerance for the tube for many weeks. One of these patients wore a tube twenty-six days, another twenty-five days. A properly fitting tube constructed of rubber leaves no evidence of chronic inflammation directly traceable to the tube, nor could any case be found in which the origin of catarrh was due to this cause. Although many of these children were decidedly rachitic, no deformity of the chest due to imperfect oxygenization could be attributed to the effects of the intubation tube. If children's throats are in a normal condition the risk of infection is reduced to a minimum.—*Archives of Pediatrics*, February, 1904.

A New and Simple Method for Obtaining the Sputum in Children.—Leonard Findlay describes a method of obtaining the sputum in children as follows: With a piece of gauze on the forefinger, the pharynx, and especially the epiglottis, is irritated so as to induce coughing, and any expectoration that is coughed up is swept out of the mouth with the finger before it has time to be swallowed. The quantity obtained varies. Several attempts may be necessary. The writer has had gratifying results with this method. He believes that this procedure has not previously been described in English.—*Archives of Pediatrics*.

Health Report.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, U. S. Marine Hospital Service, during the week ended June 18, 1904:

Abdomen, association of surgical lesions of the upper, 945; gunshot wounds of the, 319, 353; instrument in the, after operation, 927; laparotomy for gunshot wounds of the, 74; palpation of the, in the warm bath, 771; perforating wounds of the, 668; some deceptive conditions in the, 351.

Abdominal cancer, cytodiagnosis in, 749; cavity, direct illumination of the, for diagnostic purposes, 120; closures, one thousand, without a hernia, 231; disease, the costal arch in, 745; organs, behavior of the costal arch in diseases of the, 235; pain, 195; pain from irritation of the internal inguinal ring, 794; pain in pleurisy and pneumonia, 576; pain in pneumonia, 466; pain in rheumatism, 896; surgery in young children, 251, 274; surgical disease, some forms of chronic, 227; traumatism, cases of, 134; troubles, early operations in, 130.

Abortion, instruments for the production of, sold in the market places of Paris, 171; missed, rapid fetal maceration following, 109.

Abscess, hypophosphites in the prevention and treatment of, 40; recurrent intraabdominal, accompanied by unusual lesions in the mouth, 556;

Accouchement forcé, difficulties and dangers of, 987.

Acetonæmic vomiting in pregnancy, 590.

Acetonuria in mammary cancer, 151.

Acholia, early symptom of, 268.

Achylia, hydrochloric acid in, 469; intestinal conditions associated with, 972.

Acne, staphylococcus serum in, 828.

Actinomycosis, inflammatory epithelioma resembling, 430; in man, 110; (or osteomyelitis) of the femur, 188; primary, of the skin, 151.

Adams-Stokes syndrome, case exhibiting the, 1017.

Addison's disease, forms of, 798.

Adenitis, axillary and mammary adenoma, 934; cervical, operation for, 756; treatment of cervical, 389.

Adenoids, remote sequelæ of, 288.

Adler, I., heart syphilis, 281.

Aërophagia, clinical importance of, 348.

Agraphia, 195.

Air, dry superheated, in therapeutics, 404; liquefied, 93.

Air-passages, foreign bodies in the, 585, 590, 935.

Albany Hospital, surgical cases at the, 195.

Albany Medical Annals, jubilee number of, 99.

Albumosuria, myelopathic, 710, 989.

Albumins, ultramicroscopical examination of, 69.

Albuminuria, cyclic, 69; functional, 61, 227; non-nephritic renal, 379; opotherapy in, 259; physiological, 748; postural, 150.

Alcohol, artificial, 174; discussion of the question of, 889; dressings, 429;

Alcoholism, ergot in, 427; hypnotism in the treatment of chronic, 739; treatment of, 587.

Alibert's disease, 428.

Aliens, dirt, and disease, 1047.

Alkaline solutions. germicidal action of, 576.

Allen, Charles Warrenne, high frequency currents in the treatment of skin diseases, 285.

Allen, Horace Newton, U. S. Minister to Korea, 304.

Allis inhaler, a modified, 159.

Alopecia areata, traumatic, 430; congenita familiaris, 376.

Altshul, H., is iodide of potassium a specific in lobar pneumonia? 481.

Amaas, 827.

Ambidexterity, physiology of, 737.

Ambulances in London, 820.

American Dermatological Association, officers of the, 1012.

American Gastro-enterological Association, officers of the, 1050.

American Medical Association, officers of the, 1020.

American Surgical Association, officers of the, 1049.

Amœba coli, life cycle of, in the human body, 349.

Amputation, primary quadruple, 390.

Anæmia, antistreptococcus serum in pernicious, 333; fatty degenerative changes in, 174; infantum pseudoleukæmica, 144; infective splenic, 1019; pernicious in relation to gastric digestion, 980; pernicious, spinal cord changes in, 671; splenic, 796, 1065; splenic, of infants, 424.

Anæsthesia by sterile water, 187, 1056; general, two advantageous procedures in the induction of, 267; local, 231; mixed, 52; morphine-scopolamine, 69; necessity of a sign of complete, 389; nitrous oxide and oxygen for prolonged, 310; primary, 551, 944; spinal, 711; spinal, by repeated injections through a permanent opening in the spinal canal, 930; subarachnoid injections to induce, in renal and prostatic surgery, 279.

Anæsthetics, reforms needed in the administration of, 220.

Anderson, John F., remarks on the preparation of vaccine virus, 415.

Aneurysm, Addison's disease complicating, 829; aortic, 829; diagnosis of thoracic, 524; of the innominate, 1061; the Matas treatment of, 979; traumatic common-femoral arteriovenous, 553.

Angina pectoris, treatment of, 279.

Angioma cavernosum of the trapezius muscle, 789.

Anguillulosis intestinalis, 670.

Animal diseases in the Philippines, 465

Ankylostomiasis, 468, 933.

Ankle-joint, osteoplastic amputation at the, 555.

Anthrax, infection of a compound fracture by, 746; relations of the bacilli of, to the endothelial cells of mice and guinea-pigs, 188.

Antibodies, formation of, after injection of zymose, 70.

Antiseptic toilet for the hands and vulva, 170.

Antitoxins, action of, in the living organism, 971; manufacture of, in Chicago, 223; rashes, theory of, 18.

Aphasia, 195.

Apostoli treatment, 849.

Appendicitis, 149; abnormal location for the lesion in, 789; acute, 549; cases simulating, 240; conservative treatment of acute, 970; deceptive signs of improvement in septic, 150; epidemic of, 261; fecal fistula following, 353; from the standpoint of a physician, 977; in children, 274, 685, 716, 1025; increasing frequency of, 188; inflammation about a Meckel's diverticulum simulating, 673; influenza causing, 1061; in the China fleet, 904; mortality of, 108; obstruction and consequent distention the cause of, 548; Ochsner treatment of, 509; practical points relating to, 350; prenatal, 749; prevention of, 216; pseudo-, 746; recovery from, without operation, 599; retroperitoneal infection from, 389; simulated by a subcutaneous painful tubercle, 934; specimens of, 115; symposium of, 73; syphilitic, 829; treatment of acute, 120.

Appendicular abscess between the layers of the mesentery, 71; in the rectovesical pouch, treatment of, 390.

Appendiculo-ovarian ligament, clinical experience with the, 982.

Appendix, adenocarcinoma of the, 555; fish-bone abscess in the, 1056; hernia of the, 596; perforation of the, in typhoid fever, 667; removal of the, when the abdomen is opened for other purposes, 1025; Soule's method of burying the stump of the 709.

Appetite juice, 430.

Argyll-Robertson pupil, anatomical basis of the, 189.

Army, medical officer of the, as a sanitarian, 699; medical service of the, 844; proposed remodeling of the medical service of the, 577, 582, 706; reserve medical corps for the, 384; Russian, pay of medical officers in the, 852; surgeon, some duties of the, 302.

Arsenic, habituation to, 109.

Arterial degeneration, importance of treatment in the early stages of, 534; tension, low, 1016.

Arteries, resection of, and end-to-end union, 158.

Arteriosclerosis, blood-pressure determination in, 589; clinical studies in, 793; dietetic treatment of, 310; discussion on, 463; early diagnosis of, 68; early visceral changes in, 477; etiology of, 467; in relation to diet and the digestive system, 1017; symposium on, 985.

Arthritis from streptococcus infection, 798; deformans, 1061; infectious, 667; pneumococcic, 16.

Arthropathy of syringomyelia, 230.

Ascites cured by potassium iodide, 149; epiplopexy for, 426; in hepatic cirrhosis, 394; one hundred and fifty tappings for, 587.

Aseptic surgery in theory and practice, 390.
Asphyxia, traumatic, 790.
Association of American Medical Colleges, offices of the, 1050
Asthenopia, 193, 826.
Asthma, 469; spasmodic, 776, 835; treatment of, 341, 638; treatment of, by intratracheal injections, 502.
Atherton, A. B., two cases of abdominal traumatism, 134.
Axillary plexus, surgical lesions of the, 979.
Azotometer, an improved, 351.

B

Bacillus aerogenes capsulatus, infection with the, 587; pyocyaneus, intracellular toxin of, 708.
Bacteria, preparation of specific substances from, 228.
Bacterium coli, special type of infection by, 1058.
Baldwin, William W., some personal observations and experience of the Schott treatment of heart diseases, 241.
Ball, James Moores, concerning the lacrymal dilator, 107.
Banti's disease, malaria simulating, 515; splenectomy for, 231.
Bardes, A. C., running ear, 369.
Barkan, Louis, exercise in relation to diabetes, 960.
Bashore, Harvey B., our rural water supplies, 535.
Bath, radium in the waters of, 142.
Bath, the hot, 326.
Beck, Carl, a question of priority, 1054; the medicolegal aspect of accidents caused by the Röntgen rays, 288.
Bellevue Hospital, conditions in, 699; portable pavilion at, 663.
Bence-Jones albumin in a pleuritic effusion, 71.
Benedict, A. L., disinfection of car closets, 894.
Berg, A. A., the present status of the surgical treatment of chronic Bright's disease, 992.
Beriberi, etiology of, 30.
Berlin, letters from, 146, 184, 586, 1013.
Bicycle, therapeutic value of the, 148.
Bier's venous congestion, 1044.
Biggs, Hermann M., preventive medicine; its achievements, scope, and possibilities, 954.
Bile-ducts, cancer of the, 79; morbid conditions of the, 479.
Bilharzia hæmatobia, infection by, 918.
Biological research, limitations of, 18.
Birth, course of, with giant children, 176.
Birth rate in Germany, 480; in Great Britain, 460.
Bishop, Louis Faugères, importance of treatment in the early stages of arterial degeneration, 534.
Blackwater fever, 539, 828.
Bladder, cystoscopic appearance of, in health and disease, 609; early diagnosis of tuberculosis of the, 748; internal treatment of diseases of the, 388; irritability of the, 193; removal of papilloma of the, 702; tumors of the, 111; ventral suspension of the, 932.
Blair, Louis E., a case of recurring membranous stomatitis associated with erythema exudativum multiforme (Hebra), 729.
Biasucci, E., dilation of the bladder in suprapubic cystotomy, 454.
Blood, biological test for, 1005; differentiation of human and other mammalian, 429, 588; disorders of the, 1012; glycogen reaction in the, 710; mitosis in circulating, 816; testing the, 630.
Blunt hook, use of the, 336.
Boldt, H. J., new table designed for physicians office use, and particularly adopted for pelvic work, 439.
Bone-grafting, 432.
Bones, diagnostic value of x-rays in certain diseases of, 907; iodoform mass for filling cavities in, 736.

Book Notices:

Air, food, and exercises, by A. Rabagliati, 899.
Anatomie dentaire, par J. Choquet, 936.
Anatomy applied to medicine and surgery, by D. E. Mundell, 272.
Anatomy, atlas of human, second and third sections, by Carl Toldt and M. Eden Paul, 750.
Appendicite, diagnostic de, par Maurice Auvray, 937.
Asthma in relation to the nose, by A. Francis, 352.
Auges, Funktionsprüfung des von O. Schwarz, 232.
Bacteria, textbook of pathogenic, by Joseph McFarland, 592.
Biographic clinics, Vol. II, by G. M. Gould, 552.
Blood-pressure in surgery by G. W. Crile, 232.
Blues (splanchnic neunasthenia), by Albert Abrams, 471.
Brains and spinal cords of two brothers dead of hereditary ataxia, by Lewellys F. Barker, 471.

Bronchitis, infantile, 267; treatment of, in children, 598.
Bronchopneumonia in children, 315, 598, 745.
Bronchoscopy, 576.
Bronchus, foreign body in the, for ten years, 590.
Bryant, Bertram L., two cases of splenomedullary leukæmia, treatment and recovery, 574.
Bubo, climatic, 823.
Buildings, high, and physical degeneracy, 924.
Bull, William T., resignation of, from the chair of surgery in Columbia University, 615.
Bureau of Animal Industry, annual report of the, 138; medical relations of the, 1020.
Bureau of Chemistry of the Department of Agriculture, medical relations of the, 1021.
Burt, Stephen Smith, diagnosis of acute lobar pneumonia, 14.

C

Cabot, Follen, a simplified irrigating cystoscope for observation and ureteral catheterism, 519.
Cæcum, concretions in the, 389.
Cæsarean section, vaginal, 376, 551; 1044; vaginal, in eclampsia, 411.
Cancer, Adamkiewicz's serum in, 111; alleged curability of, 452; a new cure for, 344; behavior of, within nerve and trophic areas, 30; cardiac dulness in, 669; carotid extirpation for, 978; communicability of, 110; corset as a factor in the production of, 630; diagnosis of gastric, 670; early diagnosis of uterine, 33; etiology of, 268, 420; failure of Schmidt's treatment of, 350, 461; gastric, reduced cardiac dulness in, 585; implantation of, into the brain, 656; in Australia, 500; intestinal, 35; investigation of, 299; latest views on, 98; long lactic acid bacilli in the urine in a case of gastric, 575; malaria in relation to, 459; mammary, results of ovariotomy for, 227, 1056; nature of, 388; new symptom of œsophageal, 391; origin of, 23; parasitic theory of, 30; plea for early diagnosis of uterine, 746; radiotherapy in, 411; radium in, 710, 739; report on research-fund investigation of, 893; serum diagnosis of, 391; serum, unfavorable report on, 23; specific treatment of, 390; study of, in Great Britain, 921; transmissibility of, 350, 1006; treatment of, 30, 476; treatment of, by its own toxin, 194, 1005; *x*-rays for, 229, 935
Canteen, arguments in favor of the army, 80.
Canton, Ohio, Medical Society, officers of, 222.
Carbolic acid, poisoning by, in an infant, 827
Carcinoma basocellulare, 1016.
Cardioptosis, 511.
Cardiospasm pathology and treatment of, 228.
Cardiosplanchnic phenomena, 271.
Carnegie Institution, 976.
Carotid artery, ligation of the common, 438.
Carter, H. R., mode of infection of tuberculosis, 309; some characteristics of Stegomyia fasciata which affect its conveyance of yellow fever, 761.
Carter, William Wesley, thymic tracheostenosis, with report of a fatal case, 529.
Cataphoresis, 960.
Cataract extraction, ligation of the lacrymal duct to prevent infection after, 628; without iridectomy, 903.
Catarrh, epidemic, on shipboard, 399.
Catgut, Claudius's, 230; sterilization of, 826.
Cerebrospinal fluid, examination of, in the diagnosis of nervous disease, 1018; lymphocytosis of the, 125.
Cerebrospinal meningitis, 794; health-board diagnosis of, 890; epidemic of, 970; intraspinal injection of lysol in, 633; staphylococcus, 111; treatment of, by intraspinal antiseptic injections, 910.
Cervix, invasion of surrounding tissue by cancer of the, 981; time for repair of lacerations of the, 548.
Chancre, after-history in a case of extragenital, 29.
Charities Aid Association, annual report of the, 303.
Chest, gunshot wounds of the, 319; palpation of the, 395.
Chicago, sanitary progress in, 1010.
Chickenpox, smallpox concurrent with, 67.
Child, demands of the, by virtue of right, 982.
Child-labor, 963.
Chlorate of potassium and iron mixture, chemical and physiological action of the, 1043; danger of, 708, 1058.

Chlorine, antiseptic use of, 67.
Chloroform massage of the heart for collapse from, 636; prevention of accidents from, 39.
Chloroma with leukæmia, 795.
Choked disk in cranial contusions, 469.
Cholecystectomy, 347.
Cholecystitis, 158, 1059; acute traumatic, 268.
Cholecystostomy, 347.
Cholecystotomy for acute post-typhoidal infection of the bile-channels, 428.
Choledochotomy for impacted calculi, 354.
Cholera in the Philippines, 617; intensity of amboceptor formation in, after alcoholic intoxication, 551.
Chorea, 1064; eleven cases in one family, 748; sudden death in, 829.
Chorio-epithelioma malignum, 982.
Church, W. F., local applications in pneumonia, 775.
Cincinnati Academy of Medicine, officers of, 461; Research Society, officers of, 179.
Circulation, action of light baths upon the, 789.
Cirrhosis of the liver, early diagnosis of, 1066; early manifestationsof, 181; opotherapy in, 551.
Clark, L. Pierce, the surgical treatment of facial palsy, with the technique of faciohypoglossal nerve anastomosis, 321, 353.
Clarke, Floyd S., the early diagnosis of pulmonary tuberculosis, 55.
Claudius's catgut, 355.
Clavicle, complications of fracture of the, 828.
Coe, H. C., secondary laparotomy, 401.
Colitis, hypertrophic papillary, 755; treatment of mucomembranous, 788, 827.
Collapse, digitalis in, 709.
Collins, Joseph, spondyloze rhizomélique, 507.
Colon, acute and chronic circumscribed inflammation of the, 351; bacillus, differentiation of the, 70; congenital dilatation of the, 376.
Coma due to vesical distention, 350; malarial, 556; temperature in, 68.
Conjunctivitis, purulent, 398.
Consolidation of the medical societies in New York State, 103, 137, 190, 342, 557.
Constantinople, letters from, 145, 1015.
Constipation, habitual, 781, 818; in the infant, 1026.
Consultant, division of fees by the, with the general practitioner, 186, 225, 308, 346, 378; relation of, to the attending physician, 929.
Consumption, decrease of, in New England, 1009; prevention of, 380; rationale of the natural arrest of, 367, 393.
Consumptive, plea for justice to the, 1, 36; sanatoria for, 300.
Copper, poisoning by, 479.
Copra, poisoning by gas given off from, 465.
Corsets, cancer following irritation by the, 630; the curse of, 616.
Cordier, A. H., gallstones in the common duct, 723.
Cornea, ulceration of the, due to nasal infection, 629.
Corning, J. Leonard, intraspinal injections; the making of a permanent way through the bony wall of the vertebræ to facilitate their repetition—spinal anæsthesia produced in this way, 930.
Coronary arteries, sclerosis of the, 1019.
Correspondence, Berlin, 146, 184, 586, 1013; Constantinople, 145, 1015; London, 24, 66, 106, 144, 184, 224, 265, 306, 345, 387, 424, 463, 505, 544, 584, 625, 665, 705, 743, 783, 823, 893, 927, 967, 1012, 1052; Manila, 25, 307, 425, 464, 627, 785, 824, 967, 1052; New Zealand, 27, 1014; Paris, 929; Vienna, 928.
Corrosive sublimate, poisoning by, 790.
Costal arch, behavior of the, in diseases of the abdominal organs, 235.
Country doctor, honors to a, in England, 320.
Coxa vara, operative treatment of, 475.
Crane, Harold H., two cases of splenomedullary leukæmia, treatment and recovery, 574.
Craw-craw, 613.
Cremation, 420.
Cretinism, sporadic, 596.
Criminal, problem of the, 659.
Crippled, New York State Hospital for the, 382.
Crises, prostatic, 826; surgical value of the visceral, in the erythema group of skin diseases, 791.
Cross, Charles V., examination of the stools for solid bodies, 308.
Crutcher, Howard, five laparotomies on one patient, 535.
Cryoscopy, 438.
Cumston, Charles Greene, dentigerous cysts, 725.
Curettage, notes on, 1055.
Cyanosis, polycythæmic, 397.
Cystitis caused by the colon bacillus in infants, 934; treatment of, 816.
Cystocele, etiology and pathology of, with a new operation for its relief, 988.
Cystoscope, a simplified irrigating, 519; jubilee of the invention of the 383.
Cystoscopy, distention of the bladder by oxygen gas to facilitate, 468.
Cystotomy, suprapubic, dilatation of the bladder in, 454.
Cysts, dentigerous, 725; papilliferous, from an axillary gland, 669.
Cytodiagnosis, 70, 351; in nervous diseases, 121, 154; in tuberculosis, 474.
Cytotoxins, 663.

D

Dabny, Charles Whitney, president of the Cincinnati University, 102.
Dacryocystitis, modern treatment of, 527.
Dana, Charles L., cytodiagnosis in nervous diseases, 121, 154.
Darlington, Dr. Thomas, the new health commissioner, 63.
Deafness, treatment of, by ozone, 686.
Death, official, of living men, 825.
De Garmo, W. B., hernia in young children, 251.
Degeneracy, prevailing conception of, 186.
Delafield, Francis, some groups of kidney disease, 201.
Delirium grave, 800; prolonged, in acute heart disease, 986.
Dennett, D. C., radiotherapy, with report of cases, 253.
Dermatitis, x-ray, 440.
Dermatoses, general treatment of, 188; visceral manifestations of the erythema group of, 271.
Dessau, S. Henry, antiseptic treatment of pneumonia in infants and children, 250.
Deviation, term proposed in place of degeneracy, 186.
Diabetes insipidus, 794; in a child, 315; observations on, 720.
Diabetes mellitus, a case of, 895; a consideration of, 817; alcohol in, 266; diet in, 539; dietetic treatment of, 67; exercise in relation to, 960; glycolytic ferment in, 146; islands of Langerhans in, 220; myxœdema complicated with, 267; oats cure in, 885; pancreas transplantation in, 896; potassium iodide in, 628; treatment of, 360; symposium on, 191.
Diagnosis, new method of, in skin diseases, 1028.
Diarrhœa, bacterology of summer, 1027; infantile, Shiga bacillus in, 1027; streptococcus, 640.
Diazo reaction, simple method for carrying out the, 613.
Dickie, Perry, shall the consultant divide fees with the general practitioner? 225.
Diet of the poorer classes, 60.
Diphtheria, antistreptococcus serum in, 390; chronic, 933; epiphenomena of the antitoxin of, 189; nature and action of the toxin of, 470; paralysis of accommodation following, 427; prophylactic isolation of the carriers of bacilli in, 106; rashes following antitoxin injection in, 109; toxin and antitoxin of, 469; treatment of tracheotomy wounds in, 759; union of the toxin and antitoxin of, 972; use of antitoxin in, 656.
Disease, prevention of, 734.
Distoma felineum in man, 897.
Donnelly, James Francis, medical service in the merchant marine, 861.
Dock, George, prognosis; its theory and practice, 949.
Doctors, Mrs. Earle on, 420.
Drainage canal, contest over the Chicago, 222.
Drainage in surgery, 576.
Dreyfus, W. E., chemical and physiological action of the potassium chlorate and iron mixture, 1043.
Drinking, moderate, 426.
Dropsy, importance of, as a symptom, 587.
Drug habits, a suggested antinarcotic law to repress, 218; treatment of, 587.
Dum-dum fever, 380.
Duodenum, treatment of perforations of the fixed portions of the, 159; ulcer of the, 430.
Dyer, Isadore, is leprosy curable? 969.
Dysbasia angiosclerotica, 1018.
Dysentary, amœbic, 1060; and typhoid fever combined, 381; epidemic, 499; etiology of, 62; infantile, 1027; intestinal infection by the bacillus of, 596; late liver abscesses following tropical, 711; olive oil in, 467; serum treatment of, 897; toxin of, 429.
Dysmenorrhœa, spurious, 35.
Dyspepsia, nervous, 221.

E

Ear, bacteriology of suppuration of the middle, 16; dependence of affections of the, upon the nose and throat, 574; early examination of, in the acute diseases of childhood, 1063; extraction of foreign from the, 79; running, 369; scarlatinal parotitis, 173; side-effects of drugs on the, 550.
Eastern Medical Society, new quarters of the, 22.
East Side Physicians' Association, officers of, 180.
Eating, considerations regarding, 698, 702; ethics of, 430.
Eclampsia, modern theories of, 229; operative treatment of, 895; pathogenesis of, 1060; treatment of puerperal, 477; vaginal cæsarean section in, 411.

Eczema, staphylococci of chronic, 229.
Education, conflicting claims of general and professional, 192; medical, in London, 967; medical, in Manila, 627; medical, some aspects of, 976.
Eggs, poisoning by, 667.
Egypt, tuberculosis in, 510.
Ehrlich, Paul, Herter lectures by, 623, 663; visit of, to America, 581, 659.
Einhorn, Max, radium receptacles for the stomach, œsophagus, and rectum, 399; the serum treatment of typhoid fever, 81.
Eising, Eugene H., pathological distinctions discernible in the radiograph in certain diseases of long bones, 907.
Elbow, hemiresection of the, by internal lateral incision, 790; Thomas sling, for fractures at the, 76.
Electromagnet, therapeutic uses of the, 747.
Electrostatic bath, thermogenesis in the, 789.
Electrothermic clamps in the treatment of cancer of the uterus, 981.
Elephantiasis, treatment of, 256.
Ely, Leonard W., supplementary note on a case of typhoid spine, 655.
Emotional disturbances, treatment of, 226.
Emphysema, general subcutaneous, 111.
Empyema, 932; metapneumonic, in children, 467.
Encephalitis, acute, 432; œdematous, 32.
Endocarditis associated with pneumonia, 263; caused by the meningococcus, 302; from streptococcus infection, 798; malignant, with interventricular perforation, 276; pneumococcal, 1017; ulcerative, 896.
Endometritis, senile, 981.
Enteritis, tuberculous, perforation occurring in, 748.
Enterostomy, diaphragmatic, 269.
Enuresis, 191, 1027; in children, 969.
Eosinophile cells in sputum, 312; relation of, to bacterial infection, 795.
Epilepsy dependent upon unilateral ocular atrophy, 270; discussion on, 233; excision of cervical sympathetic ganglia in, 427; explosive character of attack, 827; eyestrain in, 594, 707; fracture of the base of the skull as a cause of, 895; method of arresting a fit, 971; nature of, 197; osteoplastic craniotomy for, 754; pathogeny and therapy, 590; prognosis of, 629; relation of, to chronic gastrointestinal disease, 186; seat of the convulsions in, 748; traumatic, 231.
Epileptics, mental condition of, 743.
Epithelioma, 186; inflammatory, 430.
Erdmann, A. F., a modified Allis inhaler, 159.
Erdmann, John F., strangulated hernia, 407.
Ergot in general practice, 1060; in surgery, 836.
Erythema nodosum in children, 983; scarlatiniforme, influenzal, 509.
Erythrocytes, origin of the basophilic granular, 351.
Erythromelalgia, 436.
Ethyl chloride, anæsthesia from, 39. 747.
Evans, Thos. R., pure whiskey, 346; therapeutic optimism, 224.
Exercise, relation of, to health, 187.
Exophthalmic goiter, surgical treatment of, 440.
Exophthalmus, mechanism of, 794.
Expert, the medical, 192.
Exudates, osmotic pressure of, 510.
Eyelid, sclerosing epithelioma of the, 590.
Eyes, choroiditis caused by excessive use of the, 297; circumcorneal hypertrophy of the, in the Negro, 591; complications in the, in Bright's disease, 348; congenital sarcoma of the orbit, 50; effect of radium on the, 631; examination of the muscles of the, 398; external diseases of the, due to rheumatism, 709; relation of effections of the, to organic diseases, 790; relation of the muscles of the, to the muscles of the rest of the body, 194; removal of foreign bodies from the, by the electromagnet, 1029; subconjunctival injections of alcohol in various affections of the, 839; warm medicated sprays in diseases of the, 27.
Eyestrain, 826; as a cause of headache and other neuroses, 787; effect of, on the nervous system of children, 1026; importance of the detection and relief of, 893; in epilepsy, 629, 707; mental and nervous disturbances produced by, 593, 707.

F

Facial anomalies, effects of, 897; atrophy, bilateral, 667; palsy, 311; palsy as a family disease, 268; palsy, surgical treatment of, 321, 353.
Fæces, examination of, for solid bodies, 308; significance of blood traces in the, 897; treatment of incontinence of, by paraffine injections, 509.
Fallopian tubes, obliteration of the, 111.
Fasting, therapeutic uses of, 896.
Fat necrosis, 28.
Fatigue, toxins and antitoxins of, 229.
Fee, the physicians, 141, 219.
Femur, new treatment for fracture of the neck of the, 441.
Fern, male, poisoning by, 469.
Ferrer, José M., treatment of pneumonia, 801.
Fever, differential leucocyte count in, 1060; metabolism in, 505.
Fibroids, Apostoli treatment of uterine, 894.
Fibrolipoma, retroperitoneal, 1024.
Ficker's typhoid reaction, 429.
Filaria in dog's blood, 70; perstans, mode of infection by the, 268, 382.
Filter beds, need of covering, 701.
Finch, Edward B., a case of Hodgkin's disease treated by x-rays, 773.
Fischer, Louis, some points on the diagnosis and drug treatment of pneumonia in infants and young children, 652.
Fistula, rectovestibular, in a baby, 757.
Flagella, methods of staining, 787.
Food, adulteration of, in Great Britain, 59; preservative, sulphurous acid as a, 931.
Forel, August, a statement by, 744.
Football injuries, 824.
Fractures, massage in, 133; new method of diagnosing, 298; of the femur from cancer, with bony union, 788; of the neck of the femur, new treatment for, 441; wiring of bone for, 629.
Fraenkel, Joseph, lymphocytosis of the cerebrospinal fluid, 125.
France, a "Drop of Milk" society in, 701.
Frank, Mortimer, congenital orbital sarcoma of endothelial origin; operation and preservation of the globe, 50.
Freudenthal, W., some points regarding the early diagnosis and some new features in the treatment of pulmonary tuberculosis, 409.
Fuller, Eugene, operative surgery applied to the seminal vesicles, 807.
Fulton, Henry D., the local use of quinine in hay-fever, 1054.
Furunculosis, staphylococcus serum in, 828.

G

Gall-bladder, acute flexion of the, as a cause of biliary colic, 107.
Galloway, C. M., iodide of potassium in diabetes mellitus, 628.
Gallstones, 1059; associated with septic cholangitis, 296; diagnosis and treatment of, 35; in the common duct, 723, 1025; in the common duct without characteristic symptoms, 136; specimens of, 835; surgical treatment of, 68.
Gangrene of the foot in a newborn child, 428; spontaneous, of hollow viscera, 776.
Garcia, Manuel, invention of the laryngoscope by, 502.
Gas, poisoning by illuminating, 793.
Gasserian ganglia, excision of the, for trigeminal neuralgia, 7.
Gastric juice, combined alkali and the titration of, 70.
Gastroenterostomy for carcinoma of the stomach, 455; twine in lieu of elastic ligature in, 1021.
Gastrointestinal troubles, massage in, 203.
Gastrosuccorrhœa, 749.
Gathmann, Henry, an unusual case of potassium iodide idiosyncrasy, 174.
General practitioner, disappearance of the, 660.
Germany, census of physicians in, 142.
Gibney, Virgil P., remarks on the management of fractures involving the joints, 43, 77.
Gibson, Axel Emil, the physiology of hunger, 374.
Gilliam, D. Tod, the question of priority, 786.
Glaucoma, adrenal extract in acute, 430; diagnosis and treatment of, 194.
Glandular fever, 151.
Gloves, combined rubber and cotton, 576; errors in the use of rubber, 554.
Glycolytic ferment, 69.
Glycosuria, diabetic and non-diabetic, in the same individual, 509; effect of saline solutions upon, 501, rapid gasometric test for, 351.
Goffe, J. Riddle, the physiological function of menstruation and the part played therein by the Fallopian tubes, 721.
Goiter, injections of iodized oil in, 312; surgical treatment of, 119.
Gonococcus metastasis, 587; sepsis, two cases of, 933; variability of the, 510.
Gonorrhœa, arterial thrombosis following, 29; in the puerperal state, 670; in women, 613; injection treatment of, 670; treatment of, by the general practitioner, 1062.
Gonorrhœal periarthritis probably due to inoculation through a wound, 815.
Goodwin, Wm. M., new instrument for Gilliam's suspension of the uterus, 944.
Gordon, Alfred, contribution to the study of spondyloze rhizomélique, with report of three cases, 247.
Gorton, Eliot, insomnia, 293.
Goulstonian lectures, 1012.
Goundou, relation of, to yaws, 279.
Gout, deficient urea excretion in, 604;

pathogenesis, of 151; relation of uric acid to the clinical manifestations of, 687, 712; treatment of, 269.
Gouty diathesis, treatment of the, 713.
Graft, medical, 396.
Gray, F. D., practical points on hernia, 211.
Griffith, Frederic, instruments for the production of abortion sold in the market places of Paris, 171; medical service in the merchant marine, 861; observations upon the protective value of the inspection of public women as carried out in Paris, 651; vacation for the doctor, 1054.
Grosse, Friedrich, a new female urinal, 38; the hot full-bath, 326.
Growth, impairment of, due to cerebral lesions, 477.
Gruening, E., orbital cellulitis; empyema of the ethmoid cells and the frontal sinus; abscess of the frontal lobe; pneumococcæmia; death, 215.
Grunwell, A. G., report of a case of kidney decapsulation, with some observations on the operation, 484.
Guinea-worm, life-span of the, 151.
Gunshot wounds, treatment of, in war, 318.
Guthrie, J. A., some observations while serving in the Philippines, 492.
Gynecology, local *vs.* general anæsthesia in, 708.

H

Hæmangioma, treatment of, 27.
Hæmatemesis from perforation of the œsophagus by a thoracic aneurysm, 276; treatment of, by gastro-enterostomy, 118.
Hæmatology, contributions to the study of, 789.
Hæmatoma of the sternocleidomastoid muscle, 335.
Hæmaturia in scurvy, 339, 897.
Hæmoglobinuria, 828; treatment of, 468.
Hæmolymph nodes, 671.
Hæmolysins of normal blood serum, 429.
Hæmopericardium, traumatic, 507.
Hæmoptysis, parasitic, 745; treatment of, 550.
Hæmostasis, temporary sutures for, 746.
Hæmostatic, a new, 1057.
Hallucinations of hearing, relation of unilateral aural disease to, 230; of vision, 149.
Hamadieh Hospital in Constantinople, 145.
Hands, antisepsis of the, 840; peculiar forms of infection of the, 700.
Harbin, insanitary condition of, 74.
Hartwig, Marcell, primary pyelitis in infants, 456.
Hassin, G. B., contributions to the Obersteiner-Redlich theory of tabes dorsalis, 168, 261.
Hay-fever, Dunbar's antitoxin in, 478; local use of quinine in, 1054; serum treatment of, 631.
Head, after-effects of injury to the, 468; bullet wounds of the, zone of hyperæsthesia of the neck after, 828.
Headache from eyestrain, 593; nasal, 426.
Hearing of school children, 963.
Heart, clinical signs of myocardial change, 911; determination of the functionating power of the, 1013; diastolic aortic murmurs with valvular lesions, 256; diastolic murmur in diagnosis, 787; disease of the, as an obstetrical complication, 987; disease of, due to abuse of alcohol, 657; effect of alternating-current baths on the, 898; effect of cold upon the, 828; effect of stimulants of the, on blood pressure in febrile conditions, 793; inception of the rhythm of, by the ventricle as the cause of continuous irregularity, 468; influence of altitude on diseases of the, 935; mopping out the boundaries of the, 228; massage of the, for chloroform collapse, 636; mitral and tricuspid stenosis, 986; movable, 511; musical murmurs of the, 228; nature's provision for stimulation of the, 548; new method of examination of the, 1057; pleural effusions in disease of the, 986; researches in hæmoglobin in chronic disease of the, 934; Schott treatment of disease of the, 241, 264; suture of the, 312; syphilis of the, 281; transposition of the, 514; treatment of failure of the, 268; valvular disease of the, 393, 395; vasomotor instability affecting the rhythm of the, 710.
Heat mechanism, action of certain agents on the, 160.
Heiman, Henry, multiple gonorrhœal periarthritis in a child, probably due to inoculation through a wound, 815.
Heins, G. L., the tuberculosis hospitals of the New York State hospitals for the insane, 601.
Hemorrhage, treatment of post-partum, 188.
Hemorrhagic diatheses, 148; septicæmia in animals, 660.
Hemorrhoids, automatic clamp for operation on, 1065; operative treatment of, 440.
Hepatic fever, parasitic, 470.
Hepatitis, acute diffuse, in syphilis 590.
Hernia, alcohol injections in cure of, 1007; congenital origin of, 509; epigastric, 746; in young children, 251, 1064; practical points on, 211; pulmonary, in a young child, 719; results of the Bassini operation for, 1058; rôle of the abdominal muscles in relation to, 160; strangulated, 407; treatment of, 816.
High-frequency currents in therapeutics, 49; in the treatment of skin diseases, 285;
Higley, Henry A., salaried positions open to medical men in the larger cities, 855; value of total and differential leucocyte counts during the course of typhoid fever, 495.
Hip-joint, amputation at the, for sarcoma, 35; congenital dislocation of the, results of the bloodless method of treatment of, 472; report on two cases of congenital dislocation of the, operated upon by Lorenz, 388; treatment of congenital dislocation of the, 36
Hodgkin's disease, 219; *X*-rav treatment of, 773.
Hospital-car, 237, 393, 732; for consumptives, 385.
Hospital Graduates' Club, annual dinner of the, 925.
Hospitals, funds needed for, 57; medieval, 260.
Hospital-ships, 341.
Huber, John B., the prevention of disease, 734.
Huddleston, John H., concerning the unrestrained use of the library of the New York Academy of Medicine by non-members, 707.
Humerus, dislocation of, by muscular action, 390; dislocation of the, complicating obstetrical paralysis, 475.
Humpstone, O. Paul, unusual sequela of a submammary hypodermoclysis, 216.
Hunger, physiology of, 374.
Hunt, J. Ramsay, acute infectious osteomyelitis of the spine and acute suppurative perimeningitis, 641, 672.
Hydrocele, of the cord, 1004; treatment of, 898.
Hydrocephalus, a case of, 748; drainage in, 757; surgical treatment of internal, 433.
Hydronephrosis, congenital, 829 intermittent, 148, 929.
Hydrophobia, strychnine in, 896.
Hydrosalpinx, 935.
Hymen, imperforation of the, 829.
Hyperphoria, tenotomy for, uncertainty of results in, 360.
Hyperpyrexia, a case of, 1041.
Hypnotics, use and abuse of, 895.
Hypodermic needles, how to cleanse, 203.
Hypodermoclysis, unusual sequel of a submammary, 216.
Hysteria, eyestrain in, 594; relation of, to the female genitals, 40.
Hysteroneuroses in women patients, 825.

I

Ileus, atropine in, 510.
Illinois State Medical Society, 892.
Immigrants, desirable, 20; exclusion of mentally defective, 462.
Immunity, contribution to the study of natural, 536; cytotoxic, 663; Herter lectures on, 623, 663; physical chemistry *vs.* biology in the doctrines of, 624; practical applications of, 280; the practical factor in, 1045.
Immunized animals, antitoxins and agglutinins in the blood of, 429.
India, census of, 1048.
Indiana State Medical Association, 891.
Indians, insanity among the, 63.
Indian Territory, medical practice law for the, 1010.
Inebriety, pathology of, 226; relation of, to mental disease, 780.
Infant-feeding, 666, 1048; best milk for, 1026; limitation of chemistry in, 709, 759.
Infantilism, 585.
Infants, caloric needs of premature, 671.
Infections, mixed, 551; rapidly consecutive, 437.
Inflammation, local anæsthesia for, 146.
Influenza, vitality of the bacillus of, in moist sputum, 1019; a cause of appendicitis, 1061.
Inhaler, a modified Allis, 159; a new anæsthetic, 760; modification of Bennett's, 757.
Injury, monetary value of an, 466.
Inoscopy, value of Jousset's, 510.
Insane, care of the, 382; reception hospitals for the temporary, 177; surgical operations on the, 358.
Insanity, action of the blood serum in, on the colon bacillus, 669; epileptic, treatment of, 108; isolation in the treatment of, 670; metaphysical conception of, 358; statistics of, 115.
Insomnia, 293; cure of, 699.
Insurance examiner, 853; ruling, a curious, 1049.
International Medical Congress, the next, 925.
Interstate Medical Journal, medical progress number of the, 180.
Intestinal anastomosis, new device for, 32; anastomosis, new method of, 226; anastomosis, simple method of, 467; exclusion, 532; neuroses, 631; obstruction caused by adhesions, treatment of, 149; obstruction, early diagnosis of acute, 549; obstruction following appendicectomy, 432; obstruction

in children, 1062; obstruction, post-operative, 227; obstruction, resection for, 75.
Intestine, significance of the normal bacteria of the, 151; strangulation of the, without perforation, 188; treatment of perforations of the fixed portion of the, 159.
Intubation of the larynx, condition of the upper air-passages before and after, 1066.
Intussusception, 827; in children, 274.
Iodide of potassium, administration of, 479; idiosyncrasy in relation to, 174.
Iodides, rectal administration of the, 275.
Iodine, non-toxic preparation of, 668.
Iris diaphragm, inventor of the, 336.
Iroquois memorial hospitals, 503.
Ischæmia, artificial, 391.
Italian immigrants, primitive types among, 700; public health relation of, 922.
Italy, foreign medical practitioners in, 536.

J

Jacobi, A., physicians prevented using the library of the Academy of Medicine, 546.
Jacoby, A., hydrocele of the cord; report of cases, 1004.
Jamaica, Santa Cruz Mountains in. for the tuberculous, 932.
Japan, movement of population in, 640.
Japanese Army, American nurses for the, 305; brain weight of the, 24; hospital ships, 615; manner of living of the, 962; navy, health of the, 301; soldiers, feet of the, 1048.
Jarecky, H., hemorrhage after tonsillotomy; its general consideration, 694.
Jaw, ankylosis of the, treated by wedge incision, 747; treatment of fractures of the lower, 550.
Jefferson Medical College, faculty changes at, 892.
Jejunostomy, method of, 704.
Jejunum, peptic ulcer of the, 784.
Jenkins Medical Association, 385.
Johnson, Alex. B., some operative methods for the fixation of movable kidney, and their results, 450.
Joints, management of fractures involving the, 43, 77.
Journal of Infectious Diseases, first issue of the, 100.

K

Kahler's disease 989.
Kentucky State Medical Association, 891.
Kidneys and skin, relative activity of the, 429; ascending infection of the, 400.
Kidneys, decapsulation of the, 309, 484, 747; decapsulation of the, from the pathologist's point of view, 237; diagnosis of contracted, 325, 357; diagnosis of the functional activity of the, 70; fused, 226; movable, in a child, 755; movable, operative fixation of, 450; renorenal reflex pain in, 746; significance of parenchymatous changes in the, 787; some groups of disease of the, 201; suture of the prolapsed, 231; tuberculosis of the, 708.
Kilmer, Theron Wendell, hæmatoma of the sternocleidomastoid muscle; a study of three cases, 335.
Knapp, Mark I., insufficientia pylori, 691.
Knee-joint adipose tissue in relation to disease of the, 979; floating cartilages of the, 553; lesions in structures surrounding the, 195; loose bodies in the, 157, 786; significance of the fatty tissue in the pathology of the, 550; tuberculous osteitis of the, 72.

L

Labor, chloroform in, 388; danger to the child during, 630; serious consequences of deep cervical incisions in, 312.
Labyrinth, etiology and treatment of suppuration in the, 350.
Lacrymal canal, congenital occlusion of the, 1027; dilator, 107.
Lactic-acid fermentation with reference to long bacilli, 31.
Lævulosuria as an index of hepatic disease, 1008.
Landry's paralysis, 787, 826.
Laparotomy, hernia in the scar following, 972; performed five times on one patient, 535; secondary, 401; technique of wounds incident to, 982.
Lapponi, Dr., and the Pope, 965.
Laryngectomy for epithelioma, 115.
Laryngitis, some phases of chronic, 193.
Larynx, intubation of the, condition of the upper air-passages before and after, 1537; lesion of the, in typhoid fever, 470; relief of hysterical manifestations in the, 148; tuberculosis of the, 831.
Lavage, the habit of, 108.
Lederer, William J., neuralgia due to dental irritation, 372.
Le Fevre, Egbert, uric acid and its relation to the clinical manifestations of gout and lithæmia, 687, 712.
Le Fevre, W. I., a radiographic surprise, 536.
Lefferts, George M., loving cups presented to, 542; minute of the Columbia Medical Faculty on the resignation of, 925.
Legal rights and obligations of the medical practitioner, 869.
Leishman-Donovan bodies, 970, 971.
Leprosy, a subcatabolic disease, 9; commission for the study of, 384; curability of, 780, 969, 1015.
Lesperance, Joseph, the soluble ferments of cow's milk, 447.
Leszynsky, William M., report of a case of brain tumor involving the right lateral ventricle, 165, 196
Leucocytes, glycogenic reaction of the, 430; neutrophile, in infectious diseases, 228;
Leucoplakia, relation of, to syphilis, 971.
Leukæmia, acute, with rupture of the spleen, 427; cure of acute lymphatic, 349; lymphatic, 676; pathology of, 389; splenic, 1056; two cases of splenomedullary. 574; x-rays in, 547, 895.
Life-insurance, relation of tuberculous glands to, 240.
Life, prolongation of, 178
Light, action of, upon the circulation, 789.
Lilienthal, Howard, a simple and accurate method of examining the stools for gallstones and other solid bodies, 56.
Limping, intermittent, 1018.
Lincoln, H. W., preliminary notes on transillumination of the stomach with fluorescein, 654.
Lipomatosis as a sign of degeneration, 1018.
Liver, acute yellow atrophy of the, 588; acute yellow atrophy of the, free amino-acids in the blood in, 710; cancer of the, 898; early symptoms of cirrhosis of the, 800; excision of a tuberculous mass from the, 613; extraction of a toxin from the cells of the, 708; gumma of the, 437; hepatectomy for tuberculoma of the, 667; lævulosuria as an index of disease of the 1008; malignant adenoma of the, 797; melanosarcoma of the, 276; method of approaching the posterior surface of the right lobe of the, 711; pericarditic pseudocirrhosis of the, 590; pulsating, 393; rupture of the, 636; surgery of the common duct of the, 681, 712; zonal necrosis of the, 797.
London, ambulances for, 820; letters from, 24, 66, 106, 144, 184, 224, 265, 306, 345, 387, 424, 463, 505, 544, 584, 625, 665, 705, 743, 783, 823, 893, 927, 967, 1012, 1052.
Long Island, climate of, 194.
Loomis Laboratory, legal decision regarding the ownership of, 543.
Louisiana State Medical Society, 892.
Ludwig's angina, 383.
Lumbago, 228; treatment of, 520.
Lumbar puncture, diagnostic value of, 121, 154.
Lung, cancer of the, 116; hemorrhages from the, 576; œdema of the, 150; primary cancer of the, 71; primary cancer of the, diagnose from the expectoration, 96; surgical treatment of abscess of the, 158.
Lupus, biniodide of mercury in, 1014; Finsen treatment of, 789.
Lydston, G. Frank, a nail in the deep urethra, 1042.
Lymphatic constitution, 576; system, surgical physiology of the, 33.
Lymphocytes, distinction of pseudolymphocytes from, 236.
Lynching, psychology of, 697.

M

Macalester, Richard K., the deficient urea-excretion in gout and lithæmia, 604.
McCormack, J. N., a plea for unification and uniform organization of State and County societies, 104.
McCormack Memorial Institute for Infectious Diseases, 973.
McGraw elastic ligature, experiments with the, 225.
McIntosh, W. P., gastroenterostomy for carcinoma of the stomach, 455.
McLaughlin, W. B., the rationale of the natural arrest of consumption; a study explaining the effect of sea voyages, out-door life, etc., on the disease, with suggestions as to ideal treatment, 367, 393.
Maggot, a parasitic, in the skin of an infant, 148.
Malaria, alleged transmissibility of the parasite of, from mother to child, 1017; campaign against, 381; cancer in relation to, 459; canine, 1005, followed by nephritis and neuritis, 149; irregular manifestations of, in an infant, 480; pathology of latent infection of 280; pernicious, 898; prevention of, 139; suppression of, on the Isthmus, 309; traumatism in relation to, 470; typhoid fever coin-

cident with, 1044; urticaria in, 150; when anopheles are absent, 59.
Malingering, diagnosis of, 45.
Malta, American hospital in, 1049; fever, chronic synovitis due to the organism of, 496.
Man, Isle of, as a climatic station, 834.
Mania, motor symptoms in, 468.
Manila, letters from, 25, 307, 425, 464, 627, 785, 824, 967, 1052; new general hospital in, 824; sanitary map of, 785.
Marie's disease, specimen from a case of, 477.
Marine Hospital laboratories, work of the, 1021
Mastoid and pre-auricular ganglia, semeiology of the, 790; process operations on the, 478, 638.
Mastoiditis, 414.
Mayo, William J., some observations on the surgery of the common duct of the liver, 681, 712; the association of surgical lesions of the upper abdomen, 945.
Measles, 678; diazo-reaction, Koplik's spots, and the temperature in, 312; enanthem of, 510; stage of invasion in, 68.
Medical Club of Philadelphia officers of, 141.
Medical Jurisprudence Society of Philadelphia, officers of, 180.
Medical practice laws, 873.
Medical services of the government and the profession, mutual relations and duties of, 984.
Medical societies of New York State, consolidation of the, 103, 137, 190, 342.
Medical Society of Alameda County, Calif., officers of, 180.
Melancholia, motor symptoms in, 468.
Meltzer, S. J., myelopathic albumosuria (Kahler's disease; multiple myeloma), 989.
Menière's disease, treatment of, 972.
Meningitis, cerebrospinal, see *Cerebrospinal*; new sign of basilar, 496; treatment of tuberculous, 268.
Menstruation, physiological function of, and the part played therein by the Fallopian tubes, 721.
Mental development, relation of physical defects to, 412; disease, relation of pathological conditions of the choroid plexuses to, 502.
Merchant marine, medical service in the, 861.
Mercer, Richard E., a new anæsthetic inhaler, 760.
Mercuric cyanide as a surgical disinfectant, 148.
Mesenteric vessels, thrombosis of the, 317.
Meyer, Willy, when and how shall we operate for prostatic hypertrophy? 1036.
Metrorrhagia with ovarian cysts, 511.
Microorganisms, ultramicroscopic, 776.
Midwifery, regulation of, in England, 618.
Migraine, treatment of, 340.
Milk, care of, as a food for infants, 17; dangers of improperly sterilized, 1047; destruction of pathogenic organisms in, by heat, 69; digestibility of, treated in various ways, 389; in infant feeding, 589, 1026; soluble ferments of cows, 447; stimulation of the secretion of, 351; supply in St. Louis, 518; supply of cities, 614; typhoid fever transmitted by, 900.
Milk-fever, treatment of, in cows, 966.
Milk-pox, Kaffir, 827.
Miner, Lucien L., tongue forceps, 78.
Miners' phthisis, 1008.
Mole, vesicular, of unusual size, 351.
Mongolian imbecile, deformity of the heart in a, 29.
Monster, double parasitic, 840.
Morris, Robert T., shall the consultant divide fees with the general practitioner? 225.

Oysters, infection of the sources of supply of, 687; typhoid fever transmitted by, 900.
Ozæna, paraffine injections in, 550.

P

Paget's disease, 153.
Pain, 346; abdominal, 195, 549; clinical significance of epigastric, 508.
Palate, pipe-smokers' ulcer of the, 776.
Panama, sanitary question on the Isthmus of, 267, 383, 458, 578, 680, 924.
Pan-American Medical Congress, the fourth, 1011.
Pancreas, calculi of the, 650; chemistry of the urine in diseases of the, 669; cyst of the, 116; diseases of the, 313, 625, 895; glandular cysts of the, 790; organotherapy in diseases of the, 828; pathology and surgery of certain diseases of the, 588; primary malignant disease of the, 710.
Pancreatitis, acute, 230, 423; islands of Langerhans in congenital syphilitic, 28.
Panotitis, scarlatinal, 173.
Paraffine, trophic and circulatory disturbances of the skin following injections of, 1019; use of hard or soft, for subcutaneous injections, 136.
Paralysis agitans, gymnastics in, 696; family periodic, 746; ischæmic, 240.
Paraplegia dolorosa, 436.
Paresis, general, early diagnosis of, 629.
Paris, bureau of information for students in, 422; letter from, 929.
Parotid region, enormous tumor of the, 903; tuberculosis of the, 613.
Parotitis following strangulated hernia, 29.
Parovarium, cyst of the, 430.

Patella, congenital absence of the, 933; recurrent dislocation of the, 426; treatment of fracture of the, 960, 1016.
Pathology, divorce of, from medicine, 501.
Peabody, George L., some thoughts suggested by the statistics of the Health Department, especially concerning typhoid fever and smallpox, 905, 938.
Pedersen, James, cases of urethral stricture and their management, 487.
Pelvic deformity, diagnosis and management of, 986; disease in the female insane, treatment of, 216
Pelvo-abdominal syndrome in women 470.
Pemphigus vulgaris, 668.
Pentosuria as a family anomaly, 1018.
Pepper, William, Thorpe's life of, 581.
Pepsin, new method of quantitative estimation of, 31.
Pericarditis, purulent, successful operative treatment of, 226; tuberculous, 1017.
Pericardium, drainage of the, 600.
Perinephritis in children, 1063.
Perineum, repair of lacerated, 427, 988.
Peritoneal exudates, formation and resolution of, 656.
Peritoneum, anatomy and physiology of the, 158.
Peritonitis, abdominal incision for tuberculous, 274; adhesive sclerosing, 157, 426; after appendicitis, operative results in, 788; diffuse septic, treated by the elevated head and trunk position, 193; enterostomy in, 894; pneumococcic, 269, 935; posture treatment of diffuse septic, 931; primary tuberculous, 673; treatment of, 158, 674.
Perityphlitis, early symptom in, 400
Perspiration, human, 311.
Peterson, Frederick, the tuberculosis hospitals of the New York State hospitals for the insane, 601.
Pharmaceutical societies, exemption of the property of, 460.
Pharynx, tuberculosis of the, 831.
Philadelphia County Medical Society, officers of, 180.
Philadelphia, milk supply of, 262; typhoid fever in, 890, 891.
Philadelphia Neurological Society, twentieth anniversary celebration of the, 261.
Philippines, infant mortality in the, 425; medical superstitions in the, 24; some observations while serving in the, 492; sanitary problems in the, 1052; surgical results in the, 745; see also *Manila*.
Phonendoscope, utility of the, 922.
Phototherapeutic lamp, a new and simple, 128.
Phototherapy by Tappeiner's method, 934.
Physiological subcommittee, reply to the, 889.
Piffard, Henry G., a few words concerning radium, 999; a new and simple phototherapeutic lamp, 128.
Pill habit in the United States, 178.
Pilocarpine in jaundice, tabes, and tetanus, 57.
Placenta prævia, 194; prævia, cæsarean section for, 745, 987; premature separation of the normally situated, 110; retention of, after abortion, 111; value of rubber gloves in the extraction of, 391.
Plague, a victim to laboratory, 179; fighting the, in Japan, 19; green, in Manchuria, 859; inoculation with prophylactic serum, 29; in South Africa, 702; in the Philippines, 161; prevention of bubonic, 896; sources of, 148; transmission of, 338.
Plants, chloroforming, 360.
Pleurisy, abdominal pain in, 576; prognosis of idiopathic, 466.
Pneumatic rubber suit, 75.
Pneumococcæmia, 215.
Pneumococcal endocarditis, 942; peritonitis, 935.
Pneumonia, 981; abdominal pain in, 466, 576, 970; and tuberculosis, relative importance of, to the community, 258; antiseptic treatment of, 250; contagiousness of, 709; determining factor in lobar and bronchial, 317; diagnosis of acute lobar, 14; etiology of acute, 178, 791; examination of the blood for pneumococci in, 507; in St. Louis, 305; local applications in, 775; meningeal complications in, 270; pericarditis, secondary to, 226; post-operative, 508; potassium iodide in, 481; prevalence of, 178, 179; senile, 467; transmission of, 101; treatment of, 310, 434, 801, 895; treatment of cardiac toxæmia in, 67; treatment of, in children, 598, 652.
Poe, Edgar Allen, as a dipsomaniac, 339.
Poisoners in the sixteenth and seventeenth centuries, 259.
Polish Medical Congress, 263.
Polycythæmia, chronic cyanotic, with enlarged spleen, 227.
Pomeroy, E. H., mastoiditis, 414.
Pond, Edmund M., early operations in abdominal troubles, 130.
Popliteal nerve, fibroma of the, 755.
Post-graduate period, 886; study of medicine, 841.
Potassium chlorate and iron mixture, 1043; chlorate, dangers of, 708, 1058; iodide, administration of, 509.
Pott's disease, scurvy simulating, 672.
Practitioner, passing of the general 778.
Precipitin reaction transmitted by inheritance, 469.
Pregnancy, early signs of, 348; extrauterine, 75, 107, 348, 666; following the removal of both ovaries, 1057; hydroelectric bath in, 590; in relation to tuberculosis, 109; laryngeal tuberculosis in, 832; pyelonephritis of, 935; recurrent tubal, 673; renal diseases of, 749; tetanus in, 790.
Prevarication, professional, 541.
Preventive medicine, 954.
Priestly, celebration of the one hundredth anniversary of the death of, 460
Pritchard, William Broaddus, a diagnostic syndrome for intracranial syphilis, with remarks upon prognosis and treatment, 769.
Prize, Lenval, 222.
Prognosis, 949.
Prostate, hypertrophy of the, 32; operation for hypertrophy of the, 708; surgical problem in hypertrophy of the, 230; treatment of senile hypertrophy of the, 112; use of the cystoscope in determining upon operation for hypertrophy of the, 745; when and how to operate for hypertrophy of the, 1036.
Prostatectomy, 157; suprapubic and perineal, 971.
Prostatic crises, 826.
Prostitutes, protective value of the inspection of, in Paris, 651.
Prostitution, regulation of, 901.
Protozoon, a new, 380.
Pseudoleukæmia, *x*-rays in, 547.
Psoriasis, external treatment of, 428.
Psychoses, hydrotherapy in, 548.
Ptomain poisoning followed by desquamation, 1056.
Public health and marine-hospital service, 850.
Puerpera, care of the, 827.
Puerperal eclampsia, treatment of, 630, 823.
Puerperal sepsis, antistreptococcus serum in, 928; formalin in, 1058; from animals, 935; iodine in, 187; operation for, 970; prevention and treatment of, 311; prophylaxis of, 653.
Puerperal septic infection, 463, 638.
Pulmonary disease, thorium emanations for, 550; embolism following phlegmasia alba dolens, 549; hernia, traumatic, 551.
Pulmonary tuberculosis, cardiac thrombosis in, 1019; condition of the blood in, 466; diagnosis of incipient, 496; early diagnosis and treatment of, 409, 669; human slavery in the prevention of, 1055; Marmorek's serum in, 961; pneumothorax in, 426; thrombosis of jugular veins in, 427.
Pulse, acoustic transformation of the, 109; changes in, due to stimulation of special senses, 1012.
Punton, John the principles of diagnosis of medical malingering, 45.
Pyæmia, chronic, 1018.
Pyelitis, primary, in infants, 456.
Pyelonephritis of pregnancy, 935.
Pylorus, congenital narrowness of the, a cause of gastric disease in the adult, 390; congenital stricture of the, 860; insufficiency of the, 191, 691; stenosis of the, in children, 275.
Pyonephrosis, retroperitoneal abcess simulating, 674.

Q

Quack, definition of a, 545.

R

Rabies, filtering the virus of, 30.
Radiographic surprise, 536.
Radiotherapy, 194; comparative value of different rays, 466; dosage of, 470; in cancer, 511; with report of cases, 253.
Radium, 356; action of, in cell division, 828; action of, on the eyes, 631; a few words concerning, 999; analgesic action of, 703; common sense regarding, 780; effects of, on animal life, 62; forecast of, in fiction, 580; in blindness, 542; in cancer, 99, 710, 739, 893; in rodent ulcer, 549, 747; in sarcoma, 715, 938; in the waters of Bath, 142; notes on, 931; rays, nature of, 30; therapeutic value of, 108, 146, 228, 266, 1013, 1057.
Radium-receptacles for the stomach, œsophagus, and rectum, 399.
Rafferty, H. N., a case of bilharzia hæmatobia infection, 918.
Rafferty, T. N. a case of bilharzia hæmatobia infection, 918.
Rahmi, Hanna Mikail, the Syrian climates, 736.
Railway employees, first aid instruction for, 621; property, necessity of the disinfection of, 888, 894; surgery, 859.
Ransom, J. B., the ordinary *x* and ultraviolet rays in the treatment of tuberculosis, 331.
Rays, violet and ultraviolet, 137.
Reading in bed, 19.
Rectal incontinence, 555.
Rectum, removal of colloid carcinoma of the, 75.

Recurrent fever in Gibraltar, 468.
Red blood cells, volume of, in various diseases, 500.
Red Cross Society in the East, 461; reorganization of the American, 782, 1051.
Reed Memorial Association, 964, 975.
Reflexes, diagnostic significance of, 8; in uræmia, 227.
Renal colic, pulsating pain in, 898; insufficiency, organotherapy in, 230.
Resorcin, action of, 786.
Respiration, acoustics of, 986; artificial, 66.
Rest treatment, inception of the, 358.
Resuscitation of animals apparently dead, 75.
Retina, symptoms of vascular degeneration in the, 349.
Revolution, treatment of gunshot wounds by British surgeons during the, 361.
Rheumatic infection, clinical aspects of, 428.
Rheumatism, abdominal pain in, 896; antistreptococcus serum in, 31; cases of apparent infection in, 68; diagnosis of, from the arthritides, 225; etiology of, 41, 887; infection in acute, 311; infection theory of, 184; infective nature of, 896.
Rheumatoid arthritis, the vision in, 387.
Rhinitis, curative effect of erysipelas on atrophic, 680; operation on deformed septa in atrophic, 107.
Rhinoplasty, a case of, 432; complete, from the arm, 551; new procedure in, 353.
Rickets, enlargement of the phalanges in, 310; etiology of, 696.
Rinderpest in the Philippines, 785, 824.
Ringworm, prevention of the spread of, 187.
Robertson, A. E., mixed anæsthesia, with special reference to the administration of hyoscine hydrobromate before ether, 52.
Robinson, Beverley, questions of uranalysis bearing upon the diagnosis of contracted kidney, 325, 357.
Robinson, Byron, the rectal segment of the ureter, 570.
Rockefeller Institute, 976.
Rockwell, A. D., x-ray dermatitis as influenced by idiosyncrasy, 92.
Rodent ulcer, radium treatment of, 549, 747.
Rogers, John, tetanus treated by intraneural injection of antitoxin, 813.
Röntgen rays, action of, on animals, 69; action of, on cell division, 828; apparatus for limiting the action of, 590; determining the position of the heart by the, 630; dermatitis caused by, 440; dermatitis from, influenced by idiosyncrasy, 92; diagnostic value of, in diseases of the long bones, 907; effect of, on the internal organs, 898; identification of criminals by means of, 78; immediate reaction after the use of the, 933; in cancer, 99, 229, 935; in glandular tuberculosis 226; in leukæmia and pseudoleukæmia, 547, 773; in sarcoma, 28; in splenomyelogenous leukæmia, 895; medicolegal aspect of accidents caused by the, 288; nature, application, and dermatological effects of, 87; nature of the, 398; pathological changes induced by, 628; production of electricity for field work in, 964; therapeutic uses of, 67; treatment of ulceration caused by, 1018.
Roosa, D. B., St. John, a dinner in honor of, 386; on a case of choroidal inflammation with permanent loss of vision, caused by excessive use of the eyes during a comparatively short period of time, 297; on the post-graduate study of medicine, 841.
Rosenau, M. J., the public health and marine-hospital service, 850.
Rötheln, new symptoms of, 226.
Rubber gloves, method of dispensing with the, 508.
Rush monument, unveiling of the, 1010.
Russian military medical service, 615.

S

Saddle-nose, celluloid plate for the correction of a congenital, 608.
Salaried positions open to medical men, 855.
Salicylic acid, poisoning by, 349.
Saline mineral waters, effect of, on metabolism, 656; solution, physiological, 548.
Saliva, 548; normal microbic flora of the, 470.
Salivary glands, mixed tumors of the, 575, 778.
Sanatoria for consumptives, 300; selection of cases for treatment at, 499.
Sanford, William W., the hospital car; its equipment, uses, and importance, 732; the railway surgeon, 859.
Sarcoma, clinico-statistical study of, 898; local and general relations of, 556; multiple, 671; nasal, 588; of the femur, hip and thigh amputations for, 521; prognosis of intestinal, 829; radium in, 715; x-rays for, 28.
Satterlee, Francis Le Roy, Jr., the Röntgen or tri-ultraviolet rays, their nature, application, and dermatological effects, 87.
Satterwhite, Preston, anæsthetized during sleep, 666.
Savidge, Eugene Coleman, the attending physician and consultants, 929; the unclassified troubles of women, 766.
Saxe, G. A. de Santos, the psychical relations of tuberculosis, 147, 506.
Scarlatina, antistreptococcus serum in, 390; associated with typhoid fever, 270; prevention of nephritis in, 159; protozoa of, 337; source of the infection of, 509; variations of weight during, 734.
Schley, W. Scott, the use of rubber tissue and boracic acid in the treatment of surface granulating wounds, and especially of the varicose ulcers of the leg, 915.
Schools, medical inspection of, 943.
Schott treatment of heart disease, 241, 264.
Schroeder, Aimée Raymond, resolutions on the death of, 582.
Schroeder, Henry H., the insurance examiner, 853.
Sciatica, carbon bisulphide in, 604; physical examination in, 656.
Scopolamine hydrobromate, uses of, 747.
Scott, R. J. E., State medical practice laws, 873.
Scurvy, hæmaturia in, 897, 1062; in infants, 976; observations on an unusual case of, 108.
Sea-air, effect of, 269.
Sea, life's elements in the, 662.
Seasickness, 108; etiology of, 613; etiology and treatment of, 68.
Seaside climate, effects of, on the nervous system, 111.
Seborrhœa nigricans, case of, 591.
Sebring, William C., what shall we do with the nervous woman? 564.
Seminal vesicles, surgery of the, 807.
Senility, mental disorders of, 298.
Sensibilitization, 711.
Sepsis, general, from wounds, 506; staphylococcus, 269.
Septic fever, obscure cases of, 348; wounds, care of, 708.
Serositis, multiple, 394.
Serum diagnosis, forensic uses of, 429; therapy, 894.
Sewage contamination, Bacillus coli communis as an indication of, 140.
Sheldon, John G., the technique of the removal of one-half of the thyroid gland, 573.
Shellfish, bacteriology applied to the examination of, 580.
Sherrington, Charles S., lecture on cerebral localization by, 781
Shiga-bacillus infection, 426, 467.
Ships, sanitation of, in the tropics, 739.
Ship-surgeons, 861; emoluments of, 20.
Shock, digitalis for, 709; temperature in, 231.
Shrady, George F., hip and thigh amputations for sarcoma of the femur, 521, 556.
Sigmoid flexure, tumors of the, 189.
Silver foil, prevention of adhesions in brain surgery by, 158, 508.
Simpson, William Kelly, appointed professor of laryngology at Columbia University, 421; dinner in honor of, 926.
Sinus, abscess of the lateral, 67; pericranii, 1057.
Sinusitis, frontal, 389; frontal and ethmoid, 215.
Skiagraphic errors, 629.
Skin, discoloration of the, following the administration of adrenalin, 351; diseases, sea-bathing for, 548; elasticity of the, 920; reflex eruptions of the, from urethra lesions, 27.
Skin-grafting, influence of, on the recurrence of morbid growths, 496.
Skinner, Clarence Edward, dry superheated air in therapeutics, 404.
Skull, fracture of the, 432; fracture of the, trephining in, 560.
Sleep, forced, 579; induction of anæsthesia during, 666; need of, 170; prolonged, 421.
Sleeping sickness, 60, 144; etiology of, 800; report on, 538.
Smallpox, aerial convection of, 459; antiseptic treatment of, 1056; antistreptococcic serum in, 533; carbolic acid in, 109; chickenpox concurrent with, 67; etiology of, 777; germ of, 22; in the Philippines, 967; isolation in, 818; means of diminishing, 497; nervous complications and sequelæ of, 591; thoughts suggested by Health Board statistics of, 905, 938.
Smith, Alfred C., antistreptococcic serum in the treatment of smallpox, 533.
Smith, Stephen, the treatment of gunshot wounds by British surgeons during the war of the Revolution, 361.
Snake venom, physiological action and antidotes of, 349.

Society Reports:

Speech defects, 951.
Spermatic cord, fibromata of the, 270.
Sphygmograph, prognostic value of the, 470.
Sphygmomanometer, a portable, 358; use of the, 786.
Spinal cord, action of corrosive sublimate on the, 230; diffuse (combined) degeneration of the, 27; operation in injuries of the, 791.
Spine, acute infectious osteomyelitis of the, 641, 672; forcible correction of lateral curvature of the, 586; fracture dislocation of the, 33; typhoid, 40.
Spitting nuisance, war upon, 421.
Spleen, multiple angiomata of the, 51.
Splenectomy, indications for, 110.
Splenomegaly, 796; parasitic bodies found in tropical, 269, 350.
Spondylitis, tuberculous, 718.
Spondylosis rhizomelica, 155, 247, 507.
Spoon, inaccuracy of the, as a measure, 508.
Spooner, Henry G., the bladder in health and disease, as demonstrated by the cystoscope, 609.
Spotted fever, 498.
Sprains, massage in, 133.
Spratling, W. P., appointed superintendent of Bellevue Hospital, 820; on eyestrain and epilepsy, 707.
Sputum, simple method of obtaining, in children, 1066.
Squires, G. W., a new sign of basilar meningitis, 496.
Stanwood, Edward, suppression of malaria on the Isthmus, 309.
Staphylococcus sepsis, 269.
State Boards of Health, conference of, 964.
State medical practice laws, 873.
Status lymphaticus, neuroses of the, 310.
Steapsin solution, antibody against, 510.
Sterility, 514; in the female, 270.
Stern, Heinrich, who is underfed? 811, 835.
Stewart, Douglas H., an antiseptic toilet for the hands and vulva, 170.
Stockton, George, the relation of physical defects to mental development, 412.
Stomach, cancer of the, 931; clinical value of an analysis of the contents of the, 276; congenital hour-glass, 828; diagnosis of cancer of the, 670; gastroenterostomy for cancer of the, 455; hour-glass, 345; lavage of the, without a tube, 103; operation for ulcer of the, in a woman past seventy years of age, 304; significance of minute quantities of blood in the contents of the, 31; surgical treatment of ulcer of the, 902; transillumination of the, with fluorescein, 654; treatment of cancer of the, 934; treatment of ulcer of the, 117, 227; ulcer and cancer of the, 668; ulcer of the, hot-water injections as a substitute for nutrient enemata in, 933; volvulus of the, 885.
Stomatitis, recurring membranous, 237, 729.
Stony Wolde Sanatorium, 22.
Stools method of examining the, 56.
Street locomotion in New York City, 889.
Stricture, treatment of urethral, 487.
Strike, physicians; in Leipsic, 1014.
Stumps, end-bearing, 553.
Subarachnoid injections for the production of analgesia, 430.
Sudoriferous glands, cancer of the, 511.
Sulphur baths, 894.
Suprarenal apoplexy, 971; extract, influence of, upon absorption and elimination, 792; gland, chronic inflammation of the, 189.
Surgery, blood-pressure observations in, 547; individual equation of the patient in, 508.
Suture, buried animal, 136.
Sycosis, staphylococcus serum in, 828.
Sympathetic, pathology of the cervical, 226.
Synovitis, chronic, due to the organism of Malta fever, 496.
Syphilis, 515, 558; a subcatabolic disease, 9; can the viris of, be filtered? 971; cardiac, 281; decline of, 586; experimental, 30; hereditary, in the second generation, 270; hereditary, tabes juvenilis in, 110; icterus in secondary, 819; inoculation of, in the ape, 110, 184; intestinal, 728; intracranial, a diagnostic syndrome for, 769; intramuscular injection of calomel in, 671; relation of leucoplakia to, 971; relation of the the Argyll-Robertson phenomenon in, 68; severe secondary, treated by intravenous injections of corrosive sublimate, 1019.
Syphilitic convulsions preceded by marked somnolence, 510.
Syria, climates of, 736.
Syringomyelia, arthropathy of, 230.

T

Tabes dorsalis, aneurysm and syphilis associated with, 589; arthropathies of, 672; early appearance of arthropathy in, 833; forensic eye aspects of, 508; juvenile, 787; juvenile, and hereditary syphilis, 110; Obersteiner-Redlich theory of, 168, 261; sodium cinnamate in, 548; syphilogenic theory of, 312.
Table for office use, especially in pelvic work, 439.
Tænia saginata, occurrence of more than one, in the same person, 151.
Taylor, Alfred S., the surgical treatment of facial palsy, with the technique of faciohypoglossal nerve anastomosis, 321, 353.
Taylor, Arthur N., legal rights and obligations of the medical practitioner, 869.
Teachers, mortality among, in the Philippines, 627.
Teeth, care of the soldier's, 963; influence of tropical conditions on diseases of the, 785.
Temperature, remarks on, 428.
Temple of Hygeia, an insanitary, 336.
Tenement-house inspection, 19.
Tenorrhaphy of the flexor tendons, 755.
Testis, cancer of a retained, 826
Tetanolysin, constitution of, 789.
Tetanus, acute, 971; antitoxin in, 319; cure of, 511; effect of the galvanic current on the toxin and antitoxin of, 510; intraneural injection of antitoxin in, 813; in pregnancy, 790; prevention of, 826, 1016, 1055; successful treatment of, 462, 468; toy pistol in the causation of, 318.
Tentany, a case of, 348; associated with mucomembranous colitis and phthisis, 509; association of, with chronic diseases of the stomach, 943.
Theater fire, lessons of the Chicago, 58.
Therapeutic optimism, 224.
Thermometer, disinfection of the, 970.
Thoracentesis, death following puncture of the lung in, 717.
Thorium, therapeutic possibilities of, 126.
Thread reaction, observations on the, 677.
Thrombosis of the mesenteric vessels, 317.
Thrush, 389.
Thyroid gland, cysts of the, 110; technique of removal of one-half of the, 573.
Thyroiditis, acute suppurative, 271.
Tibia, subluxation of the, 476.
Tick fever, 498.
Tissue-lymph circulation, 788.
Tongue forceps, 78.
Tonsils, amputation of the, with the cold snare, 711; the submerged, 192.
Tonsillitis, chronic, 298; tincture of iodine for acute, 120.
Tonsillotomy, hemorrhage after, 694.
Torticollis, treatment of, 271.
Tourniquet, pneumatic, in craniotomy, 548.
Toxin, action of fluorescent substances upon, 829; and antitoxin, mutual relations between, 623.
Toy pistols prohibited, 965.
Tracheostenosis, thymic, 529.

Trachoma, non-operative treatment of, 195.
Tracy, Samuel G., physicians prevented using the library of the Academy of Medicine, 507; the use of the library of the Academy of Medicine, etc., 666; thorium; a radioactive substance with therapeutic possibilities, 126.
Transillumination of the stomach, 745.
Treatment of disease by mental influence, 149.
Triangle, Grocco's paravertebral, 312.
Trichinosis, a case of, 632; cells with eosinophile granulation in, 671; epidemic, 1046.
Tri-State Medical Association of the Carolinas and Virginia, officers of, 740.
Tropical medicine, a diploma in, 422; work of the London School of, 23.
Trypanosomata, agglutination and filtration of, 797; cultivation of, 797, 931.
Trypanosomiasis, dyes as therapeutic agents in, 711; human, on the Congo, 269.
Tubercle bacilli, thermal death point of, in milk, 631.
Tuberculin, diagnostic value of, 429; uses of, 705.
Tuberculosis, administrative control of, 343; agglutination in, 747; and pneumonia, relative importance of, to the community, 258; antitoxin treatment of, 269; arctic treatment of, 709; articular and osseous, sunshine and fresh air *vs.* ultraviolet and *x*-rays in, 540; Behring's theory of infection, 589; bovine and human, 540, 753, 787, 926; clinic of the Board of Health, night sessions of the, 820; combat against, 391, 429; combat against, by communities without health departments, 1016; congenital, 657; cytodiagnosis in, 474; danger of infection of attendants, 825; demineralization in, 1057; diet in, 633; early diagnosis of, pulmonary, 55; early diagnosis of vesical, 748; exposition in Baltimore, 182; glandular, ichthyol in, 268; glandular, *x*-ray treatment of, 226; house infection of, 348, 923; human and bovine, 540, 753, 787, 926; immunization against, 30; in Chicago, 261; infantile, 752; intestinal, in children, 896; issue as a therapeutic measure in, 186; laryngeal, 831; latent, 737; Marmorek's serum in, 69, 665, 668; meningeal, treatment of, 268; mode of infection of, 309, 586, 752; nasal, 830, 928; national association to combat, 504; New York State hospital for the insane with, 601; observations on, in Marburg, 660; of the breast, 359; of the cervical glands, toxæmia in, 191; of the epididymis, 199; of the spinal cord, 629; open-air treatment of, in Chicago, 461; parotid, 613; paths of infection in 64; pericardial, 1017; pharyngeal, 831; pregnancy in relation to, 109; prevention of, 175; prevention of, in children, 753, 983; production of, 972; prophylactic value of garlic against, 150; primary peritoneal, 673; primary seat of infection in, 710; problems for the convalescent, 1062; psychical relations of, 147, 266, 506, 706; radiotherapy of, 331 relation between laryngeal and pulmonary, 670; relation of early diagnosis to prevention, 149; renal, 69, 708; report of the German commissioner on, 962; sanitary surveillance of, in New York City, 633; serum therapy of, 588; statistical laws of, 182; stricture of the colon, in intestinal, 671; surgery of urinary in women, 746; the home in relation to the problem of, 779; tonsillar, in children, 150; toxæmia associated with cervical, 588; transmission of bovine, by milk, 71; United States association for the study of, 542; value of climate in genitourinary, 108.
Tulane University, bequest to, 64.
Tumors, biology of, 711; blood-circulation in, 1018; essential similarity of innocent and malignant, 1017.
Tunica vaginalis, free growths in the, 75.
Turkey, medicine in, 145.
Turpentine, a case of poisoning by, 1043.
Typhoid bacilli, agglutination of, by the serum of jaundice patients, 589; cultures, enriching method for, 31.
Typhoid fever, absence of Widal reaction in, 590; and dysentery combined, 381; arterial complication in, 591; associated with scarlet fever, 270; bacilli in the urine during convalescence, 589; bactericidal action of the blood serum in, 511; bacteriological researches in, 789; blood cultures in the diagnosis of, 457; castor oil in, 28; cerebrospinal symptoms in, 477; channels of infection of, 417; condition preceding, 656; desquamation of the skin in, 271; diagnosis of, 836; diagnosis of, in its earliest stages, 271; differential diagnosis of, 580; distribution of the ulcers in, 791; early blood changes in, 1045; ergot in, 668; gangrene of the skin following, 1058; immunization against, 312; in children, 107; infection of, through oysters and milk, 900; influence of, on the nervous system, 549; in Indianapolis, 965; in Leadville, 617; in Philadelphia, 890, 891; in Pittsburg, 99, 303; intestinal perforation in, 156, 680; laryngeal complications in, 28, 470; late effects of, on the heart and vessels, 537; leucocyte counts in, 495; lymph glands in, 749; malaria coincident with, 1044; management of epidemics of, 67; nervous complications of, 630; perforation in, 980; perforations of the appendix in, 667; prevention of, 97, 107, 931; prognosis of, 920; repeated chills in, 834; rupture of the mesenteric glands during, simulating perforation, 1023; serum diagnosis of, by Ficker's method, 1018; serum treatment of, 81; State laws for the prevention of, 377; sudden death in, 788; surgical features of perforation in, 354; thoughts suggested by Health Board statistics of, 905, 938; treatment of, 257, 837; treatment of perforations in, 587; value of a fecal fistula in perforation in, 920; venous thrombosis in, 792.
Typhoid spine, 40, 655.

U

Ulcer of the stomach, excision of the ulcer-bearing area in, 1022; tetanic attacks in, 749; rubber tissue and boracic acid in the treatment of varicose, 915.
Ulnar nerve, recurrent dislocation of, cured by operation, 230.
Ultramicroscopic bodies, means of identifying, 469.
Uncinariasis, 108.
Underfeeding, a consideration of, 811, 835.
University Medical College, controversy of, with the former faculty, 619.
University of Chicago, medical plans of the, 141.
University of Pennsylvania, faculty reorganization at the, 891; new medical laboratories of the, 1010.
Uræmia, hæmolytic power of the blood in, 469; pathogenesis of, 1060; reflexes in, 227.
Ureter, calculus in the, 309; rectal segment of the, 570; use of the cystoscope in catheterization of the, 437;
Ureteral catheterism in the diagnosis of renal disease, 668; surgery, progress of, 72.
Urethra, a nail in the deep, 1041; anterior and posterior divisions of the, 229; reflex cutaneous eruptions in disorders of the, 27; stricture of the female, 587.
Uric acid, present status of the question of, 310; relation of, to the clinical manifestations of gout and lithæmia, 687, 712.
Urie, John F., the naval medical service, 847.
Urinal, a new female, 38.
Urine, albuminous bodies of normal and nephritic, 840; cryoscopy of the, 31; detection of reducing agents in the, 745; determination of tubercle bacilli in the, 150; indigo red in the freshly voided, 229; recovery after protracted suppression of, 658; relief of incontinence of, in women, 148; the Kollmann five-glass test, 531; treatment of incontinence of, by lumbar puncture, 1058; vesical retention of, 1055; volumetric determination of uric acid and the purin bodies in the, 712.
Uterus, accidental perforations of the, 116; bicornis, pregnancy in, 1016. correction of retrodiplacements of the, 119; curettage of the, 508; dangers of injection into the cavity of the, 788; electrothermic clamps in the treatment of cancer of the, 981; exohysteropexy for displacement of the, 747; fibroids of the, 193, 514; hysterectomy for cancer of the, with pregnancy, 588; malignant degeneration of the cervix after hysterectomy for fibroma, 188; myomectomy of the gravid, 270; new instrument for Gilliam's suspension of the, 944; new method of suspension of the, 720; treatment of complete prolapse of the, 988; vaginal operation for cancer of the, 400.

V

Vacation for the doctor, 1054.
Vaccination, imitation of the scar of, 199; perils of neglected, 63; problem of, in the Philippines, 967.
Vaccine bodies, comparative morphology of, 677; bodies, demonstration of, 679; virus, contaminated, 457; virus, preparation of, 415; virus, tetanus bacilli in, 200; virus, tetanus germs in, 680;
Vagina, diphtheria of the, 427; formation of a, in congenital atresia, 77; removal of a pin from the, 549; syphilitic changes in the, 788.
Vaginal cæsarean section, 376, 411, 551, 1044; operations, technique of, 72.
Van Fleet, Frank, a new bill to regu-

late the practice of osteopathy, 546.
Veins, regeneration of ligated, 799; sclerosis and ossification of, 709.
Venous congestion, Bier's, 1044.
Vera Cruz, sanitation of, 342.
Vertigo, aural, removal of the semicircular canals in a case of unilateral, 1017; labyrinthine, associated with ocular symptoms, 468.
Vienna, letter from, 928.
Volar sound, 469.
Vomiting, inhalation of oxygen in, 55. of pregnancy cured by electricity, 90.
Vulva, differential diagnosis of syphilis of the, from cancer, 73.
Vulvovaginitis, gonorrhœal in children, 748.

W

Wakefield, Homer, commentaries upon lues and leprosy as subcatabolic diseases, 9.
Walker, Emma E., professional byways open to medical women, 864.
Walrus fin, a case of, 76.
Walsh, James J., antistreptococcus serum in pernicious anæmia, 333.
Ware, Martin W., an automatic hemorrhoid clamp, 1065.
Warts and moles, danger of malignant degeneration of, 977.
Washington University, exhibit of the medical department of the, 1011
Water, Bacillus coli communis as an indication of sewage contamination of, 140; supplies, rural, 535; supply, typhoid fever transmitted by, 900; the Agricultural Department's method for the purification of, 615, 621; toxicogenic germ in, 628.
Watkins, V. E., the simultaneous occurrence of typhoid and malarial fevers—the same patient, 1044.
Weir, Robert F., presentation of portrait of, to the New York Academy of Medicine, 593; tribute to, 383.
Weiss, L. D., x-ray diagnosis of an interesting case, 919.
Weltmerism, a set-back for, 23.
Whipping in the public schools, 378.
Whiskey, adulteration of, 221; pure, 346.
White, A. Campbell, liquefied air, 93.
Whitman, Royal, a new treatment for fracture of the neck of the femur, 441.
Whooping-cough, abdominal belt for, 983; fatality of, 143.
Wiener, Alfred, modern treatment of dacryocystitis, 527.
Wiener, Richard, Jr., operation for congenital saddle-nose by introduction of a celluloid plate, 608.
Wilbur, Marple B., foreign bodies in the eye and their removal with the electromagnet, 1029.
William Pepper Laboratory of Clinical Medicine, 977.
Wines, use of table, 388.
Wintergreen, fatal poisoning with oil of, 591.
Winters, Joseph E., etiology of rheumatism; its obscurity, insidiousness, prevention, and management in childhood, 41.
Women, American, 1008; medical, professional byways open to, 864; unclassified troubles of, 766.
Wood, H. Walton, a case of hyperpyrexia with recovery, 1041.
Worms, podophyllin for intestinal, 428.
Wounds, general sepsis from, 506; gunshot, 318; influence of old age, diabetes, arteriosclerosis, and gout on the healing of, 970; modern treatment of, 187; treatment of granulating, 174.
Wry-neck, treatment of, 271.

Y

Yeast, therapeutic value of, 140.
Yellow fever, campaign against, in Mexico, 738; conveyance of, by Stegomyia fasciata, 761; etiology of, 309.

Z

Zygomatic arch, fracture of the, 754

LIST OF CONTRIBUTORS TO VOL. LXV.

ADLER, I., New York.
ALTSHUL, H., New York.
ANDERSON, JOHN F., U. S. Public Health and Marine Hospital Service.

Cystogen Aperient
GRANULAR EFFERVESCENT SALT OF CYSTOGEN

INDICATED WHEREVER ELIMINATION IS BELOW PAR

Prophylactic and resolvent in uric acid conditions. Cystogen Aperient dissolves uric acid and phosphatic sediments and exercises a beneficial eliminative effect on the whole organism—tones the stomach and bowels and flushes the urinary tract with a dilute solution of Formaldehyde. Of special value in Rheumatism, Gout, Urinary Deposits, Calculus, Cystitis and Gonorrhoea.

An Anti-Uric Acid Aperient and Urinary Antiseptic, Diuretic, Eliminative and Prophylactic

Dose:—A heaping teaspoonful three or four times daily.
Samples and literature will be furnished on request of physicians.

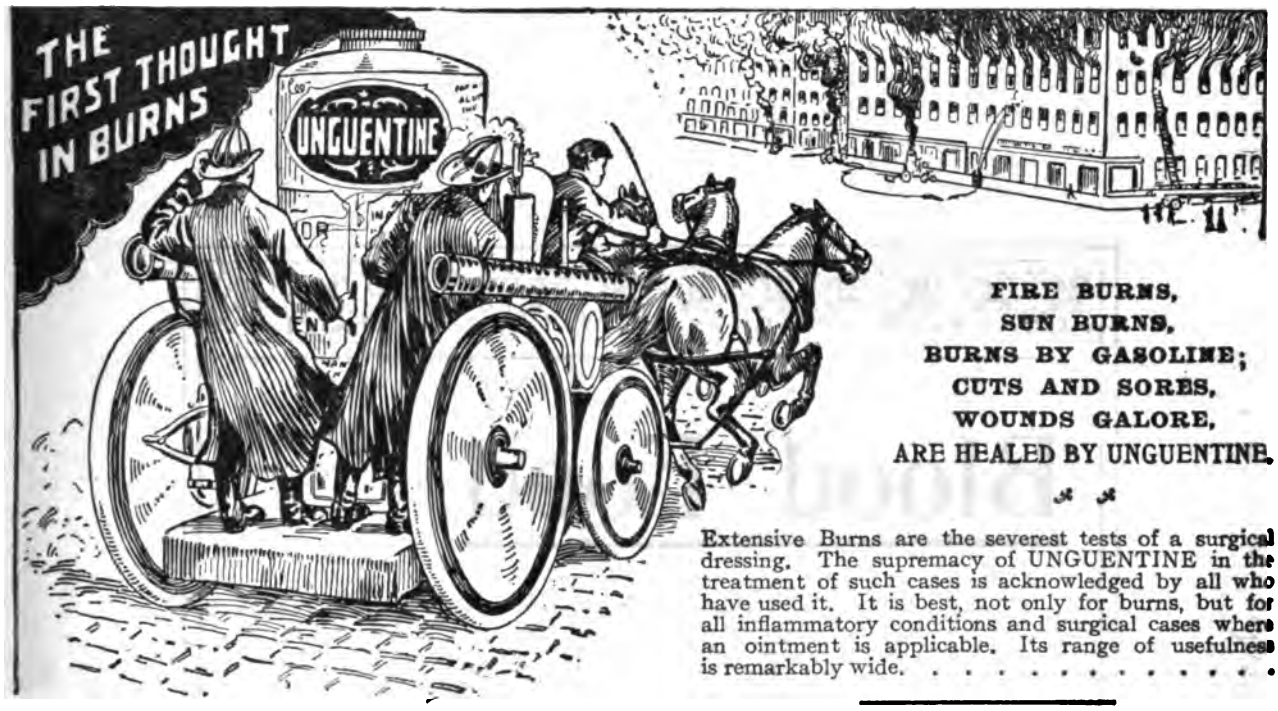
URINARY ANTISEPTIC



FIRE BURNS,
SUN BURNS,
BURNS BY GASOLINE;
CUTS AND SORES,
WOUNDS GALORE,
ARE HEALED BY UNGUENTINE.

Extensive Burns are the severest tests of a surgical dressing. The supremacy of UNGUENTINE in the treatment of such cases is acknowledged by all who have used it. It is best, not only for burns, but for all inflammatory conditions and surgical cases where an ointment is applicable. Its range of usefulness is remarkably wide. . . . . .

Gastric and Enteric Diseases

Diarrhoea, Dysentery and Cholera Infantum

Where a non-irritating, easily assimilated, rapid blood-making nutrient is needed, which can readily be taken by the youngest child, when all other forms of food fail, **Valentine's Meat-Juice** is recommended by eminent practitioners.

H. H. Powell, M. D., *Professor of Obstetrics and Diseases of Children, Western Reserve University, Ohio:*—"If I was asked in what class of cases Valentine's Meat-Juice has proved of most value in my hands, I should say Cholera Infantum and the Dysenteries of Children. Nutritious and stimulating, surprisingly so over any other product, it is so agreeable to the taste as not to be refused by any infant, however sick, and is so entirely assimilated as to leave nothing to irritate the lower bowels."

Professor Ad. Baginsky, *Professor Director of Emperor and Empress Frederick Hospital for Children, Berlin, Germany:*—"I have used Valentine's Meat-Juice with advantage in the peculiar Gastric and Enteric forms of diseases of Children, especially such cases which require rich, strengthening nourishment, without, however, giving the least inconvenience to the intestinal tract (stomach and intestines)."

Physicians are invited to send for brochures containing clinical reports from hospitals and general practitioners in all parts of the world.

For sale by American and European Druggists and Chemists.

VALENTINE'S MEAT-JUICE COMPANY, Richmond, Virginia, U. S. A.

Blood Food

To feed the body and starve the blood is like pouring water through a sieve. If the blood is thin and weak, the digestive power of the body is weak. Why feed it food that it cannot take care of?

Feed the blood with

Pepto-Mangan ("Gude")

and the whole body is strengthened and reorganized, and the digestive tract will promptly perform its normal function. The already weakened stomach is not compelled to do extra work; PEPTO-MANGAN ("GUDE") is immediately taken up by the blood and does not produce any gastric disturbance.

To assure proper filling of prescriptions, order Pepto-Mangan ("Gude") in original bottles containing ℥ xi. IT'S NEVER SOLD IN BULK.

PEPTO-MANGAN ("GUDE") is ready for quick absorption and rapid infusion into the circulating fluid and is consequently of marked and certain value in all forms of

Anæmia, Chlorosis,
Bright's Disease,
Rachitis, Neurasthenia, etc.

Samples and literature upon application.

M. J. BREITENBACH COMPANY,

LABORATORY, LEIPZIG, GERMANY.

53 Warren Street, NEW YORK.

BOVININE in ANÆMIA

BOVININE overcomes *Anæmia* logically, rationally and radically, for several substantial reasons:

1. Because it supplies the starving organism with the requisites for immediate reparation.

2. Because it needs no preparation or transformation at the hands of the vital machinery before it can be assimilated and converted into living force. Scores of theoretically excellent foods lack this vital condition, and are therefore appealed to in vain.

3. Because the condition called *Anæmia* results from a form of malnutrition which is not caused by lack of any nutritive element, but by the absolute inertia of the digestive function.

BOVININE comes to the rescue by supplying a vitalized and perfectly compounded pabulum that calls for no chemico-vital effort or expenditure whatever.

Have we made the contrast between **BOVININE** and all the rest of the prepared foods distinct enough?

If not, please apply the crucial test—clinical use—at our expense, and convince yourself that our claims are neither extravagant nor exaggerated, but are strictly based on science.

The Bovinine Company

75 West Houston Street, NEW YORK

VERONAL. Diethylmalonylurea. Reported to be the safest of all hypnotics, old or new. Average dose: 10 grains, best given dissolved in some hot liquid. Induces a practically normal sleep. Does not affect the heart, circulation, or the kidneys. Try it in your next case of insomnia.

STYPTICIN. A thoroughly well established uterine hemostatic. Occupies a field of its own, being devoid of oxytocic action. In powder and in sugar-coated and hypodermic tablets.

IODIPIN. An organic liquid combination of iodine. Is now a standard preparation, possessing all the therapeutic value of the iodides without their disadvantages. The only iodine compound eligible for hypodermic administration. Specific action in lues, scrofula, glandular enlargements, etc. 10 and 25 per cent. strengths. Well worthy a trial in your practice.

BROMIPIN. An organic bromine compound, analogous to iodipin. Renders excellent service in epilepsy.

ICHTHYOL. The sovereign antiphlogistic. No single remedy or combination of remedies is capable of doing so much in all forms of inflammation as is ICHTHYOL. A specific in erysipelas. An indispensable remedy in gynecologic practice. Numerous imitations of ichthyol have appeared and are appearing from time to time. The profession is earnestly cautioned against the use of those imitations and so-called substitutes for ICHTHYOL, as besides being worthless many of them are distinctly injurious and irritating. Always specify Ichthyol Merck.

DIONIN. Ethyl-morphine hydrochlorate. Dose ¼ to 1 grain. Admittedly the least toxic of all morphine derivatives. An excellent cough sedative; as a morphine substitute in the treatment of morphinism; and as a lymphagogue in ocular therapeutics.

TANNALBIN. Tannin albuminate, exsiccated. Intestinal astringents should not be soluble in the stomach, and should reach the intestines undecomposed. If they are soluble they interfere with gastric digestion, and their effect for good on the intestines is almost nil. Tannalbin is insoluble in the stomach and exerts its action throughout the intestinal canal.

THIOCOL ROCHE. Potassium guaiacol sulphonate. A water-soluble, absolutely non-irritating, readily assimilable form of guaiacol. Entirely devoid of the odor and taste of guaiacol or creosote. Its great value in tuberculosis, in the various forms of bronchitis, etc., testified to by the highest authorities. Supplied in three forms: powder, 5-grain tablets, and syrup thiocol Roche (6 grains to the fl. dram).

HEMOGALLOL. A true organic form of iron. Easily and rapidly absorbed. Does not irritate the most sensitive stomach and never produces constipation. Dose: 4 to 8 grains. On the market in powder and 4-grain tablets.

FORMIN. Hexamethylene-tetramine Merck. Presents this ideal urinary antiseptic in its highest obtainable purity. In powder form, or preferably prescribed in Merck's 5 and 7½-grn. tablets.

Clinical Reports on Application. **Merck & Co.** New York.

IN THE TREATMENT OF

ANÆMIA, NEURASTHENIA, BRONCHITIS, INFLUENZA, PULMONARY TUBERCULOSIS, AND WASTING DISEASES OF CHILDHOOD, AND DURING CONVALESCENCE FROM EXHAUSTING DISEASES,

THE PHYSICIAN OF MANY YEARS' EXPERIENCE

KNOWS THAT, TO OBTAIN IMMEDIATE RESULTS, THERE IS NO REMEDY THAT POSSESSES THE POWER TO ALTER DISORDERED FUNCTIONS, LIKE

"Fellows' Syrup of Hypophosphites"

MANY A TEXT-BOOK ON RESPIRATORY DISEASES SPECIFICALLY MENTIONS THIS PREPARATION AS BEING OF STERLING WORTH.

TRY IT, AND PROVE THESE FACTS.

SPECIAL NOTE.—Fellows' Syrup is never sold in bulk, but is dispensed in bottles containing 16 oz.

MEDICAL LETTERS MAY BE ADDRESSED TO

MR. FELLOWS, 26 CHRISTOPHER STREET, NEW YORK.

Lac-Bismo

A preparation of chemically pure Bismuth Salts for internal or external administration. It presents Bismuth in the most perfect form possible—a minutely sub-divided precipitate held in suspension in water, and is free from all the objections of ordinary Bismuth Salts

LAC-BISMO

Is indicated wherever the Salts of Bismuth are indicated. Wherever good results are derived from the use of the Bismuth Salts LAC-BISMO is capable of giving better results. You are acquainted with the virtues of the Bismuth Salts, why not become acquainted with the virtues of LAC-BISMO?

LAC-BISMO

combines with Alkalies, Anodynes, Astringents, etc., but not with Acids.

INTERNALLY

A sedative, tonic and mild astringent; useful in stomach and intestinal disorders, Subacute Gastritis, Gastralgia, Pyrosis and kindred diseases.

LAC-BISMO has proved of great value in irritation of the intestinal and urethral mucous membrane—Diarrhœa, Intestinal Dyspepsia, Dysentery, etc.

A trial in combination with Tinct. Catechu, Tinct. Kino, Tinct. Rhubarb, etc., for the above-mentioned disorders will give most gratifying results.

For CHOLERA INFANTUM, LAC-BISMO undiluted is a safe, reliable and efficient remedy.

EXTERNALLY

LAC-BISMO is considered a specific for ulcerated surfaces, chronic inflammation of mucous membranes, suppurating burns, etc.

Soothing in effect; prompt and certain in action.

Each fluid drachm represents or contains 5 grains of Medicinal Bismuth Salts

We solicit your correspondence. Samples, price list, pamphlets, and other data cheerfully furnished on application

535-537 Tchoupitoulas Street, NEW ORLEANS, LA.

GONOSAN

Best of the Anti-Gonorrhoics

A compound effectively uniting the therapeutic virtues of Kava-Kava and Santal-Wood Oil; containing the active principle (anæsthetic and diuretic) of the former, dissolved in pure East India Santal-Wood Oil.

Relieves the Pain; Prevents Complications; Shortens Duration of the Attack; Decreases Secretion; Inducing, in Cystitis, Rapid Clarification of the Urine, and Relieving Difficult Urination.

Supplied in 5-min. Gelatine Capsules; 50 in a box.

DOSE: *TWO CAPSULES FOUR OR FIVE TIMES A DAY, ONE HOUR AFTER MEALS . .*

J. D. RIEDEL, Manufacturer, Berlin, Germany.

LITERATURE AND SAMPLE BOX CONTAINING 30 CAPSULES SENT TO PHYSICIANS ON REQUEST.

LEHN & FINK, Sole Agents, NEW YORK

Prophylactic and Curative Externally and Internally

Unusual success in the treatment of Catarrhal diseases of the Vaginal mucous membrane by a few local physicians, ten years ago, has led to the general employment of

TYREE'S ANTISEPTIC POWDER

Aggressive Physicians have found it an entirely safe and economic Antiseptic, Disinfectant, Prophylactic and Curative, and now use it exclusively upon all the mucous membranes, externally and internally for local effect. We want every physician to give this powder a trial.

Sample and a beautifully illustrated little booklet representing the rare obstetrical and gynecological specimens of the Army Medical Museum at Washington, mailed free of charge to physicians.

J. S. TYREE, Chemist, Washington, D. C.

The Standard Antiseptic Aperient

Every Medical Practitioner recognizes the necessity of having at hand a thoroughly reliable aperient which must be palatable and at the same time devoid of all irritating qualities. This exactly describes Kutnow's Improved Effervescent Powder, which is recommended by the Medical Profession and indorsed by the Medical Press all over the World. In Kutnow's Powder are incorporated the rare medicinal and curative properties of the European Spas. It is sure, safe, and may be prescribed for the most delicate constitutions with perfect success.

MEDICAL

Sir Morell Mackenzie, M.D.

"I have tried Kutnow's Powder and find it answers particularly well."

Dr. J. Bond Sullivan, M. R. C. S.

Knock, Ennis, Co. Clare, Ireland.

"Having personally derived much benefit from Kutnow's Powder I have recommended it to several lady patients, who approve of it greatly."

Dr. Scott Nichol.

420 St. Antoine St., Montreal.

"The action of Kutnow's Powder on the stomach and bowels could not be improved."

Dr. Atkinson.

89 Albion Street, Leeds.

"I am employing Kutnow's Powder constantly with complete satisfaction."

APPROVAL

Professor Lawson Tait, M.D.

"Lawson Tait highly recommends Kutnow's Powder."

Dr. Josef Roth, Buda-Pesth.

I found Kutnow's Powder of great assistance in the mechanical treatment of torpid intestines. It also rendered essential aid in various affections of the heart, especially in cases of fatty degeneration."

Dr. Max Porges, Marienbad.

"I have prescribed Kutnow's Powder from time to time and have always found it reliable and thoroughly efficient. It is gentle in action and causes no irritation to the mucous membrane nor any injurious after-effects. I have obtained most excellent results from its use in cases of Dyspepsia, Hyperæmia of the Liver, Intestinal Catarrh, and Chronic Constipation."

SAMPLES FREE TO PHYSICIANS

Dr. D. McNeil.

Holme, Kirkwall, Scotland.

"I always use and prescribe Kutnow's Powder, and could not get on without it."

PRACTICAL GYNECOLOGY

PRACTICAL GYNECOLOGY

A TEXT BOOK

By EDWARD E. MONTGOMERY, M.D.

Professor of Gynecology in Jefferson Medical College, Philadelphia; Gynecologist to the Jefferson and St. Joseph's Hospitals, etc.

A PRESS REVIEW—ONE OF MANY SIMILARLY FAVORABLE:

"This second edition of this practical work is marked by all the excellencies of the first, and, without a great increase in size, much new material has been introduced. Many new illustrations of gross and microscopical sections have been added, and new operative measures have been pictorially presented.

The work is essentially practical, well-balanced, and sane, a fit companion for the student and practitioner."—*New York Medical Journal.*

Second Edition, Revised and Enlarged. With 539 Illustrations, many of which are from original sources. Octavo; 900 pages. Cloth, $5.00; Leather, $6.00, *net.*

Complete Description Sent Free Upon Request.

P. BLAKISTON'S SON & CO.,
Publishers,
1012 WALNUT STREET, PHILADELPHIA.

VAPORIZED CRESOLENE

is a positive safeguard against the injurious sequelae of

MEASLES

and alleviates the inflammation of the bronchial tubes.

The use of this powerful antiseptic does not conflict with other medication.

"ROENTGEN" COILS

Write for **Catalogue 482,** "*Roentgen Induction Coils and Other X-ray Apparatus*," of great interest to X-ray workers.

Complete outfits for fluoroscopic, radiographic and therapeutic use; operating from direct or alternating circuits. *X-ray tubes for all purposes.*

Our **working exhibit** (with photographic dark room) can be inspected any week day—except Saturday—between 2 and 5 P.M.; at other times by appointment. We show just what the apparatus *will do.*

J. L. Wicks, M. D., Prest., Evanston, Wyo.

Details are wanting in several instances, either because dates are not yet fixed, or because no response has been made to our request for information.

CONSUMPTION

One of the greatest dangers of consumption is its insidious onset. The patient remains unsuspicious of the disease. Bronchitis!—Maybe—but alas, too late, is he conscious of the consuming disease.

Do not turn away your eyes from this. Your interests cannot afford it because we will be of assistance to you, if you have any tubercular patients. Perhaps the lungs are not affected, yet this applies to any tissue of the body.

McArthur's Syrup of Hypophosphites

Has stood the test during many years for unequaled efficacy in the treatment of Tuberculosis. It has proved itself, time and time again, to be positively beneficial in this condition in the hands of prominent observers, clinicians, and what is more, average practicing physicians, hundreds of whom have written us their admiring enconiums in its behalf, and it is the enthusiastic conviction of many that its effect is truly specific.

Space limits our placing before you in detail the merits of our preparation, but we wish to send you our Pamphlet on Tuberculosis, our Chart on Diseases of the Lungs and Throat, a 1904 Calendar, a Sample Bottle (one-quarter of regular size), free to any physician applying, and to correspond with you in accordance with medical ethics.

THE McARTHUR HYPOPHOSPHITE CO.

ANSONIA, CONN.

Style No. 55D Table — Sims Position

The IMPORTANCE of EQUIPMENT

is no longer disputed. Every physician realizes that improved appliances enable him to cure for his patients more quickly, more accurately and with less effort.

He appreciates, also, the psychic value of artistic design and finish, and finds in

The Allison Tables and Cabinets

perfect adaptation to modern methods of practice.

Catalog A, sent free, tells the whole story. Write for information on our Static Machines and Medical Vibrators (Bihlmaier.)

Pulvola Chemical Co., 178 Fulton St., N.Y.

CHARACTER OF COMMENDATIONS

DIOVIBURNIA GERMILETUM NEUROSINE

Dysmenorrhea and Excessive Leucorrhea.

I very cheerfully give my testimony to Dioviburnia, prepared by an able pharmacist of this city. I have employed this medicine in cases of dysmenorrhea, suppression of catamenia, and in excessive leucorrhea, with satisfactory results. I recommend its trial, believing it will give entire satisfaction.

Dean and Late Prof. of the Principles and Practice of Medicine, St. Louis Medical College.

Geo. B. Johnson

Unexcelled in Dysmenorrhea.

I have used Dioviburnia sufficiently frequent to satisfy myself of its merits. It is unexcelled in painful dysmenorrhea, possessing antispasmodic properties exerted especially on the uterus.

Professor of Surgery, Missouri Medical College, and Post-Graduate School.

Wm. H. Tuholske

A Well Known Pharmacist.

For a long while I have prescribed Dioviburnia, prepared by a well-known St. Louis pharmacist, in those painful functional disorders of the uterus and appendages occurring in cases that come under my care for renal and vesical diseases with results satisfactory.

John R. Byrnes

Late Professor of Genito-Urinary Organs, St. Louis Medical College.

For years I have prescribed Dioviburnia in almost every form of dysmenorrhœa—especially the congestive form. I am so pleased with Dioviburnia that I now prescribe it almost daily.

Late Physician-in Chief and Gynecologist to St. John's Hospital, St. Louis.

J. L. Papin M. D.

The Best Uterine Tonic and Antispasmodic.

Dioviburnia is the best uterine tonic and antispasmodic, relieving the pains of dysmenorrhœa and regulator of the uterine functions. I freely give this recommendation of Dioviburnia, as it is neither a patented nor a secret medicine.

L. Ch. Boisliniere M.D.

Late Professor of Obstetrics, St. Louis Medical College.

Hemophilia. Restful Sleep.

Paragraph from original paper, "Two Cases of Hemophilia," by Prof. A. C. Bernays: "A terrific hemorrhage called me to a patient's bed about forty-eight hours after the operation, and from that time on for eight days, in spite of all I could do, the hemorrhage continued. He became almost bloodless. He also suffered from loss of sleep, caused by our incessant attempts at stopping the hemorrhage. I ordered for him Neurosine, after three doses of a teaspoonful, given one hour apart, resulted in a deep sleep, lasting eleven hours, at expiration the hemorrhage had ceased.

Formerly Professor of Surgery, Marion-Sims Medical College.

A. C. Bernays

Certainly the Best Neuralgic Medicine.

"I take this opportunity to express my gratification as to the happy results obtained from the use of Neurosine. It is certainly the best neuralgic medicine I have used. I have tried it in two cases of trifacial neuralgia after having tried some of our most powerful remedies, such as belladonna, opiates, gelsemium, arsenic, etc.; none have acted so well as Neurosine."

Late editor of the *Memphis Medical Monthly*, Memphis, Tenn.

J. A. Watts

Calmative Unexcelled in Restlessness of Fevers.

"I have found entire satisfaction from the use of Neurosine in my practice. I consider it the best sedative and calmative. Unexcelled in restlessness of fevers."

Late Prof. and Dean Memphis Hospital College of Medicine.

A. L. Gihon

Perfect Nerve Calmative and Natural Sleep Producer.

"I prescribe Neurosine in the class of cases for which it is indicated with satisfactory results. It is unexcelled in sleeplessness of fevers. A perfect nerve calmative."

Editor of the *Virginia Medical Monthly*, Richmond, Va.

Landon B. Edwards

Neurosine and Dioviburnia contains no Opium, Chloral, Morphine or other deleterious drugs.

Germiletum

OPPOSED TO GERM LIFE

The "Bete-Noire" of the Physician.

"Eczema often proves the 'bete-noire' of the physician's life. The erythema, the papules, the vesicles or pustules, singular or in combination of all three lesions in their various forms or degrees, with more or less infiltration and intolerable itching, followed by desquamation, discharge or formation of crusts, coming in crops and with a persistence that seems unyielding, leads us to welcome an agent so admirable as 'Germiletum,' which relieves the itching and irritation instantly, and continuing the application of Germiletum this inveterate disease will be entirely eradicated."

W. H. Garnett St. Louis, Mo.

Chronic Eczema and Catarrh.

"I take great pleasure in saying that I have used Germiletum in several cases of chronic eczema and catarrh with great improvement.

Colorado Springs, Colo.

Rhinitis, Eczema and Catarrh.

"I have used Germiletum in many cases of Rhinitis with the most excellent results. There is no better remedial agent in eczema and catarrh."

Washington, D. C.

Ideal Remedy for Catarrh.

"Authorities—and our experience teaches that the most important step towards the amelioration of Chronic Nasal Catarrh is cleanliness. A generous use of alkaline antiseptic with spray, sufficiently stimulating to encourage the formation of new blood vessels and invigorate those that have remained, thus increasing nutrition and the formation of regenerative elements. Such remedial agent should be solvent to facilitate the removal of all offensive and excessive seretions with the accumulations. That which has proven in my hands the ideal solvent and stimulating alkaline antiseptic is Germiletum. By its persistent use twice or thrice daily, full strength or diluted where the mucous membrane is sensitive, will effecually cure the most advanced case of Chronic Nasal Catarrh. In chronic cases persistent treatment is necessary.

Formerly Physician of the City Hospital, St. Louis, Mo.

A. M. Latimer

Surgery, Eczema, Catarrh, Gynecology and Obstetrics.

"The value of Germiletum as a non-irritant germicide is accentuated by the fact that its use has been followed by such excellent results in surgery, gynecology, obstetrics, and especially in Eczema. It is particularly adapted to catarrhal conditions, not only of the skin, but of all the mucous membranes which are usually caused by micro-organisms. Nasal catarrh, which has long been an odium of medicine, may now be successfully combated by this alkaline antiseptic, Germiletum."

Professor of Dermytology in the Physicians and Surgeons, and Editor of *St. L. Medical and Surgical Journal*, St. Louis, Mo.

W. H. Ohmann-Dumesnil

Physicians unacquainted with Dioviburnia, Neurosine and Germiletum, full size bottles of each furnished free, they paying express charges.

Look bill file reminder, with formula and literature, mailed postpaid on application.

DIOS CHEMICAL CO., ST. LOUIS, MO.

SAVE THEM FROM THE QUACKS.

Patients suffering from obscure nervous manifestations should receive careful and considerate attention from their medical advisers.

Sufferers from nervous troubles, particularly Sexual Debility, are often neglected or treated with indifference when they seek medical advice, then they go to see a quack!

Viriline is a true aphrodisiac and Nerve Tonic, is a scientific combination, and will be found of great value in the treatment of Presenility, Senility, Impotence and General Debility.

The often mis-used word "Neurasthenia" is a convenient term for describing conditions amenable to Viriline. Write for full information in reference to Viriline to the sole manufacturers, Osborn-Colwell Co., 46 Cliff St., New York.

SAVE THEM FROM THE QUACKS.

Every physician wishes to establish a reputation for curing his patients promptly. For over twenty five years Tongaline has been recognized by the medical profession as the standard prescription for RHEUMATISM, NEURALGIA, GRIPPE, SCIATICA, LUMBAGO and GOUT. In every instance where Tongaline is used a physician secures certain results *from* certain doses *in a* certain time. All the salicylic acid in Tongaline is from the purest natural oil of wintergreen

WHEN YOU USE THE SALICYLATES PRESCRIBE Tongaline

SAMPLES AND LITERATURE ON APPLICATION MELLIER DRUG COMPANY, ST. LOUIS.

TISSUE BUILDING IN TUBERCULOSIS

BURNHAM'S CLAM BOUILLON.

The maximum amount of food energy in the minimum bulk, conferring the greatest good on the body with the least tax on the digestive organs, is required for the nutrition of tuberculosis patients. Physicians will find

BURNHAM'S CLAM BOUILLON

(Absolutely Free from Any Preservative)

a superior tissue building food for these cases. It is concentrated, very appetizing, and has a high nutritive value. It is acceptable and soothing to the gastric membrane when other foods cannot be tolerated, and the ease with which it is absorbed saves the patient's strength.

Has stood the test of Fifteen Years, with a constantly increasing demand from Physicians and the Public.

That it is absolutely the pure juice of the clam without any preservatives is demonstrated by the fact that it spoils with undue exposure to the atmosphere. **BURNHAM'S CLAM BOUILLON** is put up in glass bottles and sold in pints and half pints. This assures not only cleanliness and convenience in the serving, but perfect purity and freshness while using in the sick room. All the leading apothecaries and grocers sell it.

E. S. BURNHAM CO., MANUFACTURERS AND PACKERS, 53 to 61 Gansevoort Street, New York.

THE NEW

SOPORIFIC SEDATIVE ANODYNE

PAS-AVENA

POWERFUL, BUT ABSOLUTELY HARMLESS.

CONTAINS no Morphine or Opiates, Chloral, Bromides, Sulphonal or Paraldehyde. Introduced as a substitute for the many injurious narcotics and antispasmodics now in general use. Possesses a pronounced specific action as a nerve sedative and hypnotic. Insures nerve tranquillity and induces a calm neural equilibrium. Invaluable in Insomnia, Hysteria, Neurasthenia, Convulsions, Epilepsy, Tetanus, Chorea, Spasmodic Asthma, Neuralgia, Alcoholism, Morphine or Opium Habit, and all conditions resulting from Impaired Nerve Function.

A Single Trial Will Soon Convince You of its Analgesic and Sedative Qualities.

DOSE.—Teaspoonful, repeat half-hourly if necessary. Children in proportion to age. Where immediate action is required a dessertspoonful or tablespoonful may be administered at a single dose with safety.

Literature Free upon Application. A Full Size Bottle for Trial Purposes will be sent to Physicians who will pay express charges.

VIN MARIANI INTRODUCED NEARLY HALF A CENTURY AGO:

"The Preparation which made Coca known as a remedy!"

ONLY EXCLUSIVE COCA LABORATORIES IN THE WORLD

AT NEUILLY SUR-SEINE, PARIS, FRANCE, ESTABLISHED AND DIRECTED BY M. MARIANI.

Priority, Facilities, Processes of Manufacture and Personal Supervision

MAINTAIN MARIANI COCA PREPARATIONS INIMITABLE.

AVOID "COCA WINES" Extemporaneously made with **Cheap Wine and Cocaine.**
These Substitutes harm both Patient and Physician and betray confidence in the unique properties of Coca.

BECAUSE of false wines foisted on the public in imitation of VIN MARIANI and because of the evil against a valuable remedy, Physicians urged us to denounce these frauds through overwhelming facts.

This being in a measure accomplished, **OUR COCA PREPARATIONS** are advertised exclusively to the Medical Profession in the same conservative manner that has enlisted ethical support.

VIN MARIANI

Represents only TRUE COCA with a Sound Nutritious FRENCH WINE; Invariably Uniform and Reliable.

AN ADJUVANT TO ALL OTHER REMEDIES IN

CONVALESCENCE—WASTING DISEASES—NEURASTHENIA

And Allied Conditions from any cause.

THE COCA LEAF

A PERIODICAL EPITOME OF CURRENT MEDICINE ADVOCATING THE RATIONAL USES OF COCA;
MAILED FREE
TO PHYSICIANS ON REQUEST.

Inquiries from the Profession receive prompt consideration.

MARIANI & CO.,

52 West 15th St., New York.

LABORATORIES: NEUILLY SUR-SEINE, FRANCE.

PARIS, 41 Boulevard Haussmann; LONDON, 49 Haymarket; BERLIN, 56 Charlotten Strasse; MONTREAL, 97 St. James Street.

A Seattle Gynecologist

recently wrote for a sample of THIGENOL Roche. "It seems to me," he observed incidentally in his letter, "that in your ad in *American Medicine* you really say a strong word for ichthyol."

To this we replied:

"Very true; but in all the years that ichthyol has been employed, physicians have ardently wished for something as good as it which would be free from its disagreeable physical properties — abominable smell and staining qualities.

"Thigenol is the outgrowth of those wishes."

Thigenol contains 10 per cent soluble organic sulphur; ichthyol contains only 8 per cent. Thigenol is odorless on use, whether in solutions, suppositories, ointments, tampons, although it has an odor in the container. Ichthyol has a nauseous, clinging smell.

Thigenol is employed in skin diseases, gynecological affections, rheumatism, hemorrhoids, gonorrhea, and in catarrhs of the respiratory tract.

We'll be glad to send a liberal sample of Thigenol, together with our Monograph and Formulary. The sample may be sent to your office or to your druggist.

51-53 Maiden Lane — The Fenwick Agency — New York

SYRUPUS ROBORANS.

SYRUP HYPOPHOSPHITES COMP. WITH QUININE. STRYCHNINE AND MANGANESE.

1-128 grain Strychnine to teaspoonful.

The pharmaceutical skill displayed in making this favorite compound more stable and agreeable deserves the approbation of the profession.

SYRUPUS ROBORANS AS A TONIC DURING CONVALESCENSE HAS NO EQUAL.

As a nerve stimulant and restorative in wasting and debilitating diseases, as a constructive agent in Insomnia, Pneumonia, Tuberculosis, Bronchial Asthma, Marasmus, Strumous Diseases and General Debility, this compound has no superior. Owing to the solubility of the salts, addition can be made of Fowler's Solution, Syrup Iod. Iron, Iod. Potass., etc., giving the advantages of those remedies without interfering with the stability of the preparations. **SYRUPUS ROBORANS** is a perfect solution, and will keep in any climate.

Dr. W. O. Roberts says: "In cases convalescing from 'La Grippe,' Syrupus Roborans has no equal."

MESSRS. ARTHUR PETER & Co., Louisville, Ky.

Gentlemen: — The excellence of your preparations — **"SYRUPUS ROBORANS"** and **"PEPTIC ESSENCE COMP."**—cannot be questioned. I use both in my practice, and have always been pleased with the effect of each. Respectfully, J. M. MATHEWS, A.M., M.D.,

Prof. of Surg. and Diseases of Rectum, Hosp. Coll. of Med.; **ex-Pres. Am. Med. Ass'n,** and Miss. Valley Med. Ass'n; Pres. Ky. State Board of Health.

Please note that Essence and Elixir Pepsin contain only Pepsin, while in

PETER'S PEPTIC ESSENCE Comp.

we have all the digestive ferments. These are preserved in solution with C. P. Glycerine in a manner retaining their full therapeutic value, which is exerted in and beyond the stomach.

PETER'S PEPTIC ESSENCE COMP.

A POWERFUL DIGESTIVE FLUID IN PALATABLE FORM.

It is a Stomachic Tonic, and relieves Indigestion, Flatulency, and has the remarkable property of arresting vomiting during pregnancy. It is a remedy of great value in Gastralgia, Enteralgia, Cholera Infantum, and intestinal derangements, especially those of an inflammatory character. For nursing mothers and teething children it has no superior. Besides mere digestive properties, Pepsin and Pancreatine have powerful soothing and sedative effects, and are therefore indicated in all gastric and intestinal derangements, and especially in inflammatory conditions. It is perfectly miscible with any appropriate medium. In certain cases the addition of Tr. Nux Vomica gives much satisfaction. Please write for Peter's Peptic Essence Comp., and you will not be disappointed. These preparations are held strictly in the hands of the medical profession, never having been advertised as popular remedies, nor put up with wrappers and circulars expatiating on the use of the Hypophosphites or Digestives, thus educating the public in the use of these valuable compounds.

Samples Sent upon Application. Express Charges at Your Expense. For Sale by all Wholesale Druggists.

ARTHUR PETER & CO. Louisville, Ky.

ANTIPHLOGISTINE'S

THERAPEUTIC ACTION is based in theory upon the following fundamental principles, its prime object being to keep the blood circulating in the diseased part:

The blood, which normally circulates fully and freely through the vascular system, is the food supply of the millions of cells which make up the body structure. Inflammation means certain successional deviations or interferences with the circulation in some part or parts. In health, the functions of the vascular system are automatically controlled by the central nervous system. Three-fourths of the body composition is fluid—chemically speaking, water, and as a magnet has affinity for particles of steel, so Antiphlogistine has affinity for water. Antiphlogistine is an antiseptic, a non-conductor of heat and a vasomotor stimulant. The skin may be regarded as a permeable membrane, separating two fluids of different densities, the blood and Antiphlogistine. If Antiphlogistine is applied hot under such conditions something definite happens and that scientifically—an interchange of fluids, most marked towards Antiphlogistine; hence the deduction that Antiphlogistine acts through reflex action and dialysis, the latter scientifically including the physical processes of exosmosis and endosmosis.

DEEP-SEATED STRUCTURES.—If Antiphlogistine is applied warm and thick, the thicker the better, for pneumonia, pleurisy, bronchitis, peritonitis, or any affection involving deep-seated structures, it maintains a uniform degree of heat for twenty-four hours or more; it stimulates the cutaneous reflexes, causing a contraction of the deep-seated and coincidently a dilatation of the superficial blood vessels; at the same time it attracts or draws the blood to the surface—flushes the superficial capillaries—bleeds but saves the blood; thus the aggravating symptoms will be almost always immediately ameliorated; congestion and pain are relieved; the temperature declines; blood pressure on the overworked heart is reduced; the muscular and nervous systems are relaxed and refreshing sleep is invited.

SUPERFICIAL STRUCTURES.—It is no longer proper to treat with the old fashioned bacteria-breeding flaxseed poultice, boils, felons, sprains, chronic ulcers, inflamed glands, periostitis and other types of inflammation involving comparatively superficial tissues. Antiphlogistine is a soothing antiseptic well adapted to sensitive and abraded surfaces. It draws out or absorbs the liquid exudate from the swollen and sensitive tissues, the result being that the blood is permitted to circulate freely through the affected area and nourishment is conveyed to the injured cells. Through reflex action and endosmosis a stimulating, alterative, tonic and soothing influence is exerted upon the affected cells, lymphatics and other tissues.

GENERAL DIRECTIONS.—Always heat in can (never on a cloth) by placing it in hot water. Do not allow water to get into the medicine. When as hot as can be borne, take a suitable knife and apply as quickly as possible, spreading the Antiphlogistine on the skin over the affected part, at least an eighth of an inch thick and covering promptly with a liberal supply of absorbent cotton and a suitable bandage or compress. Needless exposure to the air or contact with water markedly reduces the remedial value of Antiphlogistine, hence make all applications quickly. Remove dressings as soon as they will peel off nicely—in twelve to twenty-four hours.

To insure economy and the best results always order a full package and specify the size required—Small, Medium, Large or Hospital Size.

Bismutose

Bismuth : : Albuminate

(21% Metallic Bismuth)

Bismutose.—Succedanum to Subnitrate Bismuth in diseases of the gastro-intestinal canal of children and adults.

Bismutose is absolutely non-toxic and non-irritant even in two-ounce doses, and free from the metallic taste of the subnitrate.

Bismutose is practically insoluble in the stomach, but active in the intestines.

Indications: *Astringent* in intestinal disorders of nurslings, summer diarrhœas of children, and in acute, subacute and chronic catarrhal intestinal inflammation of children and adults. *Protective* in ulcerative, irritative, and fermentative processes of the digestive tract, Ulcers, Nervous Dyspepsia, Typhoid, etc.

DOSE: Large doses should be given. Children, 15 to 30 grains every hour; adults, ½ drachm to 1½ drachms, in milk or gruel. . .

STAYS the HAND of the SURGEON

Every man of wide experience in general practice hesitates to use even the curette in the uterine tract, and often sighs for some system of

BLOODLESS SURGERY

that would avail him there.

In endometritis and cervicitis accompanied by leucorrhea, it is of prime importance to equalize the circulation of the pelvis, reduce engorgement, and destroy bacilli causing the inflammatory process.

When all other means have failed and thorough curetting seems essential, try

Micajah's Medicated Uterine Wafer

This wafer, self-retained close to the os uteri, slowly dissolves, penetrating the diseased membrane.

In 3 or 4 days exfoliation begins to take place, and entire casts of the cervix and os are sometimes found after the hot water douche (100°-110°).

An astringent germicide that annihilates gonococci, a soothing tonic and alterative grateful to the most delicate tissue, this wafer

PREVENTS COMPLICATIONS

Write for our concise, authoritative little book entitled "Hints on the Treatment of Diseases of Women," which will be sent prepaid with generous samples of the Wafers, by

ACUTE — CYSTITIS — CHRONIC

YIELDS TO TREATMENT WITH

URISEPTIN

GIVE your patient one tablespoonful in a teacup of hot water. You will find that his urine will contain Formaldehyd in thirty minutes; one or two teaspoonfuls every three or four hours will keep it that way. The urine is rendered antiseptic. Irritation and pain subside. Healing of irritated surfaces begins promptly. The increased flow of urine flushes the entire urinary tract.

FORMULA—A Lithium Compound of Formaldehyd dissolved in Aqueous Fluid Extract of Corn Silk and Couch Grass (24 grs. to fluid ounce).

DOSE—Tea to tablespoonful every three or four hours, preferably in hot water.

At your request we will send a full size $1.00) bottle, if you send 25 cts. to pay express.

THE MEDICATED GELOPLASMS

correspond to the medicated gelatin pastes or plasters first suggested by Sigmund, of Vienna, and afterwards much improved by Pick, and Unna and Beiersdorf. The Geloplasm is a special glycerin jelly, prepared from gelatin and glycerin, and with this various remedies are incorporated. It is solid at ordinary temperatures, but readily melts with heat, and is to be painted with a brush, while liquid, in a thin layer, over the affected surfaces. It dries in a few minutes and forms a flexible elastic covering, perfectly excluding the air, and not rubbing off or soiling the clothing.

They possess the following advantages:

1. Exclusion of air.
2. Complete protection of the part.
3. Perfect immobility, insuring a fixed adhesive dressing.
4. Gentle, uniform compression.
5. Direct and prolonged therapeutic action.

THE GELOPLASMS are put up in 2-oz. jars, each jar containing sufficient to cover 125 square inches of surface.

This scene never enacted in homes where "The Best" Nurser is used

BECAUSE Babies Don't Cry who use

"THE BEST" NURSER

At Druggists, with a "Clingfast" Nipple, 25c.
From us, postpaid, 35c. Safe delivery assured.
THE GOTHAM CO., 52 Warren Street, New York

"CLINGFAST" NIPPLE
Warranted Pure Gum.
Right Size, Right Shape.
Small hole, easily made larger.
Simple, easily turned to cleanse.
No Ribs to catch secretion.
Baby cannot pull it off.
Outlasts 3 ordinary nipples.
Same price as cheaply-made, adulterated nipples—5 cents each, or 50 cents dozen. At druggists' or from us, postpaid.
The Gotham Co., 52 Warren St., N. Y.

A FEW TESTIMONIALS.

N. Y. Infant Asylum.—We recommend "The Best" Nurser most warmly, especially for the facility with which it can be kept perfectly clean.

Western N. Y. Children's Home, Randolph, N. Y.—"The Best" has been a wonderful aid in the healthfulness of our babies. We have discarded all other bottles.

L. A. Turnbull, M.D., St. Louis, Mo.—I recommend "The Best" Nurser. It is certainly a "God send"—especially to babies with stomach troubles.

W. J. Lemon, M.D., Auxvasse, Mo.—My baby has no wind colic since using "The Best." No other bottle ought ever be used.

C. O. Allen, M. D., Haydenville, O.—"The Best" Nursers are the best I have ever seen. Enclosed $1.05 for three more.

G. H. Fulford, M. D., Sioux Falls, S. D.—You certainly have the best Nurser in the market. I recommend it to all my patrons, and the "Clingfast" lasts much longer than other nipples.

C. B. Doane, M. D., Jamaica, Vt.—"The Best" Nurser is all you claim for it.

Dr. Nat. W. Williams, Laws Hill, Miss.—Our baby is an advertisement in herself for "The Best" Nurser. She has not had colic since we began using it; and before, it was a nightly affair. No nipples suit us like the "Clingfast."

W. H. Peck, M. D., Wheaton, Ill.—"The Best" is a splendid invention; I advise my patients to use it.

Patton Griffiths, M. D., Towanda, Pa.—I recommend "The Best" Nurser and "Clingfast" Nipple to the medical profession, as results attending their use have been so satisfactory.

J. K. Fairly, M. D., Creston, S. C.—I am using the "The Best" Nurser and find it as represented.

E. L. Tiffany, M. D., Guilford Centre, N. Y.—Out of six kinds of nipples tried, I prefer the "Clingfast."

ROYAL

Baking Powder.

INDISPENSABLE FOR PURE AND WHOLESOME FOOD.

Royal Baking Powder is made from cream of tartar, a product of the grape, and the most healthful of all fruit aids.

Royal Baking Powder vesiculates the dough by mechanical means, without fermentation, and in no way affects or changes the constituents of the flour. There is no destruction of the gluten or sugar, but all those elements are preserved which are intended by nature, when combined in our bread, to make it literally "the staff of life."

Fresh bread, cake, biscuit, griddle-cakes, etc., raised with Royal Baking Powder may be eaten with impunity by persons of dyspeptic tendencies or the most sensitive stomachs.

Food for the sick requiring to be leavened is made perfectly wholesome and more nutritious by the Royal Baking Powder than by any other vesiculating agent.

ANTIPYRIN "KNORR'S."

"Unquestionably the most important of the Antipyretics, Analgesics, Hemostatics and Local Anesthetics yet offered by the synthetic chemist."

ORTHOFORM.

Local Anesthetic, Antiseptic and Styptic. Applied to wounds insures analgesia for hours and days.

ALBARGIN.

A Nonirritating substitute for silver nitrate, freely soluble in cold water. Used in Gonorrhœa, Eye, Ear, Nose and Throat affections.

BENZOSOL.

(Guaiacol Benzoate). Antitubercular, Antidiabetic, Intestinal Antifermentative and Antiseptic. Used whenever creasote or guaiacol are indicated.

ANESTHESIN "RITSERT."

Odorless, Nonpoisonous, Local Anesthetic. Used also internally in gastric disturbances, such as Hyperesthesia, Ulcer and Carcinoma.

SECOND REVISED EDITION.

A TEXT-BOOK OF BACTERIOLOGY.

By GEORGE M. STERNBERG, M.D. LL.D.,

SURGEON-GENERAL, U. S. ARMY,

Ex-President American Public Health Association; Honorary Member of the Epidemiological Society of London, of the Royal Academy of Medicine of Rome, of the Academy of Medicine of Rio Janeiro, of the Société Française d'Hygiene

One large octavo volume, of 720 pages, illustrated by numerous full-page photographic and colored plates, and by two hundred engravings in black and colors. Extra muslin, $5.00 *net*; brown sheep, $5.75 *net*. : : : :

THE author's MANUAL OF BACTERIOLOGY has been the standard authority on this subject, both in this country and abroad, ever since its publication in 1892. It was most favorably received, although its size, while making it most comprehensive and complete, necessarily interfered somewhat with its usefulness.

Realizing that many practitioners, and nearly all students of medicine, feel the need of a work on Bacteriology less exhaustive than Sternberg's MANUAL, yet complete in all that pertains to the practical side of the subject, the author has prepared the present text-book.

It avoids all that might be considered as experimental and purely scientific, and confines itself to a thorough and practical consideration of the subject.

Detailed descriptions of the non-pathogenic bacteria, as well as the extensive bibliography, and the matter printed in small type, in Sternberg's MANUAL, have been omitted from the present TEXT-BOOK OF BACTERIOLOGY, while everything has been revised to include all the later additions to our knowledge of the pathogenic bacteria.

The work is illustrated by 200 wood-engravings, printed in black and colors; by five full-page heliotype plates, and four beautifully executed full-page chromo-lithographic plates.

SECOND EDITION, REVISED AND ENLARGED.

The Principles and Practice of

HYDROTHERAPY.

A Guide to the Application of Water in Disease.

FOR STUDENTS AND PRACTITIONERS OF MEDICINE

By SIMON BARUCH, M.D.

Professor of Hydrotherapeutics in the New York Post-Graduate Medical School and Hospital, Visiting Physician to the J. Hood Wright Memorial (Formerly Manhattan General) Hospital; Consulting Physician to the Montefiore Home for Chronic Invalids; Member of the New York Academy of Medicine; Formerly Gynæcologist to the Northeastern Dispensary; Physician for Eye, Ear and Throat to the Northwestern Dispensary of New York City; Physician and Surgeon to the New York Juvenile Asylum, and Chief of the Medical Staff of the Montefiore Home for Chronic Invalids.

Differing from all other works on hydrotherapy, this book is written by a general practitioner for the guidance of his colleagues.

The pages represent the observations of the author, who has labored in every branch of medicine, and who has gathered these data from a private and hospital practice extending over a third of a century, and more recently from special institution practice extending over a period of years and furnishing the recorded details of over one hundred thousand hydriatic treatments.

It is not the purpose of the author to write a panegyric upon Hydrotherapy, but to discuss water as a remedial agent precisely as medicinal remedies are discussed in the textbooks on therapeutics.

The first part of the book deals with the physical properties of water and its mode of action in health; the laboratory experiments upon which the latter is based being freely discussed. The second part is devoted to the practice of hydrotherapy. The various methods of applying water in disease are minutely described and illustrated, the *rationale* of each procedure is discussed, and its special therapeutic indications are outlined.

Having mastered the technical details, the reader is introduced to the practical application of hydrotherapy in acute and chronic diseases.

The author views with satisfaction the rapid rise of hydrotherapy since the publication of the first edition. He has endeavored in the present volume to eliminate matter which was required in the first to fortify his plea for the more universal utilization of water in disease. The entire work has been revised and much new matter has been added. A chapter on reaction is devoted to the elucidation of the basic principles of hydrotherapy in consonance with advanced physiology and the most recent experimental findings.

A chapter on insanity has been added, based upon the recorded observations of practical alienists in charge of large asylums, and a chapter illustrating the value of this agent in these ordinarily unsatisfactory cases.

In every part of the work the author has endeavored to inculcate the *rationale* of each procedure, and detailed the methods in such manner that the family physician may utilize the latter at the patient's home in the chronic as well as in the acute cases, and thus spare his patients the discomfort and expense of removing to hydrotherapeutic institutions.

Octavo, 506 pages, profusely illustrated. Extra muslin, $4.00 net. Sent, postpaid, on receipt of the price.

THIRD EDITION, REVISED AND ENLARGED

MANUAL OF THE DISEASES OF THE EYE

FOR STUDENTS AND GENERAL PRACTITIONERS

By CHARLES H. MAY, M.D.,

Chief of Clinic and Instructor in Ophthalmology, College of Physicians and Surgeons, Medical Department, Columbia University, New York—1890-1903; Ophthalmic Surgeon to the French Hospital, New York; Consulting Ophthalmologist to the Red Cross Hospital, New York; Adjunct Ophthalmic Surgeon to Mt. Sinai Hospital, New York City; etc.

THIRD EDITION REVISED AND ENLARGED

There can be no doubt that May on the Eye is the most popular small textbook on its subject now in the market. The first edition appeared in August, 1900. The second edition appeared in September, 1901, was exhausted in three weeks, and reprinted twice within a year.

The third edition has been carefully revised, and additions have been made wherever necessitated by the progress of medical knowledge. A number of new illustrations, including three more full-page plates, have been added. The volume will be found to be thoroughly up to date, but the size of the book has not been appreciably increased, as there is no doubt that the original plan of presenting the subject in concise, yet complete form, has met with the approval of both teachers and students throughout the country.

The illustrations are all original. The colored plates, containing sixteen figures, are exquisite examples of color printing, and represent the most common changes in the fundus, practically supplying an ophthalmoscopic atlas. The illustrations in the text have been made as simple as possible, in the belief that such illustrations are more instructive than elaborate pictures. Their technical execution is of the best.

One volume, 12mo, 424 pages profusely illustrated with 275 original figures, including 16 plates in black and colors. Extra muslin, $2.00 *net*.

WILLIAM WOOD & COMPANY, Publishers, - 51, Fifth Avenue, New York

THREATENED ABORTION

In these cases Hayden's Viburnum Compound exerts a sedative effect upon the nervous system, arrests uterine contraction and hemorrhage and prevents miscarriage. It has proven of special service in habitual abortion.

THE RIGID OS

This condition, which prolongs labor and so rapidly exhausts the patient and endangers the life of the fetus, is of common occurrence. H.V.C. acts most promptly and effectively and is not a narcotic. No less an authority than H. MARION SIMS, M.D., said: "I have prescribed Hayden's Viburnum Compound in cases of labor with Rigid Os with good success." A more convincing argument could not be presented.

POSITIVE RESULTS IN

Obstetrical Practice

WHEN YOU PRESCRIBE

H. V. C.

(Hayden's) (Viburnum) (Compound)

AFTER-PAINS

The value of H.V.C. after the third stage of labor cannot be over-estimated. Its antispasmodic and analgesic action modifies and relieves the distressing after-pains and quiets the nervous condition of the patient. By promoting the tonicity of the pelvic arterial system it prevents flooding, and thus eliminates this dangerous element in obstetrical practice.

A WARNING

The enviable reputation of the Viburnum Compound of Dr. Hayden, H.V.C., in obstetrics and in the treatment of diseases of women, has encouraged unscrupulous manufacturers to imitate this time-tried remedy. If you desire results, you must use the genuine only—beware of substitution.

NEW YORK PHARMACEUTICAL CO., Bedford Springs, Mass.

Food and the Principles of Dietetics.

By ROBERT HUTCHISON, M.D. Edin., M.R.C.P.;

Assistant Physician to the London Hospital and to the Hospital for Sick Children, Great Ormond Street.

The subject of Dietetics is one of the most important with which the physician must deal. While immense strides have been made in our knowledge, we can almost say, within the past few months, as a result of investigation concerning the chemical constituents, active principles and physiological action of various foods under different conditions, the records have not been made available in a collated and digested form, suitable for teaching purposes, until the appearance of the important work of Dr. Robert Hutchison, of London, "Food and the Principles of Dietetics." Acknowledging the great advances that have been made, as the result of the investigation and teaching of American specialists, Dr. Hutchison has made use of their work, as was, of course, necessary to bring the work up to date, in a thorough treatment of the subject.

PRESS NOTICES.

It is an excellent manual of Dietetics in a form that ought to render it one of the most popular text-books on its subject in our language. The author acknowledges his indebtedness to the American school of investigators in this department, more especially to Prof. Atwater and his colleagues, who have done as much as other recent investigators in any part of the world to advance the science of dietetics. The style of the work is taking, and it is certainly easy reading, which is an advantage.—*Journal of the American Medical Association.*

No matter how many works you have in your library on the engrossing subject of dietetics and nutrition, the subject which underlies all successful medical practice, don't hesitate for a moment to possess yourself of this volume. It is not so technically worded but that the intelligent layman will find it full of the practical facts of which he cannot know too much.—*Dietetic and Hygienic Gazette.*

The relative value of foods, food in health, the effect of occupation upon the amount of food required, detailed analyses of all the common foods, and of many not common, vegetarianism, beverages, including alcohol, the cooking of foods, digestion, infant feeding, and feeding in disease,—are all considered fully, clearly and practically. Completeness, so far as possible, is evident on every page.

It is a book so full of useful information that the reader cannot but peruse it with profit and yet so simple and delightful is the author's style that even the layman may read it with pleasure.—*Buffalo Medical Journal.*

A thick octavo of about 550 pages, fully illustrated, bound in muslin, price $3.00, *net.*

WILLIAM WOOD & COMPANY, - - 51, Fifth Avenue, New York.

SOLIFORM

(Liquor Detergens)

A thoroughly saturated antiseptic solution that is remarkably cleansing. **pleasant, non-irritant** and **healing.**

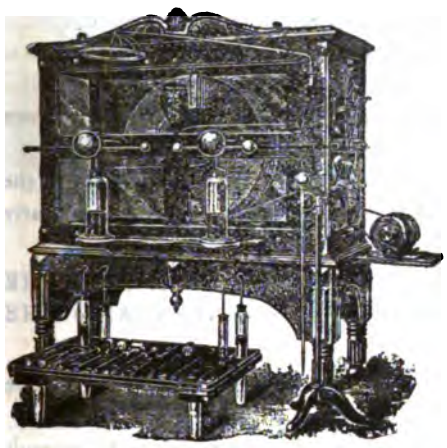
Is not sticky and **will not stain the linen.**

Absolutely safe for internal and external use.

Recommended in all Catarrhal Affections of the Mucous Membranes and as an adjunct in many Diseases of the Skin. **STRICTLY ETHICAL. TIME-TESTED.** SAMPLES AND FORMULA ON REQUEST.

MANUFACTURED ONLY BY

THE SOLIFORM CO., **447 West 125th Street, NEW YORK.**



We challenge the world to produce a Static Machine or an X-Ray Coil equal to those we manufacture.

The physician's fluoroscopic examinations and his efforts in radiography will pass for almost nothing unless he has a Static Machine or an X-Ray Coil so constructed as to generate currents of high voltage and maximum amperage. These essential properties are characteristic of our instruments. We are sole manufacturers of Dr. Piffard's High Frequency Current Apparatus, Ultra-Violet Ray and Hand Arc Lamps. For description of new devices send to 217 East Twenty-third Street, New York, for our Catalogue

ANTIKAMNIA PREPARATIONS

ANTIKAMNIA & SALOL TABLETS

Hare says "Salol renders the intestinal canal antiseptic and is the most valued drug in intestinal affections." The anodyne properties of Antikamnia in connection with Salol render this tablet very useful in Dysentery, Indigestion, Cholera Morbus, Diarrhœa, Colic, and all conditions due to intestinal fermentation.

LAXATIVE ANTIKAMNIA & QUININE TABLETS

To reduce fever, quiet pain, and at the same time administer a gentle tonic-laxative is to accomplish a great deal with a single tablet. Among the many diseases and affections which call for such a combination, we might mention La Grippe, Influenza, Coryza, Coughs and Colds, Chills and Fever, Biliousness, Dengue and Malaria with its general discomfort and great debility.

ANTIKAMNIA & CODEINE TABLETS

Especially useful in Dysmenorrhœa, Utero-Ovarian Pain, and pain in general caused by suppressed or irregular menses. This tablet controls the pains of these disorders in the shortest time and by the most natural and economic method. The synergetic action of these drugs is *ideal*, for not only are their sedative and analgesic properties unsurpassed, but they are followed by no unpleasant effects. The efficacy of this tablet in neuroses of the larynx is well known.

THE ANTIKAMNIA CHEMICAL COMPANY

ST. LOUIS, U. S. A.

COMPLETE IN EIGHT VOLUMES

Reference Handbook of the Medical Sciences.

AN ENTIRELY REWRITTEN AND COMPLETELY REVISED EDITION.

To be published in EIGHT IMPERIAL OCTAVO VOLUMES, illustrated by chromo-lithographs and over five thousand engravings.

NO apology is deemed necessary in introducing to the medical profession the forthcoming revised edition of this great reference work, the sale of whose former edition far exceeded that of any other medical encyclopædia ever published. It is believed that the new Handbook will be welcomed not as a new and untried venture in medical book publishing, but rather as an old friend and ally, so much superior both in scientific completeness and mechanical execution as to render it indispensable alike to those who owned the original edition and learned by actual experience how great was its practical value, and to those who now for the first time will make its acquaintance.

This superb work covers so wide a field, and embraces such a large variety of topics, as to make it of the **greatest practical utility**, not only to general practitioners, but also to those who are interested more particularly in special departments of medical knowledge.

THE WORK CONSISTS OF A COLLECTION OF CONCISELY WRITTEN ESSAYS ON ALL THE IMPORTANT TOPICS BELONGING TO THE BROAD DOMAIN OF MEDICINE, SURGERY, AND THE ALLIED SCIENCES.

Its subject-matter is alphabetically arranged, thus admitting of instant and ready reference, with no loss of time in reading over page after page to find the precise item desired.

The topics are treated in such a thorough manner that the reader will rarely, if ever, find it necessary to consult larger special treatises or monographs for the information of which he may stand in need.

The great advance made in the quality of **illustrations**, through the discovery of new processes and the perfecting of mechanical technique, as well as from the greater experience and taste of those now superintending such matters, are apparent in the Reference Handbook. A great number of full-page plates, by chromo-lithography, photogravure, and other processes, is to be inserted. No pains or expense has been spared to make this work **the most sumptuously illustrated publication of recent times.**

The Reference Handbook is electrotyped from new type, especially made for it, and printed on extremely fine paper, which combines a high surface with the best wearing qualities; an important question in the case of a work of this sort.

The work will consist of eight splendid imperial octavo volumes, thoroughly illustrated. Each volume will contain about 800 pages, printed in double column, and each page containing as many words as are found upon three and one-half ordinary full octavo pages. The contents of the set will therefore **equal that of fifty or more large volumes of the usual octavo size.**

The Reference Handbook is designed to be a **constant daily companion** and **ready reference** on **all branches of Medicine, Surgery**, and the **collateral sciences.**

The Editor-in-Chief is Albert H. Buck, M.D., and over five hundred eminent specialists have agreed to contribute. No such number of prominent writers and teachers has ever before been associated together in the preparation of a work specially designed for the medical profession.

SOLD BY SUBSCRIPTION AT THE FOLLOWING PRICES:

In extra English muslin binding, per volume, -	**$7.00**
In brown leather, raised bands, per volume, - -	**8.00**
In extra Turkey Morocco, English cloth sides, per volume,	**9.00**

☞ Special terms and prices to owners of the former edition of the Reference Handbook.

The publishers will be pleased to furnish, on application, a descriptive circular, showing the scope of the work and a full list of department advisers and authors, with specimen pages.

Do not fail to apply for this circular.

WILLIAM WOOD AND COMPANY, 51, Fifth Avenue, New York.

VICHY CÉLESTINS

FRENCH REPUBLIC PROPERTY.

Bottled under the direct supervision of the FRENCH GOVERNMENT. **Not equaled in the world for medicinal use. Known for many centuries as the Best and Strongest Natural Alkaline Water.**

Promotes more active endosmose, neutralizes and washes out of the system all incompletely burnt bodies.

To give the name of Vichy water to a mere solution of bicarbonate of soda is as great an abuse of language as to give the name of wine to a mixture of cream of tartar, alcohol, and mineral salts which wine furnishes when analyzed.

Drink from the **natural spring,** says Sir Henry Thomson, F.R.C.S., *London.*

CAUTION.

So-called VICHY in BULK or SIPHON is not VICHY

VICHY IS NEVER IMPORTED OTHERWISE THAN IN BOTTLES.

General Agency, 220 Broadway, New York.

Morrison Surgical Pads

Nos. 372, 373 and 375. Nos. 377 and 378.

THESE Cushions are especially adapted for use on the operating table or Physician's office chair.

They are made of the best tan rubber, and are provided with an inflatable air cushion four inches wide at the upper end, and on the sides.

These Cushions possess *many advantages* over any other Surgical Cushion on the market. **FIRST**—*a very important one*, that the Cushion is made in such a manner *that it has no space or crevice between the cushion and the pad*, and when not inflated the whole pad is perfectly flat and smooth, *easily sterilized and thoroughly cleansed.*

The **SECOND** advantage is, that the Cushion being made in the manner as described above, *can be used on both sides*, which will be a great saving to Doctors who have to use many of them.

DAVIDSON RUBBER COMPANY, - Boston, Mass.

The Serum Diagnosis of Disease.

By RICHARD C. CABOT, M.D.,

Physician to Out-Patients, Massachusetts General Hospital.

Author of "A Guide to the Clinical Examination of the Blood."

In one octavo volume of 154 pages, illustrated. Price, $1.50 net. . .

THE ONLY UP-TO-DATE BOOK ON THE SUBJECT.

☞ This book aims to bring together in convenient form the results of the immense amount of work which has been done upon serum diagnosis since 1896.

The general practitioner as yet has not taken up the method of Serum Diagnosis, and it remains in the hands of a comparatively small number of men. This is a great pity, since the test is an exceedingly simple one, easily learned and quickly performed, and one needing no extra apparatus provided a good microscope is at hand. The cultures used in the test can be kept indefinitely at room temperature, and no thermostat is needed. The whole process can easily and safely be carried out by the physician in his office without any laboratory facilities and without half the skill or labor necessary to examine urinary sediments. I hope that this book may do something toward making the test more widely used outside of laboratories and in the hands of the general practitioner.

Treatise on Orthopedic Surgery

By EDWARD H. BRADFORD, M.D.

Surgeon to the Children's Hospital and to the Samaritan Hospital; Assistant Professor of Orthopedic Surgery, Harvard Medical School

AND

ROBERT W. LOVETT, M.D.

Assistant Surgeon to the Children's Hospital; Surgeon to the Infants' Hospital.

SECOND REVISED AND ENLARGED EDITION. Illustrated by Six Hundred and Twenty-one Engravings.

THE advance in Orthopedic Surgery in the last nine years has been so rapid that a revised edition of this work has necessitated very largely the rewriting of the entire book. But few changes in its scope or classification have been made.

Orthopedic Surgery, if properly defined, should include the prevention as well as the cure of deformity. For this reason the authors of this work have considered at some length the diseases of the joints, inasmuch as they are among the most common sources of deformity and disability. They have not confined themselves too closely to the definition of the term Orthopedic Surgery. Besides the consideration of joint disease and Pott's disease, there have been added brief descriptions of some disabling and deforming nervous affections, which are only discussed in their practical surgical aspect.

TABLE OF CONTENTS.

	PAGE
Preface	iii
CHAPTER I.	
Pott's Disease	1
CHAPTER II.	
Lateral Curvature of the Spine	79
CHAPTER III.	
Other Affections of the Spine	141

THE DUPLEX INHALER

The "Duplex" Anæsthetic Inhaler was primarily designed to lessen the danger and inconveniences incident to the use of an ordinary mask. The advantages claimed for it are:

1st. SAFE AND ACCURATE. It lessens the danger to the patient by allowing the use of definite mixture of anæsthetic saturated, and pure air in any proportions, not by giving a specified number of drops in a certain time, which in a still, close room may mean a great deal and in a freely ventilated one, very little, but by mixing air which is saturated with anæsthetic with that which contains none.

2nd. SUFFOCATION AVOIDED. By its use the patient can be brought under so gradually that struggling and a sense of suffocation are entirely avoided, so greatly decreasing the danger of the stage of excitement.

3rd. UNIFORM ANÆSTHESIA. The patient can be constantly kept at any point desired, not near the danger line of profound anæsthesia one minute and partially conscious the next. With the ordinary chloroform mask you at times get more of the anæsthetic than is desired and then at other times not sufficient, with the "Duplex" inhaler you get any desired quantity all the time.

4th. COMBINATION FEATURES. Chloroform, ether, nitrous oxide, ethyl chloride or bromide, oxygen or pure air can be given successively, together, alone, or in any combination not by mixing liquids which are volatized at different rates, but by mixing the gases or vapors due to their volatization in definite proportions. Changes can be instantly and conveniently made.

MANUAL OF ANTENATAL PATHOLOGY AND HYGIENE

THE FOETUS

By J. W. BALLANTYNE, M.D., F.R.C.P.E., F.R.S., Edin.
Lecturer on Midwifery and Gynecology, Medical College, Edinburgh

The subject is one of tremendous importance for the future of the race and the individual, inasmuch as it is one of preventative medicine in its simplest and most hopeful, because its earliest, aspects.

There are 14 exquisitely executed colored plates, representing transverse sections of the Fœtus, besides numerous illustrations in the text.

The book contains 543 pages, including a very complete index. It is large octavo in size, beautifully printed on super-calendered paper.

Price, bound in muslin, $5.00 net.

NEW YORK UNIVERSITY, Medical Department.

SCHOOL OF OPHTHALMOLOGY, OTOLOGY AND LARYNGOLOGY

FOR GRADUATES OF MEDICINE.

Clinics daily by the surgical staff of the Infirmary. Special course in Ophthalmoscopy, Refraction, Operative Surgery of the Eye and Ear, and Pathology.

The abundant clinical material at this well-known institution affords students an unusual opportunity for obtaining a practical knowledge of these special subjects. Two vacancies on the House Staff exist in January and July of each year. For particulars address the Secretary,

DR. GEORGE S. DIXON,
New York Eye and Ear Infirmary.

Northwestern University Medical School.

(CHICAGO MEDICAL COLLEGE.)

The regular course includes four years of eight months each. The laboratory equipment is complete. The clinical facilities are exceptionally fine. For circulars of detailed information, address the Secretary,

DR. ARTHUR R. EDWARDS,
2431 Dearborn Street, Chicago, Ill.

The Johns Hopkins University

MEDICAL DEPARTMENT

ESTABLISHED BY THE JOHNS HOPKINS UNIVERSITY AND IN CONNECTION WITH THE JOHNS HOPKINS HOSPITAL.

Instruction begins October 4, 1904. Candidates for admission must be graduates of an approved College, must present certificates of courses in Physics, Chemistry and Biology and possess a fair reading knowledge of French and German. The annual announcement, giving full details of entrance requirements and courses of instruction will be sent on application to the Dean.

A limited number of graduates in Medicine may be admitted as special workers at any time during the year, but not as candidates for a degree. Systematic instruction to graduates in medicine is provided during May and June; for details apply to the Dean of the Medical Department, Johns Hopkins University, Baltimore, Md.

WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA.

53d Annual Session. Thorough course. Four years. Exceptional facilities for Laboratory and Bedside Instruction. Full particulars in catalogue.

CLARA MARSHALL, M.D., Dean, Box 325, 21st St. & N. College Ave., Philadelphia, Pa.

Yale University.

The curriculum in the Medical School of this University is graded to extend through four years, and consists chiefly of *personal instruction* in Classroom, Laboratory, and Clinic with didactic lectures on certain branches.

The ninety-second annual session will begin September 29, 1904, and continue thirty-five weeks, exclusive of vacations.

For announcements of the curriculum, requirements for matriculation and graduation, apply to

DR. HERBERT E. SMITH, Dean,
Yale Medical School, New Haven, Conn.

HARVARD UNIVERSITY,

MEDICAL DEPARTMENT.

A School for Graduates in Arts or Science.

The course of study required for the degree of M.D. is of four years' duration. The next year begins September 29, 1904, and ends on the last Wednesday in June, 1905.

Courses for Graduates.—These courses of instruction are offered for graduates of recognized medical schools, and are given in subjects embracing all the branches of practical and scientific medicine.

The extensive laboratories of the school are inferior to none, and the clinical advantages afforded by the hospitals of Boston are unsurpassed.

Summer Courses.—During the summer courses in many branches of practical and scientific medicine are given by teachers in the school to both medical students and graduates.

Facilities for research work are offered in all of the laboratories.

For announcements of the Required Courses of Study in the School, the Courses for Graduates, and the Summer Courses, address Dr. Wm. L. Richardson, Dean, Harvard Medical School, 688 Boylston St. Boston Mass.

Jefferson Medical College of Philadelphia.

New College Building and New Laboratories.

The Eightieth Annual Session will begin September 24, 1904, and continue eight months. For four annual sessions the curriculum provides without extra fee: 1. Practical manual training in ten different laboratories recently fitted up at heavy cost. 2. Recitations by the faculty and others. 3. Didactic lectures and demonstrations in the commodious new buildings. 4. Clinics and bedside ward work in small groups at the College Hospital; besides the clinics given by the staff of the college at the Pennsylvania Philadelphia, German, St. Joseph's and Municipal Hospitals. 5. Lying-in cases at the College Maternity.

A NEW FIRE-PROOF HOSPITAL with unrivaled facilities for clinical teaching is now building at a cost of $800,000.

For circular and information, address

J. W. HOLLAND, Dean.

DISEASES OF WOMEN.

A CLINICAL GUIDE TO THEIR DIAGNOSIS AND TREATMENT.

By G. ERNEST HERMAN, M.B. (Lond.), F.R.C.P.

Obstetric Physician to and Lecturer on Midwifery at the London Hospital. Consulting Physician-Accoucheur to the Tower Hamlets Dispensary. Examiner in Midwifery to the Universities of London and Oxford.

SECOND REVISED EDITION.

One Volume of 900 pages, octavo, profusely illustrated. Muslin, $5.00 *net;* Leather, $5.75 *net.*

The wonderful success attending the publication of Dr. Herman's book "Diseases of Women" and so extensive its sale, and that of his "Difficult Labor," which has run through many editions, that a revised edition of the former work has been felt to be demanded.

Dr. Herman belongs to the progressive element of the profession. He appreciates the tendencies of the times, and here responds to their demands. He is nothing if not practical, and honest not only in the expression of his own convictions, but even to the extent of confessing ignorance on points which others perhaps less fitted to discuss would endeavor to elucidate.

By ALBERT H. BUCK, M.D.

Third Revised Edition.

Press Notice.—Suffice it to say that the one (*i. e.*, the book) now under discussion is the presentation of long years of clinical experience by one who has had unusually good opportunities for observation, and has improved them to the utmost. Three editions tell more than mere words can.—*New York Medical Journal*, January 21, 1899.

One volume of 604 pages, octavo, profusely illustrated by 147 wood-engravings. Extra muslin, $3.50 net.

Wounds in War.

THE MECHANISM OF THEIR PRODUCTION AND THEIR TREATMENT.

By Surgeon-Colonel W. F. Stevenson,

Professor of Military Surgery, Army Medical School, Netley, England.

The author remarks in the Preface: "As the improvements which have taken place in modern surgery have necessitated changes in the methods of treatment of gunshot wounds, as of all others, so also the very conditions themselves of these injuries have changed. The projectiles which, for the most part, cause them, and the small arms now in the hands of soldiers, are quite different from those formerly in use, and produce injuries, both of soft parts and of bone, quite unlike those seen in even the later campaigns.

"To indicate the lines on which the modern treatment of wounds in war should be carried out in special injuries of particular parts of the body, and to point out what methods are calculated to bring about the best results in the preservation of lives and limbs in individual cases, have been the objects aimed at in the following pages."

ADOPTED FOR FIELD USE BY THE SURGEON-GENERAL U. S. A.

One volume of 588 pages, octavo, profusely illustrated. Muslin, $4.00 *net*

LISTERINE

in

SUMMER COMPLAINT

The absolute safety of Listerine, its well defined antiseptic power, and the readiness with which it lends itself to combination with other indicated remedies, are properties which have led many physicians to adopt Listerine as the antiseptic foundation of their prescriptions for Summer Complaint.

A 32-page pamphlet on this subject, containing many valuable suggestions for treatment, may be had upon application.
